Numerical Constants

Fundamental Constants		
Name	**Symbol**	**Value**
Speed of light in vacuum	*c*	$2.99792458 \cdot 10^{8}\,\mathrm{m\,s^{-1}}$
Elementary charge	*e*	$1.602176634 \cdot 10^{-19}\,\mathrm{C}$
Universal gravitational constant	*G*	$6.67430\,(15) \cdot 10^{-11}\,\mathrm{m^{3}\,kg}$
Planck's constant	*h*	$6.62607015 \cdot 10^{-34}\,\mathrm{J\,s}$
Boltzmann's constant	k_B	$1.380649 \cdot 10^{-23}\,\mathrm{J\,K^{-1}}$
Avogadro's number	N_A	$6.02214076 \cdot 10^{23}\,\mathrm{mol^{-1}}$
Universal gas constant	*R*	$8.314462618...\,\mathrm{J\,mol^{-1}\,K^{-}}$
Mass of an electron	m_e	$9.1093837015\,(28) \cdot 10^{-31}$
Mass of a proton	m_p	$1.67262192369\,(51) \cdot 10^{-2}$
Mass of a neutron	m_n	$1.67492749804\,(95) \cdot 10^{-2}$
Coulomb force constant	*k*	$8.\,9875517923\,(14) \cdot 10^{9}\,\mathrm{N}$

Fundamental Constants		
Name	**Symbol**	**Value**
Magnetic permeability of free space	μ_0	$1.25663706212\,(19) \cdot 10^{-6}$
Electric permittivity of free space	$\epsilon_0 = 1/\left(\mu_0 C^2\right)$	$8.8541878128\,(13) \cdot 10^{-12}$
Stefan-Boltzmann constant	σ	$5.670374419\ldots \cdot 10^{-8}\,\mathrm{W\,m}$

Source: National Institute of Standards and Technology, http://physics.nist.gov/constants. The numbers in parentheses show the uncertainty in the final digits of the quoted number. For example, 6.67384(80) means 6.67384 ± 0.00080. Values shown without uncertainties are exact.

Other Useful Constants		
Name	**Symbol**	**Value**
Standard acceleration due to gravity	g	$9.81\,\mathrm{m\,s^{-2}}$
Standard atmospheric pressure at $20\,^\circ\mathrm{C}$	atm	$1.01325 \cdot 10^5\,\mathrm{Pa}$
Volume of ideal gas at $0\,^\circ\mathrm{C}$ and 1 atm		$22.41396954...\,\mathrm{liter/mol}$
Mechanical equivalent of heat		$4.186\,\mathrm{J/cal}$
Atomic mass unit	u	$1.660539066(50) \cdot 10^{(-27)}\,\mathrm{kg}$
Electron-volt	eV	$1.602176634 \cdot 10^{-19}\,\mathrm{J}$
Atomic mass unit energy equivalent	$\mathrm{u}c^2$	931.49410242(28) MeV
Electron mass energy equivalent	$m_\mathrm{e}C^2$	0.51099895000(15) MeV

Other Useful Constants		
Name	**Symbol**	**Value**
Proton mass energy equivalent	$m_{\mathrm{p}}C^2$	938.27208816(29) MeV
Neutron mass energy equivalent	$m_{\mathrm{n}}C^2$	939.56542052(54) MeV
Planck's constant divided by 2π	$\hbar$	$1.054571817... \cdot 10^{-34}\,\mathrm{J\,s}$
Planck's constant divided by 2π times c	$\hbar c$	197.3269804... MeV fm
Bohr radius	a_0	$0.529177210903\,(80) \cdot 10^{-10}\,\mathrm{m}$

Source: National Institute of Standards and Technology, http://physics.nist.gov/constants (2018 CODATA recommended values). The numbers in parentheses show the uncertainty in the final digits of the quoted number. For example, 6.67384(80) means 6.67384 ± 0.00080. Numbers quoted ending in .... show an exact value that can be computed to an arbiitrary number of digits.

$1\ \text{knot} = 1.151\ \text{mph} = 0.5144\ \text{m/s}$

Acceleration

$1\ \text{m/s}^2 = 100\ \text{cm/s}^2 = 3.281\ \text{ft/s}^2$
$1\ \text{cm/s}^2 = 0.01\ \text{m/s}^2 = 0.03281\ \text{ft/s}^2$
$1\ \text{ft/s}^2 = 0.3048\ \text{m/s}^2 = 30.48\ \text{cm/s}^2$

Mass

$1\ \text{kg} = 1000\ \text{g} = 0.0685\ \text{slug}$
$1\ \text{slug} = 14.59\ \text{kg}$
$1\ \text{kg} = 2.2046\ \text{lb}$
$1\ \text{lb} = 0.4536\ \text{kg}$

Force

$1\ \text{N} = 0.2248\ \text{lb}$
$1\ \text{lb} = 4.448\ \text{N}$
$1\ \text{stone} = 14\ \text{lb} = 62.28\ \text{N}$

Pressure

$1\ \text{Pa} = 1\ \text{N/m}^2 = 1.450 \cdot 10^{-4}\ \text{lb/in}^2 = 0.0209\ \text{lb/ft}^2$
$1\ \text{atm} = 1.013 \cdot 10^5\ \text{Pa} = 101.3\ \text{kPa} = 14.7\ \text{lb/in}^2 = 2117\ \text{lb/ft}^2 = 760\ \text{mm Hg} = 29.92\ \text{in Hg}$
$1\ \text{lb/in}^2 = 6895\ \text{Pa}$
$1\ \text{lb/ft}^2 = 47.88\ \text{Pa}$
$1\ \text{mm Hg} = 1\ \text{Torr} = 133.3\ \text{Pa}$
$1\ \text{bar} = 10^5\ \text{Pa} = 100\ \text{kPa}$

Energy

$1\ \text{J} = 0.239\ \text{cal}$
$1\ \text{cal} = 4.186\ \text{J}$
$1\ \text{Btu} = 1055\ \text{J} = 252\ \text{cal}$
$1\ \text{kW} \cdot \text{h} = 3.600 \cdot 10^6\ \text{J}$
$1\ \text{ft} \cdot \text{lb} = 1.356\ \text{J}$
$1\ \text{eV} = 1.602 \cdot 10^{-19}\ \text{J}$

Power

$1\ \text{W} = 1\ \text{J s}$
$1\ \text{hp} = 746\ \text{W} = 0.746\ \text{kW} = 550\ \text{ft} \cdot \text{lb/s}$
$1\ \text{Btu/h} = 0.293\ \text{W}$
$1\ \text{GW} = 1000\ \text{MW} = 1.0 \cdot 10^9\ \text{W}$

$1\,\mathrm{kW} = 1.34\,\mathrm{hp}$

Temperature

Fahrenheit to Celsius: $T_\mathrm{C} = \frac{5}{9}(T_\mathrm{F} - 32\ ^\circ\mathrm{F})$
Celsius to Fahrenheit: $T_\mathrm{F} = \frac{9}{5}T_\mathrm{C} + 32\ ^\circ\mathrm{C}$
Celsius to Kelvin: $T_\mathrm{K} = T_\mathrm{C} + 273.15\ ^\circ\mathrm{C}$
Kelvin to Celsius: $T_\mathrm{C} = T_\mathrm{K} - 273.15\,\mathrm{K}$

About the Authors

W. Bauer and G. D. Westfall

Wolfgang Bauer was born in Germany and obtained his Ph.D. in theoretical physics from the University of Giessen in 1987. After a post-doctoral fellowship at the California Institute of Technology, he joined the faculty at Michigan State University in 1988, with a dual appointment at the National Superconducting Cyclotron Laboratory (NSCL). He has worked on a large variety of topics in theoretical and computational physics, from high-temperature superconductivity to supernova explosions, but has been especially interested in relativistic nuclear collisions. In recent years, Dr. Bauer has focused much of his research and teaching on issues concerning energy, including fossil fuel resources, ways to use energy more efficiently, and, in particular, alternative and carbon-neutral energy resources. From 2001 to 2013, he served as chairperson of the Department of Physics and Astronomy. In 2009, he founded the Institute for Cyber-Enabled Research and served as its first director until 2013. From 2013 to 2020, he was a member of MSU's executive management, as Senior Consultant and Associate Vice President for Administration. He was a coauthor of MSU's Energy Transition Plan and the lead author of the Mobility Plan. In 2020, Dr. Bauer returned to the regular faculty and holds the title of University Distinguished Professor.

Gary D. Westfall started his career at the Center for Nuclear Studies at the University of Texas at Austin, where he completed his Ph.D. in experimental nuclear physics in 1975. From there he went to Lawrence Berkeley National Laboratory (LBNL) in

Berkeley, California, to conduct his post-doctoral work in high-energy nuclear physics and then stayed on as a staff scientist. While he was at LBNL, Dr. Westfall became internationally known for his work on the nuclear fireball model and the use of fragmentation to produce nuclei far from stability. In 1981, Dr. Westfall joined the National Superconducting Cyclotron Laboratory (NSCL) at Michigan State University (MSU) as a research professor; there he conceived, constructed, and ran the MSU 4π Detector. His research using the 4π Detector produced information concerning the response of nuclear matter as it is compressed in a supernova collapse. In 1987, Dr. Westfall joined the Department of Physics and Astronomy at MSU while continuing to carry out his research at NSCL. In 1994, Dr. Westfall joined the STAR Collaboration, which is carrying out experiments at the Relativistic Heavy Ion Collider (RHIC) at Brookhaven National Laboratory on Long Island, New York. Dr. Westfall is best known for his work with correlations and fluctuations of particle produced in Au+Au collisions at RHIC. In 2003, he was named University Distinguished Professor at Michigan State University. Dr. Westfall served as Chair of the RHIC Users Executive Committee and as the Chair of STAR Council. Dr. Westfall currently holds the title of University Distinguished Professor, Emeritus, at Michigan State University. Dr. Westfall received the Award for Innovative Excellence in Teaching, Learning, and Technology from the American Association of Physics Teachers, and he was a finalist for the Ernest L Boyer International Award for Innovative Excellence in Teaching, Learning, and Technology.

The Westfall/Bauer Partnership Drs. Bauer and Westfall have collaborated on nuclear physics research and on physics education research for more than two decades. The partnership started in 1988, when both authors were speaking at the same conference and decided to go downhill skiing together after the session. On this occasion, Westfall recruited Bauer to join the faculty at Michigan State University (in part by threatening to push him off the ski lift if he declined). They obtained NSF funding to develop novel teaching and laboratory techniques, authored multimedia

physics CDs for their students at the Lyman Briggs School, and coauthored a textbook on CD-ROM, called *cliXX Physik*. In 1992, they became early adopters of the Internet for teaching and learning by developing the first version of their online homework system. In subsequent years, they were instrumental in creating the Learning*Online* Network with CAPA, which is now used at more than 70 universities and colleges in the United States and around the world. From 2008 to 2013, Bauer and Westfall were part of a team of instructors, engineers, and physicists who investigate the use of peer-assisted learning in the introductory physics curriculum. This project has received funding from the NSF STEM Talent Expansion Program, and its best practices have been incorporated into this textbook.

Dedication This book is dedicated to our families. Without their patience, encouragement, and support, we could never have completed it.

A Note from the Authors

We are thrilled to introduce the third edition of our textbook, *University Physics*. Physics is a thriving science, alive with intellectual challenge and presenting innumerable research problems on topics ranging from the largest galaxies to the smallest subatomic particles. Physicists have managed to bring understanding, order, consistency, and predictability to our universe and will continue that endeavor into the exciting future.

However, when we open most current introductory physics textbooks, we find that a different story is being told. Physics is painted as a completed science in which the major advances happened at the time of Newton, or perhaps early in the 20th century. Only toward the end of the standard textbooks is "modern" physics covered, and even that coverage often includes only discoveries made through the 1960s.

Our main motivation in writing this book is to change this perception by weaving exciting, contemporary physics throughout the text. Physics is an amazingly dynamic discipline—continuously on the verge of new discoveries and life-changing applications. To help students see this, we need to tell the full, absorbing story of our science by integrating contemporary physics into the first-year calculus-based course. Even the very first semester offers many opportunities to do this by weaving recent results from nonlinear dynamics, chaos, complexity, and high-energy physics research into the introductory curriculum. Because we are actively carrying out research in these fields, we know that many of the cutting-edge results are accessible in their essence to the first-year student.

Recent results involving renewable energy, the environment, engineering, medicine, and technology show physics as an exciting, thriving, and intellectually alive subject motivating students, invigorating classrooms, and making the instructor's job easier and more enjoyable. In particular, we believe that talking about the broad topic of energy provides a great opening gambit to capture students' interest. Concepts of energy sources (fossil, renewable, nuclear, and so forth), energy efficiency, energy

storage, alternative energy sources, and environmental effects of energy supply choices (global warming and ocean acidification, for example) are very much accessible on the introductory physics level. We find that discussions of energy spark our students' interest like no other current topic, and we have addressed different aspects of energy throughout our book.

In addition to being exposed to the exciting world of physics, students benefit greatly from gaining the ability to **problem solve and think logically about a situation**. Physics is based on a core set of ideas that is fundamental to all of science. We acknowledge this and provide a useful problem-solving method (outlined in Chapter 1) which is used throughout the entire book. This problem-solving method involves a multistep format that we have developed with students in our classes. But mastery of concepts also involves actively applying them. To this end, we have asked more than a dozen contributors from some of the leading universities across the country to share their best work in the end-of-chapter exercises. We are particularly proud of approximately 400 multi-version exercises, which allow students to address the same problem from different perspectives.

Malcolm Fife/Getty Images

In 2012, the National Research Council published a framework for K-12 science education, which covers the essential science and engineering practices, the concepts that have application across fields, and the core ideas in four disciplinary areas (in physics, these are matter and its interactions, motion and stability, energy, and waves and their applications in information transfer). We have structured the third edition of this textbook to tie the

undergraduate physics experience to this framework and have provided concept checks and self-test opportunities in each chapter. In the ebook version of this third edition, we are also providing approximately 200 apps that allow the students to watch video clips of selected lecture demonstrations, as well as perform interactive physics simulations, which hopefully will lead to deeper understanding of physics concepts.

With all of this in mind, along with the desire to write a captivating textbook, we have created what we hope will be a tool to engage students' imaginations and to better prepare them for future courses in their chosen fields (admittedly, hoping we can convert at least a few students to physics majors along the way). Having feedback from more than 400 people, including a board of advisors, several contributors, manuscript reviewers, and focus group participants, assisted greatly in this enormous undertaking, as did field testing our ideas with more than 10,000 students in our introductory physics classes at Michigan State University. We thank you all!

—Wolfgang Bauer and Gary D. Westfall

How to Use This Book

Problem-Solving Skills: Learning to Think Like a Scientist

Perhaps one of the greatest skills students can take from their physics course is the ability to **problem solve and think critically about a situation.** Physics is based on a core set of fundamental ideas that can be applied to various situations and problems. *University Physics* by Bauer and Westfall acknowledges this and provides a problem-solving method that has been class-tested by the authors, which is used throughout the text. The text's problem-solving method has a multistep format.

Problem-Solving Method

Solved Problems

The book's numbered **Solved Problems** are fully worked problems, each consistently following the seven-step method described in Section 1.5. Each Solved Problem begins with the problem statement and then provides a complete solution. The seven-step method is also used in Connect Physics. The familiar seven steps are outlined in the guided solutions, with additional help where you need it.

SOLVED PROBLEM 13.2 Weighing Earth's Atmosphere

The Earth's atmosphere is composed (by volume) of 78.08% nitrogen (N_2), 20.95% oxygen (O_2), 0.93% argon (Ar), 0.25% water vapor (H_2O), and traces of other gases, most importantly, carbon dioxide (CO_2). The CO_2 content of the atmosphere is currently (year 2022) around 0.042% = 420 ppm (parts per million), but it varies with the seasons by about 6–7 ppm and has been rising since the start of the Industrial Revolution, mainly as a result of the burning of fossil fuels. Approximately 2 ppm of CO_2 are being added to the atmosphere each year.

PROBLEM

What is the mass of the Earth's atmosphere, and what is the mass of 1 ppm of atmospheric CO_2?

SOLUTION

THINK At first glance, this problem seems rather daunting because very little information is given. However, we know that the atmospheric pressure is $1.01 \cdot 10^5$ Pa and that pressure is force per area.

SKETCH The sketch in Figure 13.13 shows a column of air with weight mg above an area A of Earth's surface. This air exerts a pressure, p, on the surface.

RESEARCH We start with the relationship between pressure and force, $p = F/A$, where the area is the surface area of Earth, $A = 4\pi R^2$, and $R = 6370$ km is the radius of Earth. For the force, we can use the atmospheric weight, $F = mg$, where m is the mass of the atmosphere.

SIMPLIFY We combine the equations just mentioned

$$p = \frac{F}{A} = \frac{mg}{4\pi R^2}$$

and solve for the mass of the atmosphere

$$m = \frac{4\pi R^2 p}{g}.$$

CALCULATE We substitute the numerical values:

$$m = 4\pi(6.37 \cdot 10^6 \text{ m})^2(1.01 \cdot 10^5 \text{ Pa})/(9.81 \text{ m/s}^2) = 5.24978 \cdot 10^{18} \text{ kg}.$$

ROUND We round to three significant figures and obtain

$$m = 5.25 \cdot 10^{18} \text{ kg}.$$

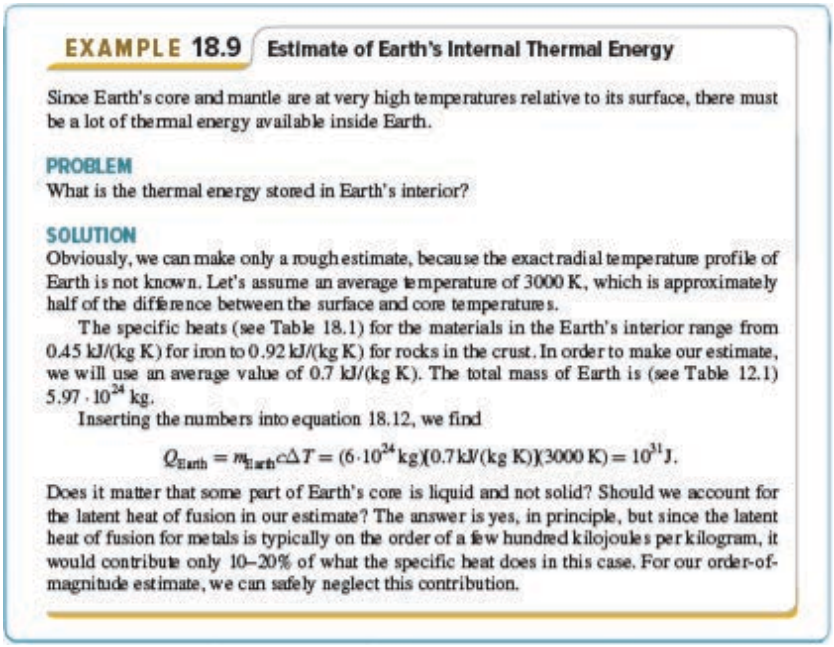
DOUBLE-CHECK In order to obtain the mass of 1 ppm of CO_2 in the atmosphere, we have to realize that the molar mass of CO_2 is $12 + (2 \cdot 16) = 44$ g. The average mass of a mole of the atmosphere is approximately $0.78(2 \cdot 14) + 0.21(2 \cdot 16) + 0.01(40) = 28.96$ g. The mass of 1 ppm of CO_2 in the atmosphere is therefore

$$m_{1 \text{ ppm } CO_2} = 10^{-6} \cdot m \frac{44}{28.96} = 7.97 \cdot 10^{12} \text{kg} = 8.0 \text{ billion tons}.$$

Humans add approximately 2 ppm of CO_2 to the atmosphere each year by burning fossil fuels, which amounts to approximately 16 billion tons of CO_2, a scary number. For comparison, the combined mass of all 8 billion humans on the planet is approximately 0.5 billion tons. Humans add more than 30 times our own weight in carbon dioxide to the atmosphere each year. It is not easy to double-check the orders of magnitude for this calculation. However, data published by the U.S. Energy Information Administration show that total carbon dioxide emissions from burning fossil fuels are currently approximately 30 billion tons per year, higher than our result by a factor of 2. Where does the other half of the CO_2 go? Mainly, it dissolves in the Earth's oceans.

Examples

Briefer **Examples** (problem statement and solution only) focus on a specific point or concept. The Examples also serve as a bridge between fully worked-out Solved Problems (with all seven steps) and the homework problems.



EXAMPLE 18.9 **Estimate of Earth's Internal Thermal Energy**

Since Earth's core and mantle are at very high temperatures relative to its surface, there must be a lot of thermal energy available inside Earth.

PROBLEM

What is the thermal energy stored in Earth's interior?

SOLUTION

Obviously, we can make only a rough estimate, because the exact radial temperature profile of Earth is not known. Let's assume an average temperature of 3000 K, which is approximately half of the difference between the surface and core temperatures.

The specific heats (see Table 18.1) for the materials in the Earth's interior range from 0.45 kJ/(kg K) for iron to 0.92 kJ/(kg K) for rocks in the crust. In order to make our estimate, we will use an average value of 0.7 kJ/(kg K). The total mass of Earth is (see Table 12.1) $5.97 \cdot 10^{24}$ kg.

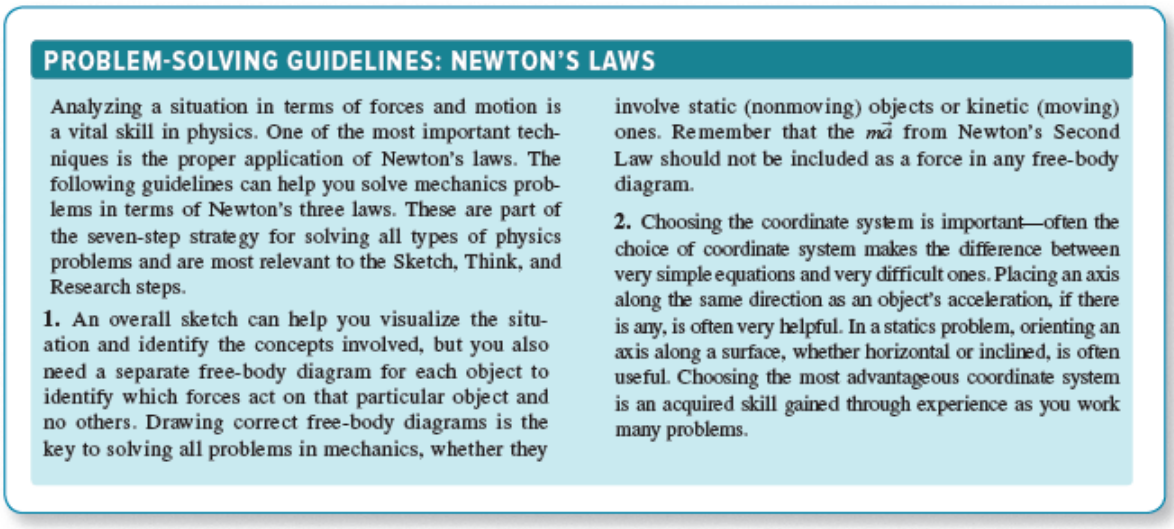
Inserting the numbers into equation 18.12, we find

$$Q_{\text{Earth}} = m_{\text{Earth}} c \Delta T = (6 \cdot 10^{24}\,\text{kg})(0.7\,\text{kJ/(kg K)})(3000\,\text{K}) = 10^{31}\,\text{J}.$$

Does it matter that some part of Earth's core is liquid and not solid? Should we account for the latent heat of fusion in our estimate? The answer is yes, in principle, but since the latent heat of fusion for metals is typically on the order of a few hundred kilojoules per kilogram, it would contribute only 10–20% of what the specific heat does in this case. For our order-of-magnitude estimate, we can safely neglect this contribution.

Problem-Solving Guidelines

Located before the end-of-chapter exercise sets, **Problem-Solving Guidelines** summarize important skills or techniques that can help you solve problems related to the material in the chapter. Acknowledging that physics is based on a core set of fundamental ideas that can be applied to various situations and problems, *University Physics* emphasizes that there is no single way to solve every problem and helps you think critically about the most effective problem-solving method before beginning to work on a solution.



PROBLEM-SOLVING GUIDELINES: NEWTON'S LAWS

Analyzing a situation in terms of forces and motion is a vital skill in physics. One of the most important techniques is the proper application of Newton's laws. The following guidelines can help you solve mechanics problems in terms of Newton's three laws. These are part of the seven-step strategy for solving all types of physics problems and are most relevant to the Sketch, Think, and Research steps.

1. An overall sketch can help you visualize the situation and identify the concepts involved, but you also need a separate free-body diagram for each object to identify which forces act on that particular object and no others. Drawing correct free-body diagrams is the key to solving all problems in mechanics, whether they involve static (nonmoving) objects or kinetic (moving) ones. Remember that the $m\vec{a}$ from Newton's Second Law should not be included as a force in any free-body diagram.

2. Choosing the coordinate system is important—often the choice of coordinate system makes the difference between very simple equations and very difficult ones. Placing an axis along the same direction as an object's acceleration, if there is any, is often very helpful. In a statics problem, orienting an axis along a surface, whether horizontal or inclined, is often useful. Choosing the most advantageous coordinate system is an acquired skill gained through experience as you work many problems.

End-of-Chapter Questions and Exercise Sets

Along with providing problem-solving guidelines, examples, and strategies, *University Physics* also offers a **wide variety of end-of-chapter Questions and Exercises.** Included in each chapter are Multiple-Choice Questions, Conceptual Questions, Exercises (by section), Additional Exercises (no section "clue"), and Multi-Version Exercises. One bullet identifies slightly more challenging Exercises, and two bullets identify the most challenging Exercises.

Calculus Primer

Since this course is typically taken in the first year of study at universities, this book assumes knowledge of high school physics and mathematics. It is preferable that students have had a course in calculus before they start this course, but calculus can also be taken in parallel. To facilitate this, the text contains a short calculus primer in an appendix, giving the main results of calculus without the rigorous derivations.

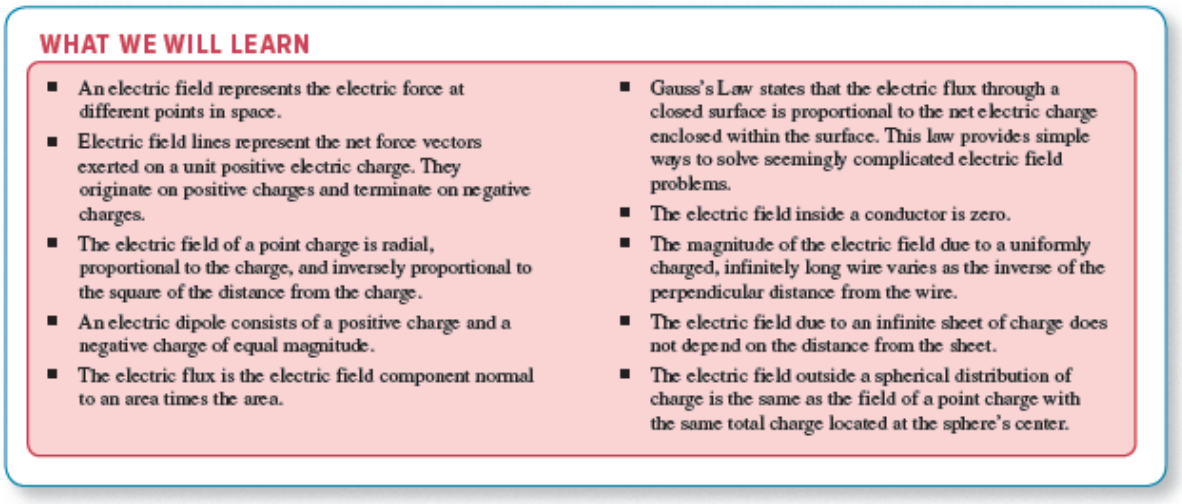
Building Conceptual Understanding

Chapter Opening Outline

At the beginning of each chapter is an outline presenting the section heads within the chapter. The outline also includes the titles of the Examples and Solved Problems found in the chapter. At a quick glance, you will know if a desired topic, example, or problem is in the chapter.

What We Will Learn / What We Have Learned

Each chapter of *University Physics* is organized like a good research seminar. It was once said, "Tell them what you will tell them, then tell them, and then tell them what you told them!" Each chapter starts with **What We Will Learn**—a quick summary of the main points, without any equations. And at the end of each chapter, **What We Have Learned/Exam Study Guide** contains key concepts, including major equations.



WHAT WE WILL LEARN

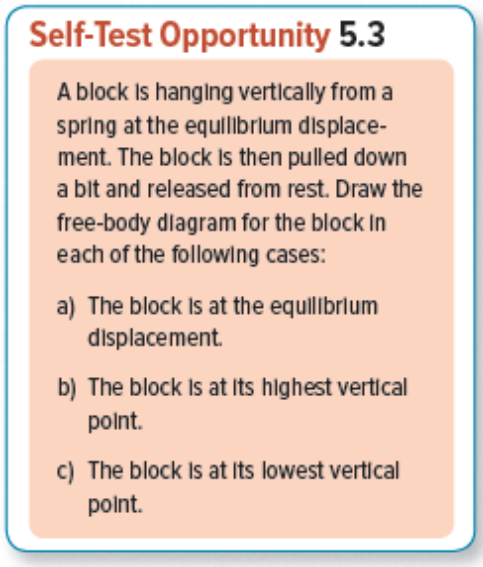
- An electric field represents the electric force at different points in space.
- Electric field lines represent the net force vectors exerted on a unit positive electric charge. They originate on positive charges and terminate on negative charges.
- The electric field of a point charge is radial, proportional to the charge, and inversely proportional to the square of the distance from the charge.
- An electric dipole consists of a positive charge and a negative charge of equal magnitude.
- The electric flux is the electric field component normal to an area times the area.
- Gauss's Law states that the electric flux through a closed surface is proportional to the net electric charge enclosed within the surface. This law provides simple ways to solve seemingly complicated electric field problems.
- The electric field inside a conductor is zero.
- The magnitude of the electric field due to a uniformly charged, infinitely long wire varies as the inverse of the perpendicular distance from the wire.
- The electric field due to an infinite sheet of charge does not depend on the distance from the sheet.
- The electric field outside a spherical distribution of charge is the same as the field of a point charge with the same total charge located at the sphere's center.

Conceptual Introductions

Conceptual explanations are provided in the text prior to any mathematical explanations, formulas, or derivations in order to establish why the concept or quantity is needed, why it is useful, and why it must be defined accurately. The authors then move from the conceptual explanation and definition to a formula and exact terms.

Self-Test Opportunities

In each chapter, a series of questions focus on major concepts within the text to encourage students to develop an internal dialogue. These questions will help students think critically about what they have just read, decide whether they have a grasp of the concept, and develop a list of follow-up questions to ask in class. The answers to the Self-Tests are found at the end of each chapter.



Self-Test Opportunity 5.3

A block is hanging vertically from a spring at the equilibrium displacement. The block is then pulled down a bit and released from rest. Draw the free-body diagram for the block in each of the following cases:

a) The block is at the equilibrium displacement.

b) The block is at its highest vertical point.

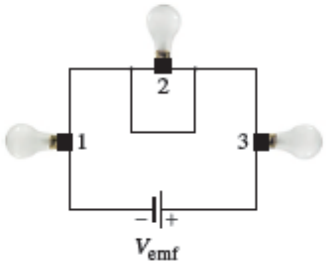
c) The block is at its lowest vertical point.

Concept Checks

Concept Checks are designed to be used with personal response system technology. They will appear in the text so that you may begin contemplating the concepts. Answers will only be available to instructors.

Concept Check 25.8

Three light bulbs are connected in series with a battery that delivers a constant potential difference, V_{emf}. When a wire is connected across light bulb 2 as shown in the figure, light bulbs 1 and 3



a) burn just as brightly as they did before the wire was connected.

b) burn more brightly than they did before the wire was connected.

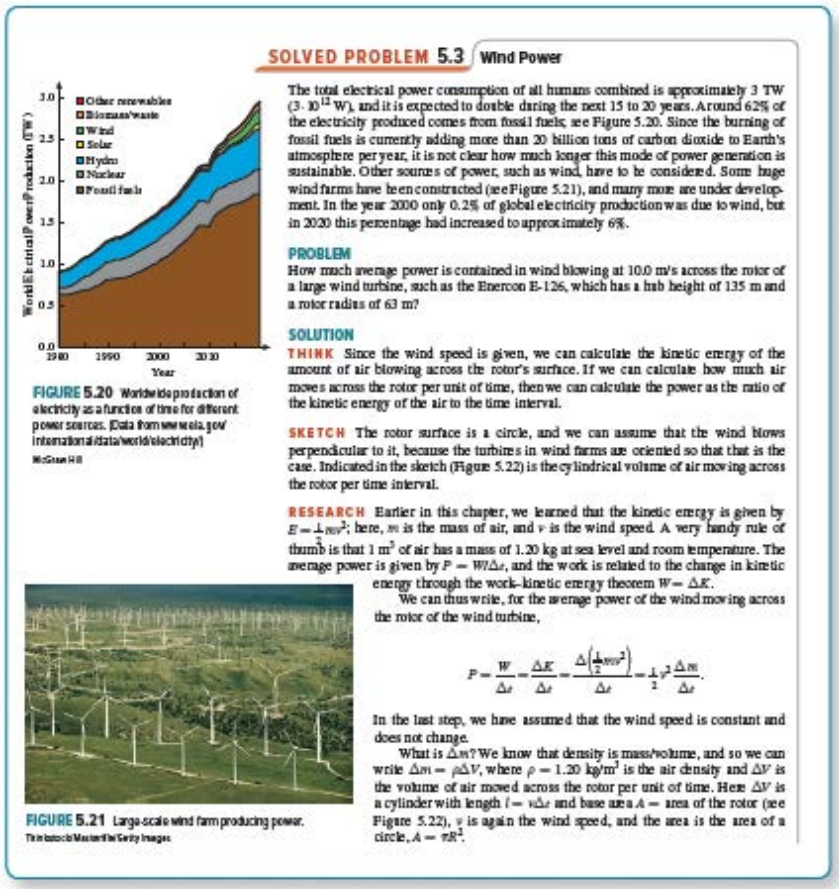
c) burn less brightly than they did before the wire was connected.

d) go out.

Seeing the Big Picture

Contemporary Examples

The authors have included recent physics research results throughout the text. Results involving renewable energy, the environment, aerospace, engineering, medicine, and technology demonstrate that physics is an exciting, thriving, and intellectually stimulating field. Available in Connect, the student resource center provides a number of items to enhance your understanding and help you prepare for lectures, labs, and tests.



SOLVED PROBLEM 5.3 Wind Power

FIGURE 5.20 Worldwide production of electricity as a function of time for different power sources. (Data from www.eia.gov/international/data/world/electricity)

The total electrical power consumption of all humans combined is approximately 3 TW ($3 \cdot 10^{12}$ W), and it is expected to double during the next 15 to 20 years. Around 62% of the electricity produced comes from fossil fuels; see Figure 5.20. Since the burning of fossil fuels is currently adding more than 30 billion tons of carbon dioxide to Earth's atmosphere per year, it is not clear how much longer this mode of power generation is sustainable. Other sources of power, such as wind, have to be considered. Some huge wind farms have been constructed (see Figure 5.21), and many more are under development. In the year 2000 only 0.2% of global electricity production was due to wind, but in 2020 this percentage had increased to approximately 6%.

PROBLEM

How much average power is contained in wind blowing at 10.0 m/s across the rotor of a large wind turbine, such as the Enercon E-126, which has a hub height of 135 m and a rotor radius of 63 m?

SOLUTION

THINK Since the wind speed is given, we can calculate the kinetic energy of the amount of air blowing across the rotor's surface. If we can calculate how much air moves across the rotor per unit of time, then we can calculate the power as the ratio of the kinetic energy of the air to the time interval.

SKETCH The rotor surface is a circle, and we can assume that the wind blows perpendicular to it, because the turbines in wind farms are oriented so that that is the case. Indicated in the sketch (Figure 5.22) is the cylindrical volume of air moving across the rotor per time interval.

RESEARCH Earlier in this chapter, we learned that the kinetic energy is given by $E = \frac{1}{2}mv^2$; here, m is the mass of air, and v is the wind speed. A very handy rule of thumb is that 1 m^3 of air has a mass of 1.20 kg at sea level and room temperature. The average power is given by $P = W/\Delta t$, and the work is related to the change in kinetic energy through the work–kinetic energy theorem $W = \Delta K$.

We can thus write, for the average power of the wind moving across the rotor of the wind turbine,

$$P = \frac{W}{\Delta t} = \frac{\Delta K}{\Delta t} = \frac{\Delta\left(\frac{1}{2}mv^2\right)}{\Delta t} = \frac{1}{2}v^2\frac{\Delta m}{\Delta t}.$$

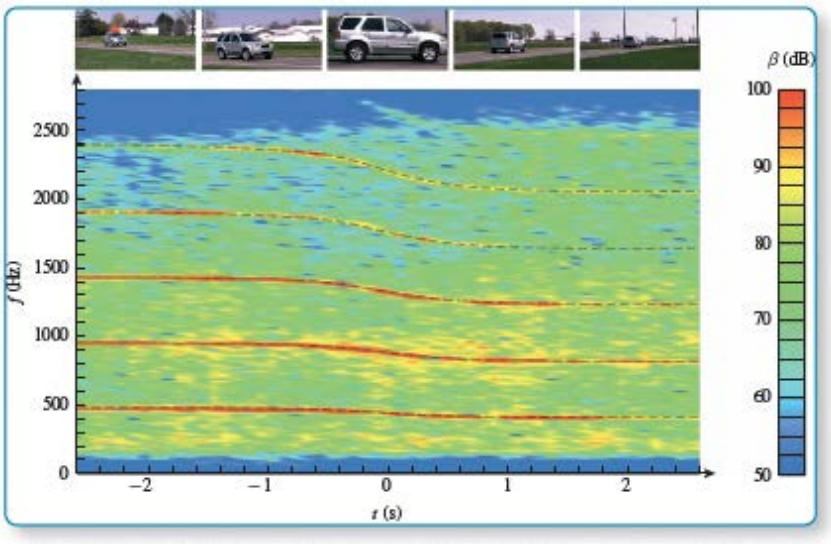
In the last step, we have assumed that the wind speed is constant and does not change.

What is Δm? We know that density is mass/volume, and so we can write $\Delta m = \rho\Delta V$, where $\rho = 1.20$ kg/m^3 is the air density and ΔV is the volume of air moved across the rotor per unit of time. Here ΔV is a cylinder with length $l = v\Delta t$ and base area $A =$ area of the rotor (see Figure 5.22), v is again the wind speed, and the area is the area of a circle, $A = \pi R^2$.

FIGURE 5.21 Large-scale wind farm producing power.

eBook

Linked to multimedia assets—including author videos, applets that allow you to explore fundamental physics principles, and images—the eBook allows you to take notes, highlight, and even search for specific words or phrases. All of the textbook figures, videos, and interactive content are also listed in line and by chapter, so you can navigate directly to the resource you need. Links to the eBook are included in the online homework and SmartBook 2.0. assignments, so if you are having trouble with an exercise or concept, you can navigate directly to the relevant portion of the text.



W. Bauer and G. D. Westfall

Visual Program

Familiarity with graphics and animation on the Internet and in video games has raised the bar for the graphical presentations in textbooks, which must now be more sophisticated to excite both students and faculty. Here are some of the techniques and ideas implemented in *University Physics:*

- Line drawings are superimposed on photographs to connect sometimes very abstract physics concepts to students' realities and everyday experiences.
- A three-dimensional look for line drawings adds plasticity to the presentations. Mathematically accurate graphs and plots were created by the authors in software programs such as Mathematica and then used by the graphic artists to ensure complete accuracy as well as a visually appealing style.

Study anytime, anywhere

Download the free ReadAnywhere® app and access your online eBook, SmartBook® 2.0, or Adaptive Learning Assignments when it's convenient, even if you're offline. And since the app automatically syncs with your Connect account, all of your work is available every time you open it. Find out more at **mheducation.com/readanywhere**

iPhone: Getty Images

"I really liked this app—it made it easy to study when you don't have your textbook in front of you."

- Jordan Cunningham, Eastern Washington University

Everything you need in one place

Your Connect course has everything you need—whether reading your digital eBook or completing assignments for class, Connect makes it easy to get your work done.

Learning for everyone

McGraw Hill works directly with Accessibility Services Departments and faculty to meet the learning needs of all students. Please contact your Accessibility Services Office and ask them to email accessibility@mheducation.com, or visit **mheducation.com/about/accessibility** for more information.

Digital Resources

Online Resources

A collection of online tools—including photos, artwork, an *Instructor's Solutions Manual,* and other media—can be accessed from the *University Physics* Connect library. These tools provide content for novice and experienced instructors who teach in a variety of styles. Included in the collection are PowerPoint slides containing full-color digital files of all illustrations in the text, a collection of digital files of photographs from the text, libraries of all the solved problems, examples, tables, and numbered equations from the text, and ready-made PowerPoint lecture outlines that include art, lecture notes, and additional examples for each section of the text. An *Instructor's Solutions Manual* with complete worked-out solutions to all of the end-of-chapter Questions and Exercises is available. The latest research in physics education shows that in-class use of personal response systems (or "clickers") improves student learning, so a full set of clicker questions based on the Concept Checks from the text is available on the companion website.

The Connect library also provides a number of author-provided applets to help you visualize physics concepts that are presented throughout the book—from vectors and kinematics to quantum and nuclear physics. Interactive simulations allow you to simulate real experiments, while viewing data in real time, thereby linking concepts and principles you have just learned to real, quantifiable results.

Student Solutions Manual

The *Student Solutions Manual* contains answers and worked-out solutions to selected end-of-chapter Questions and Exercises (those indicated by a blue number). Worked-out solutions for all items in Chapters 1 through 13 follow the complete seven-step problem-solving method introduced in Section 1.5. Chapters 14 through 40 continue to use the seven-step method for challenging (one bullet) and most challenging (two bullet) exercises, but present more abbreviated solutions for the less challenging (no bullet) exercises.

Proctorio

Remote Proctoring and Browser-Locking Capabilities

Remote proctoring and browser-locking capabilities, hosted by Proctorio within Connect, provide control of the assessment environment by enabling security options and verifying the identity of the student.

Seamlessly integrated within Connect, these services allow instructors to control the assessment experience by verifying identification, restricting browser activity, and monitoring student actions.

Instant and detailed reporting gives instructors an at-a-glance view of potential academic integrity concerns, thereby avoiding personal bias and supporting evidence-based claims.

Free-Body Diagram Tool

Drawing a free-body diagram is one of the first steps in solving problems that involve forces acting on objects. Using this tool, students are able to learn this important skill in an interactive fashion. In multiple real-world applications, this tool allows the students to draw several force vectors within appropriate error margins, check their work, make corrections, and in the end see the correct solution. Students get more practice opportunities, and instructors save time grading.

Virtual Labs for Physics

With McGraw Hill Virtual Labs for Physics, the lab is always open. These virtual lab experiments provide a flexible online lab solution for preparation, supplement, replacement, or use with a textbook to bridge the gap between the lecture and lab. Accessible simulations help students learn the data acquisition and analysis skills needed, then check for understanding and provide feedback. With pre-lab and post-lab assessment available, instructors can customize each assignment.

Test Builder in Connect

Available within Connect, Test Builder is a cloud-based tool that enables instructors to format tests that can be printed, administered within a Learning Management System, or exported as a Word document. Test Builder offers a modern, streamlined interface for easy content configuration that matches course needs, without requiring a download.

Test Builder allows you to:

- access all Test Bank content from a particular title.
- easily pinpoint the most relevant content through robust filtering options.
- manipulate the order of questions or scramble questions and/or answers.

- pin questions to a specific location within a test.
- determine your preferred treatment of algorithmic questions.
- choose the layout and spacing.
- add instructions and configure default settings.

Test Builder provides a secure interface for better protection of content and allows for just-in-time updates to flow directly into assessments.

Writing Assignment

Available within Connect and Connect Master, the Writing Assignment tool delivers a learning experience to help students improve their written communication skills and conceptual understanding. As an instructor, you can assign, monitor, grade, and provide feedback on writing more efficiently and effectively.

ReadAnywhere®

Read or study when it's convenient for you with McGraw Hill's free ReadAnywhere® app. Available for iOS or Android smartphones or tablets, ReadAnywhere gives users access to McGraw Hill tools including the eBook and SmartBook® 2.0 or Adaptive Learning Assignments in Connect. Take notes, highlight, and complete assignments offline–all of your work will sync when you open the app with Wi-Fi access. Log in with your McGraw Hill Connect username and password to start learning–anytime, anywhere!

Tegrity: Lectures 24/7

Tegrity in Connect is a tool that makes class time available 24/7 by automatically capturing every lecture. With a simple one-click start-and-stop process, you capture all computer screens and corresponding audio in a format that is easy to search, frame by frame. Students can replay any part of any class with easy-to-use, browser-based viewing on a PC, Mac, or mobile device.

Educators know that the more students can see, hear, and experience class resources, the better they learn. In fact, studies prove it. Tegrity's unique search feature helps students efficiently find what they need, when they need it, across an entire semester of class recordings. Help turn your students' study time into learning moments immediately supported by your lecture. With Tegrity, you also increase intent listening and class participation by easing students' concerns about note-taking. Using Tegrity in Connect will make it more likely you will see students' faces, not the tops of their heads.

Create

Your Book, Your Way

McGraw Hill's Content Collections Powered by Create® is a self-service website that enables instructors to create custom course materials—print and eBooks—by drawing upon McGraw Hill's comprehensive, cross-disciplinary content. Choose what you want from our high-quality textbooks, articles, and cases. Combine it with your own content quickly and easily, and tap into other rights-secured, third-party content such as readings, cases, and articles. Content can be arranged in a way that makes the most sense for your course, and you can include the course name and information as well. Choose the best format for your course: color print, black-and-white print, or eBook. The eBook can be included in your Connect course and is available on the free ReadAnywhere® app for smartphone or tablet access as well. When you are finished customizing, you will receive a free digital copy to review in just minutes! Visit McGraw Hill Create®–www.mcgrawhillcreate.com–today and begin building!

Reflecting the Diverse World Around Us

McGraw Hill believes in unlocking the potential of every learner at every stage of life. To accomplish that, we are dedicated to creating products that reflect, and are accessible to, all the diverse, global customers we serve. Within McGraw Hill, we foster a culture of belonging, and we work with partners who share our commitment to equity, inclusion, and diversity in all forms. In McGraw Hill Higher Education, this includes, but is not limited to, the following:

- Refreshing and implementing inclusive content guidelines around topics including generalizations and stereotypes, gender, abilities/disabilities, race/ethnicity, sexual orientation, diversity of names, and age.
- Enhancing best practices in assessment creation to eliminate cultural, cognitive, and affective bias.
- Maintaining and continually updating a robust photo library of diverse images that reflect our student populations.
- Including more diverse voices in the development and review of our content.
- Strengthening art guidelines to improve accessibility by ensuring meaningful text and images are distinguishable and perceivable by users with limited color vision and moderately low vision.

Acknowledgments

A book like the one that you are holding in your hands is impossible to produce without tremendous work by an incredible number of dedicated individuals. First and foremost, we would like to thank the talented editorial, production, and marketing team from McGraw Hill who worked on the third edition of the text: Theresa Collins, Beth Bettcher, Jeni McAtee, Naveen Jhaldiyal, Lorraine Buczek, and Lisa Granger. Their team spirit, good humor, and unbending optimism kept us on track and always made it fun for us to put in the seemingly endless hours it took to produce the manuscript.

The McGraw Hill team, as well as the reviewers and our board of advisors, deserve a large share of the credit for improving the quality of the final manuscript. Our colleagues on the faculty of the Department of Physics and Astronomy at Michigan State University—Alexandra Gade, Alex Brown, Bernard Pope, Carl Schmidt, Chong-Yu Ruan, C.P. Yuan, Dan Stump, Ed Brown, Hendrik Schatz, Kris Starosta, Lisa Lapidus, Michael Harrison, Michael Moore, Reinhard Schwienhorst, Salemeh Ahmad, S.B. Mahanti, Scott Pratt, Stan Schriber, Tibor Nagy, and Thomas Duguet—helped us in innumerable ways as well, teaching their classes and sections with the materials developed by us and in the process providing invaluable feedback on what worked and what needed additional refinement. We thank all of them. We also thank all of our problem contributors for sharing some of their best work with us, in particular, Richard Hallstein, who took on the task of organizing and processing all the contributions.

Finally, we could not have made it through the last decade of effort without the support of our families, who had to put up with us working on the book through untold evenings, weekends, and even during many vacations. We hope that all of their patience and encouragement has paid off, and we thank them from the bottom of our hearts for sticking with us during the completion of this book.

—Wolfgang Bauer

Changes Since the Second Edition

In all chapters we added apps to perform interactive Concept Checks, a total number of 306, distributed over all 40 chapters.

Chapter 1

We added interactive apps to study logarithmic scales of length, mass, and time. We also provided interactive apps for vector addition, scalar vector products, and vector products in Cartesian and spherical coordinates. The definition of the kilogram base unit was updated.

Chapter 2

We added an interactive app to study logarithmic scales of speed, an app to illustrate the relationship between position, velocity, and acceleration, a video demonstration of weightlessness during free fall, two apps to illustrate motion with constant acceleration visualized with a moving car, and an app that shows the convergence of difference ratios to derivatives. We also added two Concept Checks.

Chapter 3

We added apps to illustrate projectile motion trajectories with and without a drag force, two gaming apps to study relative motion, and an app to study Cartesian velocity components during projectile motion. We include three video demonstrations of a basketball free throw, the independence of motion in the x- and y-directions, and the “shoot-the-monkey” lecture demonstration.

Chapter 4

We added two video demonstrations of dropping objects that reach terminal speed and on acceleration on an inclined plane. We supplied an app with which the student can study the Atwood machine, and we included seven different apps with which the student can practice drawing free-body diagrams. We added three new Concept Checks.

Chapter 5

We added interactive apps to study logarithmic scales of energy and power. We also included apps to study wind turbine power production, overall U.S. electricity production, visualization of the work done by gravity, and studying motion on an inclined plane during snowboarding. Video demonstrations included were lifting of a chain, lifting of a weight, and dropping of a vase. To introduce the spring force, we included an app to show the force vector and another app to portray the work done against the spring force. Figures 5.6 and 5.20 were updated with recent data, and the discussion of renewable electricity production was revised.

Chapter 6

We added video demonstrations for potential energy stored in deformation, for the potential energy of a waterfall, and for races between two identical balls on different paths. Apps illustrating the difference in work done by gravity and the friction force and for motion on an inclined plane with friction were also added. Three additional Concept Checks were included.

Chapter 7

We added video demonstrations for the ballistic pendulum, collision of a basketball and tennis ball, totally elastic air track collisions with equal and unequal masses, pendulum collisions, a pile driver, totally inelastic collisions, and collisions with two different coefficients of restitution. Apps to simulate totally elastic and totally inelastic collisions were provided. One additional Concept Check was included.

Chapter 8

Apps to illustrate vectors in cylindrical and spherical coordinate systems were provided. Two videos showing launches of toy rockets were included. Example 8.2 was revised. One additional Concept Check was inserted.

Chapter 9

We added centripetal force video illustrations for chips on a table, with and without banking, a roller-coaster loop, and a ball on circular motion in a vertical plane. We also provided a video of a wind turbine / wind farm. Two apps to illustrate polar coordinates were included, and four Concept Checks were added. Two examples referring to outdated technologies were removed.

Chapter 10

One Concept Check was added and another one removed. A total of 25 video demonstrations for the angular momentum chair, for angular momentum conservation, for torque, for a yo-yo, for rolling motion through a loop, for a gyroscope, for precession, for races between round objects with different moments of inertia, and for falling hinged rods were produced. We included an app to study the Atwood machine including the rotation of the pulley.

Chapter 11

Four different apps to practice drawing of free-body diagrams were added. A gaming app for stacking blocks was included as well.

Chapter 12

We revised Example 12.4, including Figure 12.21, with recent data on the black hole in the center of our galaxy, and discussed the Nobel Prize–winning work leading to the production of this figure. Example 12.5, which quantitatively discusses evidence for dark matter in the Andromeda galaxy was added. We updated Figure 12.23 with satellite positions as of December 2021. One additional Concept Check was inserted. We added apps to study Kepler's Laws, satellite orbits, and kinetic and potential energy in orbits. Videos illustrating planetary orbits in geo-centric and helio-centric frames were produced.

Chapter 13

We added interactive apps to study logarithmic scales of pressure. A total of 12 video demonstrations showing a wind farm, a swimmer in paint thinner and water, the Bernoulli Effect, buoyancy, and the effects of air pressure were produced. We also included an additional app to study the continuity equation.

Chapter 14

Apps to enable the student to study the similarities between circular motion and harmonic oscillations, pendulum motion, a mass on a spring in undamped harmonic motion, a mass on a spring in damped oscillation, and a mass on a spring with forced damped oscillations were added. Six video demonstrations of oscillating systems were produced.

Chapter 15

We produced 12 video demonstrations of coupled oscillations, wave propagation, wave addition, standing waves, and resonance. We also included apps to simulate and study eigenmodes in coupled oscillations, wave interference in one dimension and in two dimension. We updated Section 15.9 to reflect the advances made in gravitational wave detection.

Chapter 16

We inserted a new Concept Check. We included videos on wave tanks, resonance pipes, the Doppler effect, and beats. We also produced apps to enable the student to study beats, the Doppler effect, and the creation of Mach cones.

Chapter 17

We added interactive apps to study logarithmic scales of temperature. An app to illustrate temperature conversion was also included. We also produced video demonstrations of bimetal bending, as well as thermal expansion. Section 17.5, on the surface temperature of Earth, was updated with the most recent data. Section 17.6, on the temperature of the Universe, was updated with the most recent findings from the Planck observatory.

Chapter 18

We created a simple app to visualize different countries' contributions to the discovery of elements during the last few centuries. We also included apps to show the phase transition temperature of the individual elements, and the heat required to change the temperature of ice/water/steam. We updated the section on global warming and Figure 18.28 to reflect the most recent data on the CO_2 concentration in the atmosphere. A discussion of the 2021 Nobel Prize, awarded to Syukuro Manabe, was included.

Chapter 19

We included three video demonstrations of the thermal expansion and contraction of gases. Two apps on three-dimensional gases and gas law allow the student to study the behavior of gases at different temperatures, pressures, and volumes.

Chapter 20

We included video demonstrations of a heat pump and a Sterling engine. We also provided an app that allows the student to visualize the free expansion of a gas in three dimensions, and an app to study the Carnot process.

Chapter 21

We produced two video demonstrations of electrostatic attraction. We added an app that allows students to visualize the Coulomb interaction between point charges.

Chapter 22

We added video demonstrations of the Faraday cage, a visualization of a dipole field, and video demonstrations of electrostatic deflection, as well as shielding. We also included an app to let students study electric field in three dimensions.

Chapter 23

Two video demonstrations of a Van de Graaf generator are included. We also added an app to help the student visualize electric potential. A new Example 23.8 was added, and a new Conceptual Question 23.16 was constructed.

Chapter 24

We added two video demonstrations of capacitor discharges. We provided an app to allow the student to experiment with the equivalent capacitance of several configurations of individual capacitors in series and/or in parallel. We updated the discussion of the National Ignition Facility with the most recent performance data.

Chapter 25

We added an interactive app to study logarithmic scales of current. The video demonstrations added to this chapter are about drift velocity and on conduction in heated glass. We created two apps to enable the student to visualize the potential and currents in a circuit with resistors in parallel and in series. Another app allows the student to experiment with the equivalent resistance of several configurations of individual resistors in series and/or in parallel.

Chapter 26

We added a video showing the time dependence of the current in an RC circuit. Two apps allow the student to experiment with charging and discharging of capacitors in RC circuits. Another app lets the student change parameters in a multi-loop circuit of resistors and batteries to study Kirchhoff's rules. A figure discussing an EEG taken with an Apple Watch was added.

Page xxviii

Chapter 27

We added six video demonstrations that show magnetic forces on current-carrying wires and bending of electron beams in magnetic fields. We also included an app that allows the student to study and visualize the Lorentz force.

Chapter 28

New video demonstrations include torque on a compass needle, an electromagnet in action, forces between current-carrying wires, and the Curie temperature. We added an app to illustrate the definition of Ampere's Law.

Chapter 29

We added 12 video demonstrations on induction and eddy currents. A new induction app allows the student to explore induced currents in a loop due to moving magnets.

Chapter 30

We added three new apps that allow detailed visualization of RLC circuits, including frequency dependence of impedance and phasors.

Chapter 31

We updated the discussion of assigned frequency bands in the electromagnetic spectrum. We also updated Example 31.1 to reflect battery performance in modern electric cars. We added five new video demonstrations about polarization and radiation pressure. We included a new app on linear polarizers that allows the student to study polarized light.

Chapter 32

We added eight new apps to allow the student to interactively explore image construction with plane mirrors, parabolic mirrors, converging mirrors, diverging mirrors, dispersion in prisms, and Snell's Law.

Chapter 33

We added new apps for image construction with converging lenses and diverging lenses.

Chapter 34

One new video demonstration and four new apps allow detailed interactive exploration of diffraction.

Chapter 35

We rewrote the discussion of gravitational waves in Section 35.5 following their discovery in 2015, which led to the 2017 Nobel Prize in Physics. Video demonstrations for the equivalence principle and particle-antiparticle creation at RHIC are now included. We also added an app that interactively explores the twin paradox.

Chapter 36

We updated the discussion of cosmic microwave background with new results. The discussion of fundamental constants was updated to reflect the most recent changes in the standards. An app to explore blackbody radiation, Planck's Radiation Law, and Wien's Law was added.

Chapter 37

We added an app for the student to study energy levels and wave functions for a quantum particle in a box. We updated the discussion of quantum computing to reflect the most recent achievements.

Chapter 38

We updated the periodic table with the names of recently named elements 113, 115, 117, and 118. We updated the discussion of high-powered lasers with the newest performance data. Three new apps allow the student to explore the Bohr model of the atom, the quantum mechanical wave functions of the hydrogen atom, and the filling of electron shells in the periodic table.

Chapter 39

Additive and subtractive color mixer apps were added to illustrate the ideas behind quark and gluon confinement. Discussions of masses and lifetimes of elementary particles were updated to conform with the most recent research results. The Planck results replace the WMAP results for the measurements of the cosmic microwave background.

Chapter 40

We added video demonstrations for a chain reaction (with corks and mousetraps) and a heavy ion collision. New interactive apps allow the student to explore chain reactions, MRIs, and decays. Two additional apps that were added explore isotopes and their half-lives. We updated Figure 40.5 with the newly discovered isotopes.

The Big Picture

"All science is either physics or stamp collecting"

This quote is attributed to Ernest Rutherford (1871–1937), who received the Nobel Prize in *Chemistry* in 1908. What he meant by this is that there are two approaches to scientific inquiry. One is the collection of facts for which causal connections are not quite understood, and which need to be committed to memory, the "stamp collecting" method. The method of physics is that of conducting carefully controlled and reproducible measurements, and using those to arrive at universal laws, which can be used to predict other processes and phenomena. And this is the scientific method we are attempting to expose you to in this textbook.

Source: NASA, ESA, CSA, STScI

The language of physics is mathematics and statistics. Trigonometry and calculus, for example, were developed to aid in the description of mechanics phenomena. Sir Isaac Newton (1642–1727), perhaps the most famous scientist of all time, developed calculus to express the principles of mechanics. This intimate connection between mathematics and physics continues even today, for example, with string theory and topology. Modern particle physics experiments collect almost unimaginably large datasets and scientists often are forced to conduct needle-in-haystack types of analysis, which challenge what is considered to

be the state of the art in statistics. Through condensed matter experiments and theories researchers have even discovered new kinds of fractional statistics.

Most introductory physics textbooks focus on the expression of basic physics in the form of mathematical equations, which gives physics its predictive power. This book is no exception. But we also need to realize that physicists are using a second language to describe and predict the physical world and its complexity. This language is that of computing. Most physics research, from modeling the global climate to solving quantum chromodynamics on a lattice, would be impossible without the use of cutting-edge computing. For this reason, we recommend that you enroll in a computer programming language class as soon as possible.

Just like the interaction with mathematics and statistics, the intersection of physics and computer science is mutually beneficial, too. The invention of the transistor, the micro-processor, magnetic and the solid-state storage devices, fiber optics, and many other physics advances have revolutionized computers and computing in the last half century. And, of course, we want to mention that the World Wide Web was invented by Sir Tim Berners-Lee in 1989 at the CERN physics laboratory in Switzerland. Now quantum computing is promising to revolutionize computing and information processing yet again.

Physics, in the sense encapsuled by Rutherford's aforementioned quote, forms the basis for all other sciences and engineering disciplines. During the 20th century the convergence between chemistry and physics has been most impressive, and now the structure of most molecules and the reaction between many chemical compounds can be predicted and modeled from first principles. The 21st century will witness the same convergence between biology and physics. Nowhere has this been more impressively demonstrated than in the development of the mRNA vaccines, which allowed the world to emerge from the 2020 coronavirus pandemic, and in the invention of the CRISPR-Cas9 gene editing technique, which earned Jennifer Doudna and Emmanuelle Charpentier the Nobel Prize in Chemistry in 2020. Sequencing of the human genome, first completed in 2003 at a

cost of over a billion dollars, can now be done quickly for a few hundred dollars.

The same physical laws apply to the smallest constituents of matter and the overall structure of the entire universe. Particle physicists have been remarkably successful in developing a standard model of elementary particles and their interactions. In 1995, the sixth and last of the basic quarks, the top quark, was found in experiments conducted at Fermilab. And in 2012, the Higgs boson was found at CERN's Large Hadron Collider. This discovery concludes the search for all particles postulated by the standard model. But even deeper questions remain, and new theories, such as string theory or super-symmetric theories have been constructed and are under intense investigation. There are also strong indications that dark matter and dark energy exist, and that visible matter is only approximately one-quarter of the content of our universe. Several experiments that have started operations or are in the planning stages will hopefully give more definite answers in the next decade.

Quarks and gluons form protons and neutrons, and these in turn can assemble into atomic nuclei. More than 3000 of these isotopes of atomic nuclei have been discovered so far, with 10% of these discoveries being reported since the publication of the first edition of this textbook in 2012. Many of these isotopes have applications in medical imaging and treatment, as well as in engineering. And with each discovery of the approximately 6000 isotopes that are postulated to exist, we are getting closer to understanding how all matter around us came into existence.

These discoveries on the smallest scales are intimately connected to our understanding of the universe as a whole and how it was created in the Big Bang singularity approximately 13.8 billion years ago. Satellite-based telescopes like the formidable Hubble Space Telescope have opened views deeper into the universe than was ever before possible. The newest of these, the James Webb Space Telescope, was successfully launched at the

end of 2021 and was deployed at the L2 Lagrange Point, approximately 1.5 million kilometers from Earth. The biggest discovery in astrophysics, however, has been the direct detection of gravitational waves by the LIGO laboratory in Livingston, Louisiana, and in Hanford, Washington, in 2015, opening an entirely new view of the universe. The 2017 physics Nobel Prize was awarded to Rainer Weiss, Kip Thorne, and Barry Barish for their role in this discovery.

Since the beginning of the industrial age in the mid-18th century, humans have used fossil fuels for industrial production, heating, transportation, and electricity generation. The associated release of over a trillion tons of greenhouse gases into our atmosphere has caused global warming, which is approaching dangerous levels. Physicists have been at the forefront of developing reliable modeling of Earth's climate, quantifying variability, and reliably predicting global warming, for which Syukuro Manabe and Klaus Hasselmann shared the 2021 physics Nobel Prize.

Humanity needs to wean itself from fossil fuels and needs to become much better at not wasting energy in conversion processes. One shining example is the generation of light from electricity, which has become tremendously more efficient and cheaper with the invention of blue light-emitting diodes. Isamu Akasaki, Hiroshi Amano, and Shuji Nakamura were awarded the 2014 Nobel Prize in Physics for this relatively recent invention, which is also the basis for every modern smartphone display, computer screen, and flat-panel television.

Tremendous progress, fueled by physics discoveries, has also been made in the generation of renewable electricity. More efficient, cheaper, and longer-lasting solar cells, wind turbines that can work at lower wind speeds, better geothermal power plants, and hydro power storage plants with better cycle efficiency have made it possible to produce more than 10% of global electricity from renewable power sources. This is up from a minuscule fraction at the turn of the millennium, and this electricity is now cheaper than fossil fuel–generated power. Batteries are becoming 5 to 10% more efficient each year, and their price is falling as well. This is making the transportation

revolution in electric vehicles possible, which we are witnessing now.

Physics and related science and engineering disciplines drive all of this progress and enlightenment, with no end in sight. In this introduction we have picked only a few examples, and throughout this book you will find many more. We hope that you will utilize this textbook as your first step on your own successful route to exploration and discovery.

PART 1 MECHANICS OF POINT PARTICLES

1 Overview

WHAT WE WILL LEARN 4

1.1 Why Study Physics? 4

1.2 Working with Numbers 5
Scientific Notation 5
Significant Figures 5

1.3 SI Unit System 6
Example 1.1 Units of Land Area 9
Metrology: Research on Measures and Standards 9

1.4 The Scales of Our World 10
Length Scales 10
Mass Scales 11
Time Scales 11

1.5 General Problem-Solving Strategy 12
Solved Problem 1.1 Volume of a Cylinder 13
Example 1.2 Volume of a Barrel of Oil 14
Solved Problem 1.2 View from the Willis Tower 15
Problem-Solving Guidelines: Limits 16
Problem-Solving Guidelines: Ratios 17

Multi-Version Exercises 32

The dramatic image in Figure 1.1 could be showing any of several things: a colored liquid spreading out in a glass of water, or perhaps biological activity in some organism, or maybe even an artist's idea of mountains on some unknown planet. If we said the view was 70 wide, would that help you decide what the picture shows? Probably not—you need to know if we mean, for example, 70 meters or 70 millionths of an inch or 70 thousand miles.

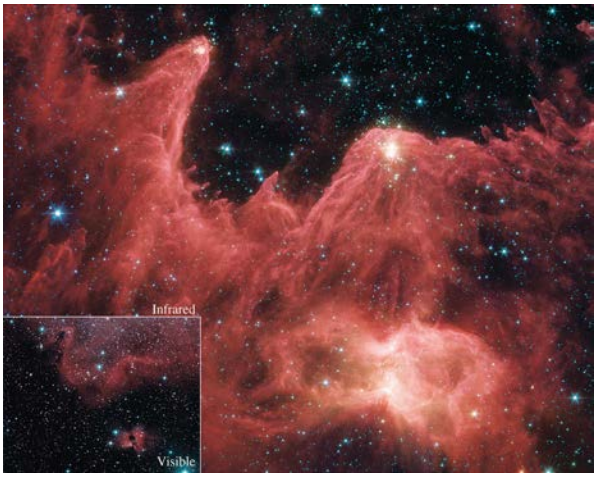

FIGURE 1.1 An image of the W5 star-forming region taken by the Spitzer Space Telescope using infrared light.

JPL-Caltech/L. Allen (Harvard Smithsonian CfA)/NASA

In fact, this infrared image taken by the Spitzer Space Telescope shows huge clouds of gas and dust about 70 light-years across. (A light-year is the distance traveled by light in 1 year, about 10 quadrillion meters.) These clouds are about 6500 light-years away from Earth and contain newly formed stars embedded in the glowing regions. The technology that enables us to see images such as this one is at the forefront of contemporary astronomy, but it depends in a real way on the basic ideas of numbers, units, and vectors presented in this chapter.

The ideas described in this chapter are not necessarily principles of physics, but they help us to formulate and communicate physical ideas and observations. We will use the concepts of units, scientific notation, significant figures, and vector quantities throughout the course. Once you have understood these concepts, we can go on to discuss physical descriptions of motion and its causes.

WHAT WE WILL LEARN

- The use of scientific notation and the appropriate number of significant figures is important in physics.
- We will become familiar with the international unit system and the definitions of the base units as well as methods of converting among other unit systems.
- We will use available length, mass, and time scales to establish reference points for grasping the vast diversity of systems in physics.
- We will apply a problem-solving strategy that will be useful in analyzing and understanding problems throughout this course and in science and engineering applications.
- We will work with vectors: vector addition and subtraction, multiplication of vectors, unit vectors, and length and direction of vectors.

1.1 Why Study Physics?

Perhaps your reason for studying physics can be quickly summed up as "Because it is required for my major!" While this motivation is certainly compelling, the study of science, and particularly physics, offers a few additional benefits.

Physics is the science on which all other natural and engineering sciences are built. All modern technological advances—from laser surgery to television, from computers to refrigerators, from cars to airplanes—trace back directly to basic physics. A good grasp of essential physics concepts gives you a solid foundation on which to construct advanced knowledge in all sciences. For example, the conservation laws and symmetry principles of physics also hold true for all scientific phenomena and many aspects of everyday life.

The study of physics will help you grasp the scales of distance, mass, and time, from the smallest constituents inside the nuclei of atoms to the galaxies that make up our universe. All natural systems follow the same basic laws of physics, providing a unifying concept for understanding how we fit into the overall scheme of the universe.

Physics is intimately connected with mathematics because it brings to life the abstract concepts used in trigonometry, algebra, and calculus. The analytical thinking and general techniques for problem solving that you learn here will remain useful for the rest of your life.

Science, especially physics, helps remove irrationality from our explanations of the world around us. Prescientific thinking resorted to mythology to explain natural phenomena. For example, the old Germanic tribes believed the god Thor using his hammer caused thunder. You may smile when you read this account, knowing that thunder and lightning come from electric discharges in the atmosphere. However, if you read the daily news, you will find that some misconceptions from prescientific thinking persist even today. You may not find the answer to the meaning of life in this course, but at the very least you will come away with some of the intellectual tools that enable you to weed out inconsistent, logically flawed theories and misconceptions that contradict experimentally verifiable facts. Scientific progress over the last millennium has provided a rational explanation for most of what occurs in the natural world surrounding us.

Through consistent theories and well-designed experiments, physics has helped us obtain a deeper understanding of our surroundings and has given us greater ability to control them. In a time when the consequences of air and water pollution, limited energy resources, and global warming threaten the continued existence of huge portions of life on Earth, the need to understand the results of our interactions with the environment has never been greater. Much of environmental science is based on fundamental physics, and physics drives much of the technology essential to progress in chemistry and the life sciences. You may well be called upon to help decide public policy in these areas, whether as a scientist, an engineer, or simply as a citizen. Having an objective understanding of basic scientific issues is of vital importance in making such decisions. Thus, you need to acquire scientific literacy, an essential tool for every citizen in our technology-driven society.

You cannot become scientifically literate without command of the necessary elementary tools, just as it is impossible to make music without the ability to play an instrument. This is the main purpose of this text: to properly equip you to make sound contributions to the important discussions and decisions of our time. You will emerge from reading and working with this text with a deeper appreciation for the fundamental laws that govern our universe and for the tools that humanity has developed to uncover them, tools that transcend cultures and historic eras.

1.2 Working with Numbers

Scientists have established logical rules to govern how they communicate quantitative information to one another. If you want to report the result of a measurement—for example, the distance between two cities, your own weight, or the length of a lecture—you have to specify this result in multiples of a standard unit. Thus, a measurement is the combination of a number and a unit.

At first thought, writing down numbers doesn't seem very difficult. However, in physics, we need to deal with two complications: how to deal with very big or very small numbers, and how to specify precision.

Scientific Notation

If you want to report a really big number, it becomes tedious to write it out. For example, the human body contains approximately 7,000,000,000,000,000,000,000,000,000 atoms. If you used this number often, you would surely like to have a more compact notation for it. This is exactly what **scientific notation** is. It represents a number as the product of a number greater than or equal to 1 and less than 10 (called the *mantissa*) and a power (or exponent) of 10:

$$\text{number} = \text{mantissa} \cdot 10^{\text{exponent}}. \qquad \textbf{(1.1)}$$

The number of atoms in the human body can thus be written compactly as $7 \cdot 10^{27}$, where 7 is the mantissa and 27 is the exponent.

Another advantage of scientific notation is that it makes it easy to multiply and divide large numbers. To multiply two numbers in scientific notation, we multiply their mantissas and then add their exponents. If we wanted to estimate, for example, how many atoms are contained in the bodies of all the people on Earth, we could do this calculation rather easily. Earth hosts approximately 7 billion (=$7 \cdot 10^9$) humans. All we have to do to find our answer is to multiply $7 \cdot 10^{27}$ by $7 \cdot 10^9$. We do this by multiplying the two mantissas and adding the exponents:

$$\left(7 \cdot 10^{27}\right) \cdot \left(7 \cdot 10^{9}\right) = (7 \cdot 7) \cdot 10^{27+9} = 49 \cdot 10^{36} = 4.9 \cdot 10^{37}. \qquad \textbf{(1.2)}$$

Concept Check 1.1

The total surface area of Earth is $A = 4\pi R^2 = 4\pi(6370\text{ km})^2 = 5.099.10^{14}$ m^2. Assuming there are 7.0 billion humans on the planet, what is the available surface area per person?

a) $7.3.10^4$ m^2

b) $7.3.10^{24}$ m^2

c) $3.6.10^{24}$ m^2

d) $3.6.10^4$ m^2

In the last step, we follow the common convention of keeping only one digit in front of the decimal point of the mantissa and adjusting the exponent accordingly. (But be advised that we will have to further adjust this answer—read on!)

Division with scientific notation is equally straightforward: If we want to calculate A / B, we divide the mantissa of A by the mantissa of B and subtract the exponent of B from the exponent of A.

Significant Figures

When we specified the number of atoms in the average human body as $7 \cdot 10^{27}$, we meant to indicate that we know it is at least $6.5 \cdot 10^{27}$ but smaller than $7.5 \cdot 10^{27}$. However, if we had written $7.0 \cdot 10^{27}$, we would have implied that we know the true number is somewhere between $6.95 \cdot 10^{27}$ and $7.05 \cdot 10^{27}$. This statement is more precise than the previous statement.

As a general rule, the number of digits you write in the mantissa specifies how precisely you claim to know it. The more digits specified, the more precision is implied (see Figure 1.2). We call the number of digits in the mantissa the number of **significant figures**. Here are some rules about using significant figures followed in each case by an example:

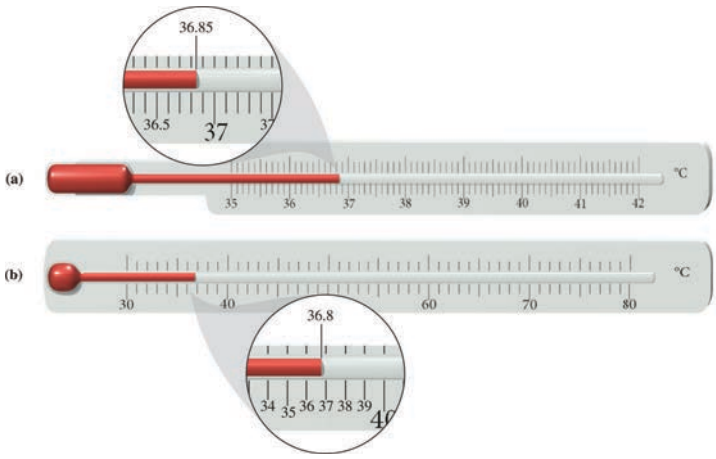

FIGURE 1.2 Two thermometers measuring the same temperature. (a) The thermometer is marked in tenths of a degree and can be read to four significant figures (36.85 $^{\circ}$C); (b) the thermometer is marked in degrees, so it can be read to only three significant figures (36.8 $^{\circ}$C).

- The number of significant figures is the number of reliably known digits. For example, 1.62 has three significant figures; 1.6 has two significant figures.
- If you give a number as an integer, you specify it with infinite precision. For example, if someone says that he or she has 3 children, this means exactly 3, no less and no more.

Concept Check 1.2

How many significant figures are in each of the following numbers?

a) 2.150

b) 0.000215

c) 215.00

d) 0.215000

e) 0.215 + 0.21

- Leading zeros do not count as significant digits. The number 1.62 has the same number of significant digits as 0.00162. There are three significant figures in both numbers. We start counting significant digits from the left at the first nonzero digit.
- Trailing zeros, on the other hand, do count as significant digits. The number 1.620 has four significant figures. Writing a trailing zero implies greater precision!
- Numbers in scientific notation have as many significant figures as their mantissa. For example, the number $9.11 \cdot 10^{-31}$ has three significant figures because that's what the mantissa (9.11) has. The size of the exponent has no influence.
- You can never have more significant figures in a result than you start with in any of the factors of a multiplication or division. For example, 1.23 / 3.4461 is not equal to 0.3569252. Your calculator may give you that answer, but calculators do not automatically display the correct number of significant figures. Correctly, 1.23 / 3.4461 = 0.357. You must round a calculator result to the proper number of significant figures—in this case, three, which is the number of significant figures in the numerator.
- You can only add or subtract when there are significant figures for that place in every number. For example, 1.23 + 3.4461 = 4.68, and not 4.6761 as you may think. This rule, in particular, requires some getting used to.

Concept Check 1.3

For the two numbers $x = 0.43$ and $y = 3.53$, which of the following has the greatest number of significant figures?

a) the sum, $x + y$

b) the product, $x\,y$

c) the difference, $x - y$

d) the number x

e) the number y

To finish this discussion of significant figures, let's reconsider the total number of atoms contained in the bodies of all people on Earth. We started with two quantities that were given to only one significant figure. Therefore, the result of our multiplication needs to be properly rounded to one significant digit. The combined number of atoms in all human bodies is thus correctly stated as $5. \cdot 10^{37}$.

1.3 SI Unit System

In high school, you may have been introduced to the international system of units and compared it to the British system of units in common use in the United States. You may have driven on a freeway on which the distances are posted both in miles and in kilometers or purchased food where the price was quoted per pound and per kilogram.

The international system of units is often abbreviated as SI (for Système International). Sometimes the units in this system are called *metric units*. The **SI unit system** is the standard used for scientific work around the world. The seven base units for the SI system are given in Table 1.1.

Table 1.1 Unit Names and Abbreviations for the Base Units of the SI System of Units

Unit	Abbreviation	Base Unit for
meter	m	length
kilogram	kg	mass
second	s	time
ampere	A	current
kelvin	K	temperature
mole	mol	amount of a substance
candela	cd	luminous intensity

The first letters of the first four base units provide another commonly used name for the SI system: the MKSA system. We will only use the first three units (meter, kilogram, and second) in the entire first part of this book and in all of mechanics. The current definitions of these base units are as follows:

- 1 meter (m) is the distance that a light beam in vacuum travels in 1/299,792,458 of a second. Originally, the meter was related to the size of the Earth (Figure 1.3).

FIGURE 1.3 Originally, the meter was defined as 1 ten-millionth of the length of the meridian through Paris from the North Pole to the Equator.

Stockbyte/Getty Images

- As of May 20, 2019, the kilogram (kg) is defined using a fixed value for the Planck constant and the definition of the meter and second, which are based on constants. Previously, the kilogram had been defined since 1889 as the mass of the international prototype of the kilogram. This prototype, shown in its elaborate storage container in Figure 1.4, is kept just outside Paris, France, under carefully controlled environmental conditions.

FIGURE 1.4 Prototype of the kilogram, stored near Paris, France.

Benoit Tessier/REUTERS/Alamy Stock Photo

- 1 second (s) is the time interval during which 9,192,631,770 oscillations of the electromagnetic wave (see Chapter 31) that corresponds to the transition between two specific states of the cesium-133 atom. Until 1967, the standard for the second was 1/86,400 of a mean solar day. However, the atomic definition is more precise and more reliably reproducible.

Notation Convention: It is common practice to use roman letters for unit abbreviations and italic letters for physical quantities. We follow this convention in this book. For example, m stands for the unit meter, while m is used for the physical quantity mass. Thus, the expression $m = 17.2$ kg specifies that the mass of an object is 17.2 kilograms.

Units for all other physical quantities can be derived from the seven base units of Table 1.1. The unit for area, for example, is m^2. The units for volume and mass density are m^3 and kg/m^2, respectively. The units for velocity and acceleration are m/s and m/s^2, respectively. Some derived units were used so often that it became convenient to give them their own names and symbols. Often the name is that of a famous physicist. Table 1.2 lists the 20 derived SI units with special names. In the two rightmost columns of the table, the named unit is listed in terms of other named units and then in terms of SI base units. Also included in this table are the radian and steradian, the dimensionless units of angle and solid angle, respectively.

Table 1.2 Common SI Derived Units

Derived or Dimensionless Unit	Name	Symbol	Equivalent	Expressions
Absorbed dose	gray	Gy	J/kg	$m^2 s^{-2}$
Angle	radian	rad	—	—
Capacitance	farad	F	C/V	$m^{-2} kg^{-1} s^4 A^2$
Catalytic activity	katal	kat	—	s^{-1} mol
Dose equivalent	sievert	Sv	J/kg	$m^2 s^{-2}$
Electric charge	coulomb	C	—	s A
Electric conductance	siemens	S	A/V	$m^{-2} kg^{-1} s^3 A^2$
Electric potential	volt	V	W/A	m^2 kg s^{-3} A^{-1}
Electric resistance	ohm	Ω	V/A	m^2 kg s^{-3} A^{-2}
Energy	joule	J	N m	m^2 kg s^{-2}
Force	newton	N	—	m kg s^{-2}
Frequency	hertz	Hz	—	s^{-1}
Illuminance	lux	lx	lm/m^2	m^{-2} cd
Inductance	henry	H	Wb/A	m^2 kg s^{-2} A^{-2}
Luminous flux	lumen	lm	cd sr	cd
Magnetic flux	weber	Wb	V s	m^2 kg s^{-2} A^{-1}
Magnetic field	tesla	T	Wb/m^2	kg s^{-2} A^{-1}
Power	watt	W	J/s	m^2 kg s^{-3}
Pressure	pascal	Pa	N/m^2	m^{-1} kg s^{-2}
Radioactivity	becquerel	Bq	—	s^{-1}
Solid angle	steradian	sr	—	—
Temperature	degree Celsius	°C	—	K

You can obtain SI-recognized multiples of the base units and derived units by multiplying them by various factors of 10. These factors have universally accepted letter abbreviations that are used as prefixes, shown in Table 1.3. The use of standard prefixes (factors of 10) makes it easy to determine, for example, how many centimeters (cm) are in a kilometer (km):

$$1\text{km} = 10^3\text{m} = 10^3\text{m} \cdot \left(10^2 \text{ cm}/\text{m}\right) = 10^5 \text{ cm}. \tag{1.3}$$

Table 1.3 SI Standard Prefixes

Factor	Prefix	Symbol	Factor	Prefix	Symbol
10^{24}	yotta-	Y	10^{-24}	yocto-	y
10^{21}	zetta-	Z	10^{-21}	zepto-	z
10^{18}	exa-	E	10^{-18}	atto-	a
10^{15}	peta-	P	10^{-15}	femto-	f
10^{12}	tera-	T	10^{-12}	pico-	p
10^{9}	giga-	G	10^{-9}	nano-	n
10^{6}	mega-	M	10^{-6}	micro-	μ
10^{3}	kilo-	k	10^{-3}	milli-	m
10^{2}	hecto-	h	10^{-2}	centi-	c
10^{1}	deka-	da	10^{-1}	deci-	d

In comparison, note how tedious it is to figure out how many inches are in a mile:

$$1 \text{ mile}(5,280 \text{ feet} / \text{mile}) \cdot (12 \text{ inches} / \text{foot}) = 63,360 \text{ inches}. \tag{1.4}$$

As you can see, not only do you have to memorize particular conversion factors in the British system, but calculations also become more complicated. For calculations in the SI system, you only have to know the standard prefixes shown in Table 1.3 and how to add or subtract integers in the powers of 10.

The international system of units was adopted by France in 1799 and is now used daily in almost all countries of the world, the one notable exception being the United States. In the United States, we buy milk and gasoline in gallons, not in liters. Our cars show speed in miles per hour, not meters per second. When we go to the lumberyard, we buy wood as two-by-fours (actually 1.5 inches by 3.5 inches, but that's a different story). Since we use British units in our daily lives, this book will indicate British units where appropriate, to establish connections with everyday experiences. But we will use the SI unit system in all calculations to avoid having to work with the British unit conversion factors. However, we will sometimes provide equivalents in British units. This is a compromise that will be necessary only until the United States decides to adopt SI units as well.

The use of British units can be costly. The cost can range from a small expense, such as that incurred by car mechanics who need to purchase two sets of wrench socket sets, one metric and one British, to the very expensive loss of the *Mars Climate Orbiter* spacecraft (Figure 1.5) in September 1999. The crash of this spacecraft has been blamed on the fact that one of the engineering teams used British units and the other one SI units. The two teams relied on each other's numbers, without realizing that the units were not the same.

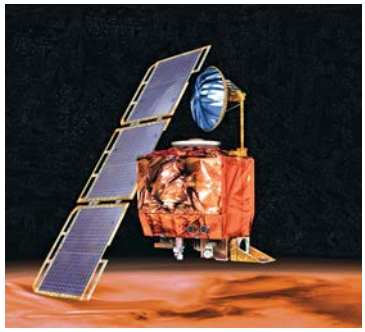

FIGURE 1.5 The *Mars Climate Orbiter*, a victim of faulty unit conversion.

JPL-Caltech/NASA

The use of powers of 10 is not completely consistent even within the SI system itself. The notable exception is in the time units, which are not factors of 10 times the base unit (second):

- 365 days form a year,
- a day has 24 hours,
- an hour contains 60 minutes, and
- a minute consists of 60 seconds.

Early metric pioneers tried to establish a completely consistent set of metric time units, but these attempts failed. The not-exactly-metric nature of time units extends to some derived units. For example, a European sedan's speedometer does not show speeds in meters per second, but in kilometers per hour.

EXAMPLE 1.1 Units of Land Area

The unit of land area used in countries that use the SI system is the hectare, defined as $10,000\ \text{m}^2$. In the United States, land area is given in acres; an acre is defined as $43,560\ \text{ft}^2$.

PROBLEM

You just bought a plot of land with dimensions 2.00 km by 4.00 km. What is the area of your new purchase in hectares and acres?

SOLUTION

The area A is given by

$$A = \text{length} \cdot \text{width} = (2.00\,\text{km})(4.00\,\text{km}) = \left(2.00 \cdot 10^3\text{m}\right)\left(4.00 \cdot 10^3\text{m}\right)$$
$$A = 8.00\,\text{km}^2 = 8.00 \cdot 10^6\text{m}^2.$$

The area of this plot of land in hectares is then

$$\text{A} = 8.00 \cdot 10^6\ \text{m}^2\ \frac{1\ \text{hectare}}{10,000\ \text{m}^2} = 8.00 \cdot 10^2\ \text{hectares} = 800.\ \text{hectares}.$$

To find the area of the land in acres, we need the length and width in British units:

$$\text{length} = 2.00\ \text{km}\ \frac{1\ \text{mi}}{1.609\ \text{km}} = 1.24\ \text{mi}\frac{5280\ \text{ft}}{1\ \text{mi}} = 6563\ \text{ft}$$
$$\text{width} = 4.00\ \text{km}\ \frac{1\ \text{mi}}{1.609\ \text{km}} = 2.49\ \text{mi}\frac{5280\ \text{ft}}{1\ \text{mi}} = 13{,}130\ \text{ft}.$$

The area is then

$$A = \text{length} \cdot \text{width} = (1.24\,\text{mi})(2.49\,\text{mi}) = (6563\,\text{ft})(13,130\,\text{ft})$$
$$A = 3.09\,\text{mi}^2 = 8.61 \cdot 10^7\,\text{ft}^2.$$

In acres, this is

$$A = 8.61 \cdot 10^7\,\text{ft}^2\ \frac{1\ \text{acre}}{43,560\,\text{ft}^2} = 1980\ \text{acres}.$$

Metrology: Research on Measures and Standards

The work of defining the standards for the base units of the SI system is by no means complete. A great deal of research is devoted to refining measurement technologies and pushing them to greater precision. This field of research is called **metrology**. In the United States, the laboratory that has the primary responsibility for this work is the National Institute of Standards and Technology (NIST). NIST works in collaboration with similar institutes in other countries to refine accepted standards for the SI base units.

The world's most accurate clock is currently an optical lattice clock that uses lasers to trap and cool strontium atoms and uses oscillations of the strontium atoms to keep time. The clock is accurate to 1 second in 15 billion years. This clock is so accurate that time is observed to pass more slowly when it is moved a few centimeters closer to the surface of the Earth in accordance with the predictions of general relativity (see Chapter 35). The clock was developed independently by Jun Ye and Hidetoshi Katori, for which they were awarded the 2022 Breakthrough Prize in Fundamental Physics. The clock developed in Jun Ye's laboratory is shown in Figure 1.6.

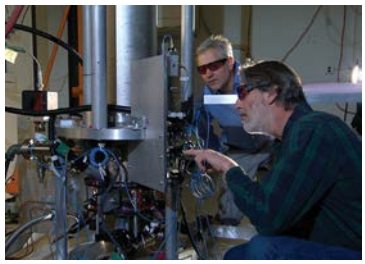

FIGURE 1.6 The optical lattice clock that is currently the world's most accurate clock located at the University of Colorado.

National Institute of Standards and Technology (NIST)

Greater precision in timekeeping is needed for many applications in our information-based society, where signals can travel around the world in less than 0.2 second. The Global Positioning System (GPS) is one example of technology that would be impossible to realize without the precision of atomic clocks and the physics research that enters into their construction. The GPS system also relies on Einstein's theory of relativity, which we will study in Chapter 35.

The International Committee for Weights and Measures approved a redefinition of the SI base units in November 2018 that defined the kilogram by adopting the value of Planck's constant to be exactly $h = 6.62607015 \cdot 10^{-34}\ \mathrm{kg \cdot m^2 \cdot s^{-1}}$, which defines the kilogram in terms of the second and the meter. The new definition took effect worldwide on May 20, 2019.

1.4 The Scales of Our World

The most amazing fact about physics is that its laws govern every object, from the smallest to the largest. The scales of the systems for which physics holds predictive power span many orders of magnitude (powers of 10), as we'll see in this section.

Nomenclature: In the following, you will read "on the order of" several times. This phrase means "within a factor of 2 or 3."

Length Scales

Length is defined as the distance measurement between two points in space. Figure 1.7 shows some length scales for common objects and systems that span over 40 orders of magnitude.

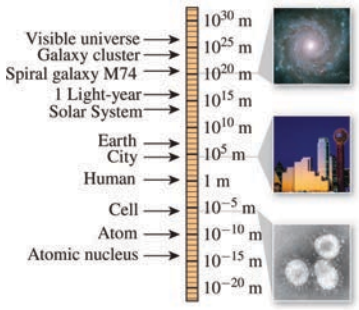

FIGURE 1.7 Range of length scales for physical systems. The pictures top to bottom are the spiral galaxy M74, the Dallas skyline, and the SARS virus.

(Galaxy M74): Gemini Observatory; **(Skyline):** Jacobs Stock Photography/Getty Images; **(SARS virus):** Dr. Fred Murphy, 1975, Centers for Disease Control and Prevention

Let's start with ourselves. On average, in the United States, a woman is 1.62 m (5 ft 4 in) tall, and a man measures 1.75 m (5 ft 9 in). Thus, human height is on the order of a meter. If you reduce the length scale for a human body by a factor of a million, you arrive at a micrometer. This is the typical diameter of a cell in your body or a bacterium.

If you reduce the length of your measuring stick by another factor of 10,000, you are at a scale of 10^{-10} m, the typical diameter of an individual atom. This is the smallest size we can resolve with the aid of the most advanced microscopes.

Inside the atom is its nucleus, with a diameter about 1/10,000 that of the atom, on the order of 10^{-14} m. The individual protons and neutrons that make up the atomic nucleus have a diameter of approximately 10^{-15} m $= 1$ fm (a femtometer).

Considering objects larger than ourselves, we can look at the scale of a typical city, on the order of kilometers. The diameter of Earth is just a little bigger than 10,000 km (12,760 km, to be more precise). As discussed earlier, the definition of the meter is now stated in terms of the speed of light. However, the meter was originally defined as 1 ten-millionth of the length of the meridian through Paris from the North Pole to the Equator. If a quarter circle has an arc length of 10 million meters (= 10,000 km), then the circumference of the entire circle would be exactly 40,000 km. Using the modern definition of the meter, the equatorial circumference of the Earth is 40,075 km, and the circumference along the meridian is 40,008 km.

The distance from the Earth to the Moon is 384,000 km, and the distance from the Earth to the Sun is greater by a factor of approximately 400, or about 150 million km. This distance is called an *astronomical unit* and has the symbol AU. Astronomers used this unit before the distance from Earth to Sun became known with accuracy, but it is still convenient today. In SI units, an astronomical unit is

$$1 \text{ AU} = 1.495 \ \ 98 \cdot 10^{11} \text{ m}. \tag{1.5}$$

The diameter of our Solar System is conventionally stated as approximately 10^{13} m, or 60 AU.

We have already remarked that light travels in a vacuum at a speed of approximately 300,000 km/s. Therefore, the distance between Earth and Moon is covered by light in just over 1 second, and light from the Sun takes approximately 8 minutes to reach Earth. In order to cover distance scales outside our Solar System, astronomers have introduced the (non-SI, but handy) unit of the light-year, the distance that light travels in 1 year in vacuum:

$$1 \text{ light-year} = 9.46 \cdot 10^{15} \text{ m}. \tag{1.6}$$

The nearest star to our Sun is just over 4 light-years away. The Andromeda Galaxy, the sister galaxy of our Milky Way, is about 2.5 million light-years $= 2 \cdot 10^{22}$ m away.

Finally, the radius of the visible universe is approximately 14 billion light-years $= 1.5 \cdot 10^{26}$ m. Thus, about 41 orders of magnitude span between the size of an individual proton and that of the entire visible universe.

Mass Scales

Mass is the amount of matter in an object. When you consider the range of masses of physical objects, you obtain an even more awesome span of orders of magnitude (Figure 1.8) than for lengths.

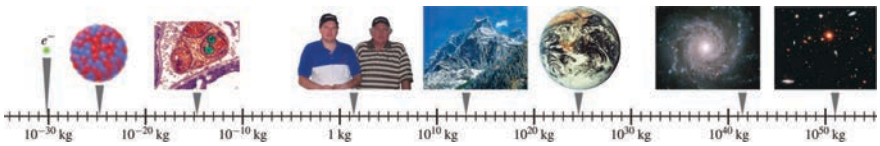

FIGURE 1.8 Range of mass scales for physical systems.

(TEM): Callista Images/Cultura Creative/Alamy Stock Photo; **(Authors):** W. Bauer and G. D. Westfall; **(Mountain):** Pixtal/AGE Fotostock; **(Earth):** Stockbyte/Getty Images; **(Galaxy M74):** Gemini Observatory; **(Universe):** NASA, ESA, and The Hubble Heritage Team (STScI/AURA)/Hubble Space Telescope ACS/STScI-PRC05-20

Atoms and their parts have incredibly small masses. The mass of an electron is only $9.11 \cdot 10^{-31}$ kg. A proton's mass is $1.67 \cdot 10^{-27}$ kg, roughly a factor of 2000 more than the mass of an electron. An individual atom of lead has a mass of $3.46 \cdot 10^{-25}$ kg.

The mass of a single cell in the human body is on the order of 10^{-13} kg to 10^{-12} kg. Even a fly has more than 100 million times the mass of a cell, at approximately 10^{-4} kg.

A car's mass is on the order of 10^{3} kg, and that of a passenger plane is on the order of 10^{5} kg.

A mountain typically has a mass of 10^{12} kg to 10^{14} kg, and the combined mass of all the water in all of the Earth's oceans is estimated to be on the order of 10^{21} kg.

The mass of the entire Earth can be specified fairly precisely at $6.0 \cdot 10^{24}$ kg. The Sun has a mass of $2.0 \cdot 10^{30}$ kg, or about 300,000 times the mass of the Earth. Our entire galaxy, the Milky Way, is estimated to have 200 billion stars in it and thus has a mass around $3 \cdot 10^{41}$ kg. Finally, the entire universe contains billions of galaxies. Depending on the assumptions about dark matter, a currently active research topic (see Chapter 12), the mass of the universe as a whole is roughly 10^{51} kg. However, you should recognize that this number is an estimate and may be off by a factor of up to 100.

Interestingly, some objects have no mass. For example, photons, the "particles" that light is made of, have zero mass.

Time Scales

Time is the duration between two events. Human time scales lie in the range from a second (the typical duration of a human heartbeat) to a century (about the life expectancy of a person born now). Incidentally, human life expectancy is increasing at an ever faster rate. During the Roman Empire, 2000 years ago, a person could expect to live only 25 years. In 1850, actuary tables listed the mean lifetime of a human as 39 years. Now that number is 80 years. Thus, it took almost 2000 years to add 50% to human life expectancy, but in the last 150 years, life expectancy has doubled again. This is perhaps the most direct evidence that science has basic benefits for all of us. Physics contributes to this progress by aiding the development of more sophisticated medical imaging and treatment equipment, and today's fundamental research will enter clinical practice tomorrow. Laser surgery, cancer radiation therapy, magnetic resonance imaging, and positron emission tomography are just a few examples of technological advances that have helped increase life expectancy.

In their research, the authors of this book study ultrarelativistic heavy-ion collisions. These collisions occur during time intervals on the order of 10^{-22} s, more than a million times shorter than the time intervals we can measure directly. During this course, you will learn that the time scale for the oscillation of visible light is 10^{-15} s, and that of audible sound is 10^{-3} s.

The longest time span we can measure *indirectly* or *infer* is the age of the universe. Current research puts this number at 13.8 billion years, with an uncertainty of 0.04 billion years.

We cannot leave this topic without mentioning one interesting fact to ponder during your next class lecture. Lectures typically last 50 minutes at most universities. A century, by comparison, has $100 \cdot 365 \cdot 24 \cdot 60 \approx 50{,}000{,}000$ minutes. So a lecture lasts about 1 millionth of a century, leading to a handy (non-SI) time unit, the microcentury = duration of one lecture.

1.5 General Problem-Solving Strategy

Physics involves more than solving problems—but problem solving is a big part of it. At times, while you are laboring over your homework assignments, it may seem that's all you do. However, repetition and practice are important parts of learning.

A basketball player spends hours practicing the fundamentals of free throw shooting. Many repetitions of the same action enable a player to become very reliable at this task. You need to develop the same philosophy toward solving mathematics and physics problems: You have to practice good problem-solving techniques. This work will pay huge dividends, not just during the remainder of this physics course, not just during exams, not even just in your other science classes, but also throughout your entire career.

What constitutes a good problem-solving strategy? Everybody develops his or her own routines, procedures, and shortcuts. However, here is a general blueprint that should help get you started:

1. **THINK** Read the problem carefully. Ask yourself what quantities are known, what quantities might be useful but are unknown, and what quantities are asked for in the solution. Write down these quantities and represent them with their commonly used symbols. Convert into SI units, if necessary.
2. **SKETCH** Make a sketch of the physical situation to help you visualize the problem. For many learning styles, a visual or graphical representation is essential, and it is often essential for defining the variables.
3. **RESEARCH** Write down the physical principles or laws that apply to the problem. Use equations representing these principles to connect the known and unknown quantities to each other. In some cases, you will immediately see an equation that has only the quantities that you know and the one unknown that you are supposed to calculate, and nothing else. More often you may have to do a bit of deriving, combining two or more known equations into the one that you need. This requires some experience, more than any of the other steps listed here. To the beginner, the task of deriving a new equation may look daunting, but you will get better at it the more you practice.
4. **SIMPLIFY** Do not plug numbers into your equation yet! Instead, simplify your result algebraically as much as possible. For example, if your result is expressed as a ratio, cancel out common factors in the numerator and the denominator. This step is particularly helpful if you need to calculate more than one quantity.
5. **CALCULATE** Put the numbers with units into the equation and get to work with a calculator. Typically, you will obtain a number and a physical unit as your answer.
6. **ROUND** Determine the number of significant figures that you want to have in your result. As a rule of thumb, a result obtained by multiplying or dividing should be rounded to the same number of significant figures as in the input quantity that is given with the least number of significant figures. You should not round in intermediate steps, as rounding too early might give you a wrong solution.

7. **DOUBLE-CHECK** Step back and look at the result. Judge for yourself if the answer (both the number and the units) seems realistic. You can often avoid handing in a wrong solution by making this final check. Sometimes the units of your answer are

simply wrong, and you know you must have made an error. Or sometimes the order of magnitude comes out totally wrong. For example, if your task is to calculate the mass of the Sun (we will do this later in this book), and your answer comes out near $10^6\ \mathrm{kg}$ (only a few thousand tons), you know you must have made a mistake somewhere.

Let's put this strategy to work in the following example.

SOLVED PROBLEM 1.1 Volume of a Cylinder

PROBLEM

Nuclear waste material in a physics laboratory is stored in a cylinder of height $4\frac{13}{16}$ inches and circumference $8\frac{3}{16}$ inches. What is the volume of this cylinder, measured in metric units?

SOLUTION

In order to practice problem-solving skills, we will go through each of the steps of the strategy outlined above.

THINK

From the question, we know that the height of the cylinder, converted to centimeters, is

$$\begin{aligned} h &= 4\tfrac{13}{16}\text{in} = 4.8125\ \text{in} \\ &= (4.8125\ \text{in}) \cdot (2.54\ \text{cm/in}) \\ &= 12.22375\ \text{cm}. \end{aligned}$$

Also, the circumference of the cylinder is specified as

$$\begin{aligned} c &= 8\tfrac{3}{16}\text{in} = 8.1875\ \text{in} \\ &= (8.1875\ \text{in}) \cdot (2.54\ \text{cm/in}) \\ &= 20.79625\ \text{cm}. \end{aligned}$$

Even though it is clear that the number of significant digits in our SI-converted values for h and c are clearly too high, we keep them for our intermediate calculations, and we only round our final answer to the proper number of significant digits.

SKETCH

Next, we produce a sketch, something like Figure 1.9. Note that the given quantities are shown with their symbolic representations, not with their numerical values. The circumference is represented by the thicker circle (oval, actually, in this projection).

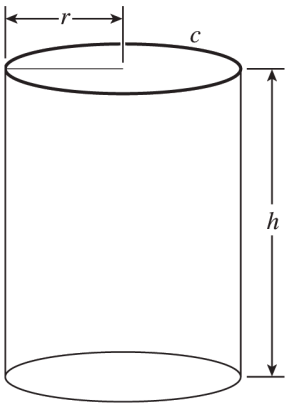

FIGURE 1.9 Sketch of right cylinder.

RESEARCH

Now we have to find the volume of the cylinder in terms of its height and its circumference. This relationship is not commonly listed in collections of geometric formulas. Instead, the volume of a cylinder is given as the product of base area and height:

$$V = \pi r^2 h.$$

Once we find a way to connect the radius and the circumference, we'll have the formula we need. The top and bottom areas of a cylinder are circles, and for a circle we know that

$$c = 2\pi r.$$

SIMPLIFY

Remember: We do not plug in numbers yet! To simplify our numerical task, we can solve the second equation for r and insert this result into the first equation:

$$c = 2\,\pi r \Rightarrow r = \frac{c}{2\pi}$$
$$v = \pi r^2 h = \pi\left(\frac{c}{2\pi}\right)^2 h = \frac{c^2 h}{4\pi}.$$

CALCULATE

Now it's time to get out the calculator and put in the numbers:

$$\begin{aligned} V &= \frac{c^2 h}{4\pi} \\ &= \frac{(20.79625\,\text{cm})^2 \cdot (12.22375\,\text{cm})}{4\pi} \\ &= 420.69239\,\text{cm}^3. \end{aligned}$$

ROUND

The output of the calculator has again made our result look much more precise than we can claim realistically. We need to round. Since the input quantities are given to only three significant figures, our result needs to be rounded to three significant figures. Our final answer is $V = 421.\,\text{cm}^3$.

DOUBLE-CHECK

Our last step is to check that the answer is reasonable. First, we look at the unit we got for our result. Cubic centimeters are a unit for volume, so our result passes its first test. Now let's look at the magnitude of our result. You might recognize that the height and circumference given for the cylinder are close to the corresponding dimensions of a soda can. If you look on a can of your favorite soft drink, it will list the contents as 12 fluid ounces and also give you the information that this is 355 mL. Because $1\,\text{mL} = 1\,\text{cm}^3$, our answer is reasonably close to the volume of the soda can. Note that this does *not* tell us that our calculation is correct, but it shows that we are not way off.

Suppose the researchers decide that a soda can is not large enough for holding the waste in the lab and replace it with a larger cylindrical container with a height of 44.6 cm and a circumference of 62.5 cm. If we want to calculate the volume of this replacement cylinder, we don't need to do all of Solved Problem 1.1 over again. Instead, we can go directly to the algebraic formula we derived in the Simplify step and substitute our new data into that, ending up with a volume of $13,900\ \text{cm}^3$ when rounded to three significant figures. This example illustrates the value of waiting to substitute in numbers until algebraic simplification has been completed.

In Solved Problem 1.1, you can see that we followed the seven steps outlined in our general strategy. It is tremendously helpful to train your brain to follow a certain procedure in attacking all kinds of problems. This is not unlike following the same routine whenever you are shooting free throws in basketball, where frequent repetition helps you build the muscle memory essential for consistent success, even when the game is on the line.

Perhaps more than anything, an introductory physics class should enable you to develop methods to come up with your own solutions to a variety of problems, eliminating the need to accept "authoritative" answers uncritically. The method we used in Solved Problem 1.1 is extremely useful, and we will practice it again and again in this book. However, to make a simple point, one that does not require the full set of steps used for a solved problem, we'll sometimes use an illustrative example.

EXAMPLE 1.2 Volume of a Barrel of Oil

PROBLEM

The volume of a barrel of oil is 159 L. We need to design a cylindrical container that will hold this volume of oil. The container needs to have a height of 1.00 m to fit in a transportation container. What is the required circumference of the cylindrical container?

SOLUTION

Starting with the equation we derived in the Simplify step in Solved Problem 1.1, we can relate the circumference, c, and the height, h, of the container to the volume, V, of the container:

$$V = \frac{c^2 h}{4\pi}.$$

Solving for the circumference, we get

$$c = \sqrt{\frac{4\pi V}{h}}.$$

The volume in SI units is

$$V = 159\ \text{L}\frac{1000\ \text{mL}}{\text{L}}\frac{1\ \text{cm}^3}{1\ \text{mL}}\frac{1\ \text{m}^3}{10^6\ \text{cm}^3} = 0.159\ \text{m}^3.$$

The required circumference is then

$$c = \sqrt{\frac{4\pi V}{h}} = \sqrt{\frac{4\pi(0.159\ \text{m}^3)}{1.00\ \text{m}}} = 1.41\ \text{m}.$$

As you may have already realized from the preceding problem and example, a good command of algebra is essential for success in an introductory physics class. For engineers and scientists, most universities and colleges also require calculus, but at many schools an introductory physics class and a calculus class can be taken concurrently. This first chapter does not contain any calculus, and subsequent chapters will review the relevant calculus concepts as you need them. However, there is another field of mathematics that is used extensively in introductory physics: trigonometry. Virtually every chapter of this book uses right triangles in some way. Therefore, it is a good idea to review the formulas for sine, cosine, and the like, as well as the indispensable Pythagorean Theorem. Let's look at another solved problem, which makes use of trigonometric concepts.

SOLVED PROBLEM 1.2 View from the Willis Tower

PROBLEM

It goes without saying that one can see farther from a tower than from ground level; the higher the tower, the farther one can see. The Willis Tower (formerly named Sears Tower) in Chicago has an observation deck, which is 412 m above ground. How far can one see out over Lake Michigan from this observation deck under perfect weather conditions? (Assume eye level is at 413 m above the level of the lake.)

SOLUTION

THINK

As we have stressed before, this is the most important step in the problem-solving process. A little preparation at this stage can save a lot of work at a later stage. Perfect weather conditions are specified, so fog or haze is not a limiting factor. What else could determine how far one can see? If the air is clear, one can see mountains that are quite far away. Why mountains? Because they are very tall. But the landscape around Chicago is flat. What then could limit the viewing range? Nothing, really; one can see all the way to the horizon. And what is the deciding factor for where the horizon is? It is the curvature of the Earth. Let's make a sketch to make this a little clearer.

SKETCH

Our sketch does not have to be elaborate, but it needs to show a simple version of the Willis Tower on the surface of the Earth. It is not important that the sketch be to scale, and we elect to greatly exaggerate the height of the tower relative to the size of the Earth. See Figure 1.10.

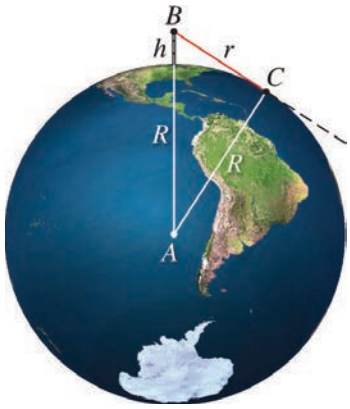

FIGURE 1.10 Distance from the top of the Willis Tower (B) to the horizon (C).

It seems obvious from this sketch that the farthest point (point C) that one can see from the top of the Willis Tower (point B) is where the line of sight just touches the surface of the Earth tangentially. Any point on Earth's surface farther away from the Willis Tower is hidden from view (below the dashed line segment). The viewing range is then given by the distance r between that surface point C and the observation deck (point B) on top of the tower, at height h. Included in the sketch is also a line from the center of Earth (point A) to the foot of the Willis Tower. It has length R, which is the

radius of Earth. Another line of the same length, R, is drawn to the point where the line of sight touches the Earth's surface tangentially.

RESEARCH

As you can see from the sketch, a line drawn from the center of the Earth to the point where the line of sight touches the surface (A to C) will form a right angle with that line of sight (B to C); that is, the three points A, B, and C form the corners of a right triangle. This is the key insight, which enables us to use trigonometry and the Pythagorean Theorem to attack the solution of this problem. Examining the sketch in Figure 1.10, we find

$$r^2 + R^2 = (R + h)^2 \, .$$

SIMPLIFY

Remember, we want to find the distance to the horizon, for which we used the symbol r in the previous equation. Isolating that variable on one side of our equation gives

$$r^2 = (R + h)^2 - R^2.$$

Now we can simplify the square and obtain

$$r^2 = R^2 + 2hR + h^2 - R^2 = 2hR + h^2.$$

Finally, we take the square root and obtain our final algebraic answer:

$$r \ = \sqrt{2hR + h^2} \, .$$

CALCULATE

Now we are ready to insert numbers. The accepted value for the radius of Earth is $R = 6.37 \cdot 10^6 \text{ m},$ and $h = 413 \text{ m} = 4.13 \cdot 10^2 \text{ m}$ was given in the problem. This leads to

$$r = \sqrt{2\left(4.13 \cdot 10^2 \text{ m}\right)\left(6.37 \cdot 10^6 \text{ m}\right) + \left(4.13 \cdot 10^2 \text{ m}\right)^2} = 7.25382 \cdot 10^4 \text{ m}.$$

ROUND

The Earth's radius was given to three-digit precision, as was the elevation of the eye level of the observer. So we round to three digits and give our final result as

$$r = 7.25 \cdot 10^4 \text{ m} = 72.5 \text{ km}.$$

DOUBLE-CHECK

Always check the units first. Since the problem asked "how far," the answer needs to be a distance, which has the dimension of length and thus the base unit meter. Our answer passes this first check. What about the magnitude of our answer? Since the Willis Tower is almost 0.5 kilometer high, we expect the viewing range to be at least several

kilometers; so a multikilometer range for the answer seems reasonable. Lake Michigan is slightly more than 80 km wide, if you look toward the east from Chicago. Our answer then implies that you cannot see the Michigan shore of Lake Michigan if you stand on top of the Willis Tower. Experience shows that this is correct, which gives us additional confidence in our answer.

Concept Check 1.4

Two sailors are at the tops of their ships' masts in the open ocean. The mast of ship A is twice as high as that of ship B. How much farther can sailor A see than sailor B?

a) no farther

b) a little more than 40% farther

c) twice as far

d) almost three times as far

e) four times as far

Problem-Solving Guidelines: Limits

In Solved Problem 1.2, we found a handy formula, $r = \sqrt{2hR + h^2}$ for how far one can see on the surface of Earth from an elevation h, where R is the radius of Earth. There is another test that we can perform to check the validity of this formula. We did not include it in the Double-Check step, because it deserves separate consideration. This general problem-solving technique is examining the limits of an equation.

What does "examining the limits" mean? In terms of Solved Problem 1.2, it means that instead of just inserting the given number for h into our formula and computing the solution, we can also step back and think about what should happen to the distance r one can see if h becomes very large or very small. Obviously, the smallest that h can become is zero. In this case, r will also approach zero. This is expected, of course; if your eye level is at ground level, you cannot see very far. On the other hand, we can ponder what happens if h becomes large compared to the radius of Earth (see Figure 1.11). (Yes, it is impossible to build a tower that tall but h could also stand for the altitude of a satellite above ground.) In that case, we expect that the viewing range will eventually simply be the height h. Our formula also bears out this expectation, because as h becomes large compared to R, the first term in the square root can be neglected, and we find $\lim_{h\to\infty} \sqrt{2hR + h^2} = h$.

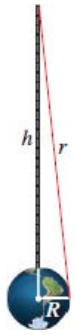

FIGURE 1.11 Viewing range in the limit of very large h.

What we have illustrated by this example is a general guideline: If you derive a formula, you can check its validity by substituting extreme values of the variables in the formula and checking if these limits agree with common sense. Often the formula simplifies drastically at a limit. If your formula has a limiting behavior that is correct, it does not necessarily mean that the formula itself is correct, but it gives you additional confidence in its validity.

Problem-Solving Guidelines: Ratios

Another very common class of physics problems asks what happens to a quantity that depends on a certain parameter if that parameter changes by a given factor. These problems provide excellent insight into physical concepts and take almost no time to do. This is true, in general, *if* two conditions are met: First, you have to know what formula to use; and second, you have to know how to solve this general class of problems. But that is a big *if*. Studying will equip your memory with the correct formulas, but you need to acquire the skill of solving problems of this general type.

Here is the trick: Write down the formula that connects the dependent quantity to the parameter that changes. Write it twice, once with the dependent quantity and the parameters indexed (or labeled) with 1 and once with them indexed with 2. Then form ratios of the indexed quantities by dividing the right-hand sides and the left-hand sides of the two equations. Next, insert the factor of change for the parameter (expressed as a ratio) and do the calculation to find the factor of change for the dependent quantity (also expressed as a ratio).

Here is an example that demonstrates this method.

EXAMPLE 1.3 Change in Volume

PROBLEM

If the radius of a cylinder increases by a factor of 2.73, by what factor does the volume change? Assume that the height of the cylinder stays the same.

SOLUTION

The formula that connects the volume of a cylinder, V, and its radius, r, is

$$V = \pi r^2 h.$$

The way the problem is phrased, V is the dependent quantity and r is the parameter it depends on. The height of the cylinder, h, also appears in the equation but remains constant, according to the problem statement.

Following the general problem-solving guideline, we write the equation twice, once with 1 as indexes and once with 2:

$$V_1 = \pi r_1^2 h$$
$$V_2 = \pi r_2^2 h.$$

Now we divide the second equation by the first, obtaining

$$\frac{V_2}{V_1} = \frac{\pi r_2^2 h}{\pi r_1^2 h} = \left(\frac{r_2}{r_1}\right)^2.$$

As you can see, h did not receive an index because it stayed constant in this problem; it canceled out in the division.

The problem states that the change in radius is given by:

$$r_2 = 2.73 r_1.$$

We substitute for r_2 in our ratio:

$$\frac{V_2}{V_1} = \left(\frac{r_2}{r_1}\right)^2 = \left(\frac{2.73 r_1}{r_1}\right)^2 = 2.73^2 = 7.4529,$$

or

$$V_2 = 7.45 V_1,$$

where we have rounded the solution to the three significant digits that the quantity given in the problem had. Thus, the answer is that the volume of the cylinder increases by a factor of 7.45 when you increase its radius by a factor of 2.73.

Problem-Solving Guidelines: Estimation

Sometimes you don't need to solve a physics problem exactly. When an estimate is all that is asked for, knowing the order of magnitude of some quantity is enough. For example, an answer of $1.24 \cdot 10^{20}$ km is for most purposes not much different from $1 \cdot 10^{20}$ km. In such cases, you can round off all the numbers in a problem to the nearest power of 10 and carry out the necessary arithmetic. For example, the calculation in Solved Problem 1.1 reduces to

$$\frac{(20.8\,\text{cm})^2 \cdot (12.2\,\text{cm})}{4\pi} \approx \frac{\left(2.10^1\,\text{cm}\right)^2 \cdot (10\,\text{cm})}{10} = \frac{4.10^3\,\text{cm}^3}{10} = 400\,\text{cm}^3,$$

which is pretty close to our answer of $420.\ \text{cm}^3$. Even an answer of $100\,\text{cm}^3$ (rounding 20.8 cm to 10 cm) has the correct order of magnitude for the volume. Notice that you can often round the number π to 3 or round π^2 to 10. With practice, you can find more tricks of approximation like these that can make estimations simpler and faster.

The technique of gaining useful results through careful estimation was made famous by the 20th-century physicist Enrico Fermi (1901–1954), who estimated the energy released by the Trinity nuclear explosion on July 16, 1945, near Socorro, New Mexico, by observing how far a piece of paper was blown by the wind from the blast. There is a class of estimation problems called *Fermi problems* that can yield interesting results when reasonable assumptions are made about quantities that are not known exactly.

Estimates are useful to gain insight into a problem before turning to more complicated methods of calculating a precise answer. For example, one could estimate how many tacos people eat and how many taco stands there are in town before investing in a complete business plan to construct a taco stand. In order to practice estimation skills, let's estimate the amount of carbon dioxide that is added to Earth's atmosphere annually by humans breathing.

EXAMPLE 1.4 Greenhouse Gas Production

PROBLEM

The concentration of greenhouse gases, including carbon dioxide (CO_2), in the Earth's atmosphere is increasing. Estimate how much CO_2 is added to the atmosphere each year by humans breathing.

SOLUTION

Since we are asked to estimate, we have to come up with the order of magnitude of the amount. The precise number does not matter so much. Let's start with the amount of CO_2 in one breath, estimate how many breaths each of us takes per year, and then multiply by the number of humans on the planet.

When we breathe, we take in air that is a mixture of 21% oxygen and 78% nitrogen (plus traces of other gases). We exhale air that has approximately 16% oxygen and 5% CO_2. Even though our lung capacity is approximately 3 to 5 L, we only use about 10% of that capacity in normal breathing. So, let's say that one breath of air is approximately 0.4 L. Then, 5% of 0.4 L is $2 \cdot 10^{-2}$ L. You may remember from high school science that 22.4 L of gas comprise 1 mole, and that 1 mole of CO_2 has a mass of $2 \cdot 16\ \text{g} + 12\ \text{g} = 44\ \text{g}$. This means that in one breath we produce

$$m_1 = \frac{\left(2 \cdot 10^{-2}\ \text{L}\right)(44\ \text{g})}{22.4\ \text{L}} \approx 4 \cdot 10^{-2}\ \text{g}$$

of CO_2.

We take a breath of air about once every 4 seconds. (You can use a stopwatch to convince yourself that this is true, or you can count the number of breaths you take in a minute.) This means that we breathe about 1000 times per hour, and since a year has about 10,000 hours, we take $N = 10^7$ breaths per year.

Now, we can put all this together and get our estimate. Humanity (~7 billion, or $7 \cdot 10^9$, humans) produces about

$$M = Nm_1N_{\text{humans}} = 10^7\left(4 \cdot 10^{-2}\ \text{g}\right)\left(7 \cdot 10^9\right) = 3 \cdot 10^{15}\ \text{g} = 3 \cdot 10^{12}\ \text{kg}$$

of CO_2.

In other words, our estimate indicates that humans add approximately 3 billion metric tons of CO_2 to Earth's atmosphere each year just by breathing. Remember, this is just an estimate; we cannot be sure of the mantissa, but we can be reasonably confident of the exponent. Our answer certainly is billions of tons, but we cannot be sure if it is 1 or 3 billion.

For comparison, measurements indicate that the amount of CO_2 in the atmosphere increases by approximately 20 billion metric tons per year. This amount is clearly much higher than our estimate, but is mainly due to burning of fossil fuels (more on this topic in Chapter 18).

Concept Check 1.5

Estimate the number of gallons of gasoline consumed each day in the United States by commuters driving to work.

a) 10,000 gallons

b) 100,000 gallons

c) 1,000,000 gallons

d) 10,000,000 gallons

e) 100,000,000 gallons

1.6 Vectors

Vectors are mathematical descriptions of quantities that have both magnitude and direction. The magnitude of a vector is a nonnegative number, often combined with a physical unit. Many vector quantities are important in physics and, indeed, in all of science. Therefore, before we start this study of physics, you need to be familiar with vectors and some basic vector operations.

Vectors have a starting point and an ending point. For example, consider a flight from Seattle to New York. To represent the change of the plane's position, we can draw an arrow from the plane's departure point to its destination (Figure 1.12). (Real flight paths are not exactly straight lines due to the fact that the Earth is a sphere and due to airspace restrictions and air traffic regulations, but a straight line is a reasonable approximation for our purpose.) This arrow represents a *displacement vector,* which always goes from somewhere to somewhere else. Any vector quantity has a magnitude and a direction. If the vector represents a physical quantity, such as displacement, it will also have a physical unit. A quantity that can be represented without giving a direction is called a **scalar**. A scalar quantity has just a magnitude and possibly a physical unit. Examples of scalar quantities are time and temperature.

FIGURE 1.12 Flight path from Seattle to New York as an example of a vector.

This book denotes a vector quantity by a letter with a small horizontal arrow pointing to the right above it. For example, in the drawing of the trip from Seattle to New York (Figure 1.12), the displacement vector has the symbol $\vec{C}$. In the rest of this section, you will learn how to work with vectors: how to add and subtract them and how to multiply them. In order to perform these operations, it is very useful to introduce a coordinate system in which to represent vectors.

Cartesian Coordinate System

A **Cartesian coordinate system** is defined as a set of two or more axes with angles of 90° between each pair. These axes are said to be orthogonal to each other. In a two-dimensional space, the coordinate axes are typically labeled x and y. We can then uniquely specify any point P in the two-dimensional space by giving its coordinates P_x and P_y along the two coordinate axes, as shown in Figure 1.13. We will use the notation (P_x, P_y) to specify a point in terms of its coordinates. In Figure 1.13, for example, the point P has the position (3.3,3.8), because its x-coordinate has a value of 3.3 and its y-coordinate has a value of 3.8. Note that each coordinate is a number and can have a positive or negative value or be zero.

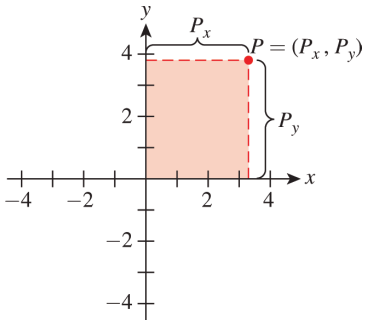

FIGURE 1.13
Representation of a point P in two-dimensional space in terms of its Cartesian coordinates.

We can also define a one-dimensional coordinate system, for which any point is located on a single straight line, conventionally called the x-axis. Any point in this one-dimensional space is then uniquely defined by specifying one number, the value of the x-coordinate, which again can be negative, zero, or positive (Figure 1.14). The point P in Figure 1.14 has the x-coordinate $P_x = -2.5$.

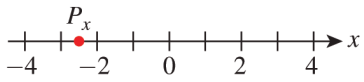

FIGURE 1.14
Representation of a point P in a one-dimensional Cartesian coordinate system.

Clearly, one- and two-dimensional coordinate systems are easy to draw, because the surface of paper has two dimensions. In a three-dimensional coordinate system, the third coordinate axis is perpendicular to the other two; thus, to be represented accurately, it would have to stick straight out of the plane of the page. In order to draw a three-dimensional coordinate system, we have to rely on conventions that make use of the techniques for perspective drawings. We represent the third axis by a line that is at a 45° angle with the other two (Figure 1.15).

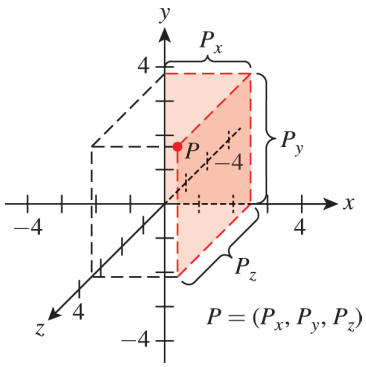

FIGURE 1.15
Representation of a point *P* in a three-dimensional space in terms of its Cartesian coordinates.

In a three-dimensional space, we have to specify three numbers to uniquely determine the coordinates of a point. We use the notation $P = (P_x, P_y, P_z)$ to accomplish this. It is possible to construct Cartesian coordinate systems with more than three orthogonal axes, although they are almost impossible to visualize. Modern string theories (described in Chapter 39), for example, are usually constructed in 10-dimensional spaces. However, for the purposes of this book and for almost all of physics, three dimensions are sufficient. As a matter of fact, for most applications, the essential mathematical and physical understanding can be obtained from two-dimensional representations.

Cartesian Representation of Vectors

The example of the flight from Seattle to New York established that vectors are characterized by two points: start and finish, represented by the tail and head of an arrow, respectively. Using the Cartesian representation of points, we can define the Cartesian representation of a displacement vector as the difference in the coordinates of the end point and the starting point. Since the difference between the two points for a vector is all that matters, we can shift the vector around in space as much as we like. As long as we do not change the length or direction of the arrow, the vector remains mathematically the same. Consider the two vectors in Figure 1.16.

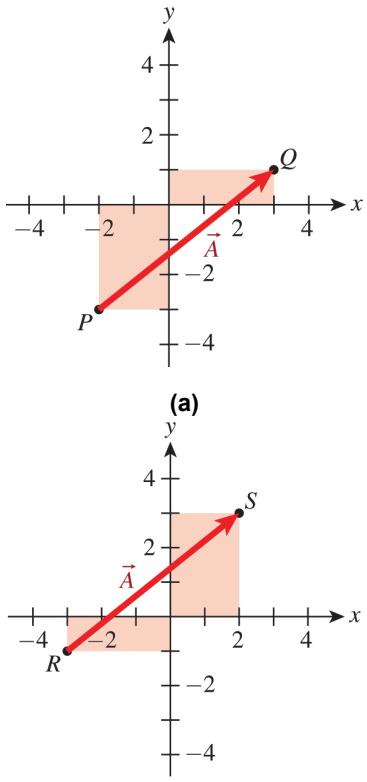

FIGURE 1.16 Cartesian representations of a vector $\vec{A}$. (a) Displacement vector from *P* to *Q;* (b) displacement vector from *R* to *S.*

Figure 1.16a shows the displacement vector $\vec{A}$ that points from point $P = (-2, -3)$ to point $Q = (3, 1)$. With the notation just introduced, the **components** of $\vec{A}$ are the coordinates of point Q minus those of point P, $\vec{A} = (3 - (-2), 1 - (-3)) = (5, 4)$. Figure 1.16b shows another vector from point $R = (-3, -1)$ to point $S = (2, 3)$. The difference between these coordinates is $(2 - (-3), 3 - (-1)) = (5, 4)$, which is the same as the vector $\vec{A}$ pointing from *P* to *Q*.

For simplicity, we can shift the beginning of a vector to the origin of the coordinate system, and the components of the vector will be the same as the coordinates of its end point (Figure 1.17). As a result, we see that we can represent a vector in Cartesian coordinates as

$$\vec{A} = (A_x, A_y) \text{ in two-dimensional space} \tag{1.7}$$

$$\vec{A} = (A_x, A_y, A_z) \text{ in three-dimensional space} \tag{1.8}$$

where A_x, A_y, and A_z are numbers. Note that the notation for a point in Cartesian coordinates is similar to the notation for a vector in Cartesian coordinates. Whether the notation specifies a point or a vector will be clear from the context of the reference.

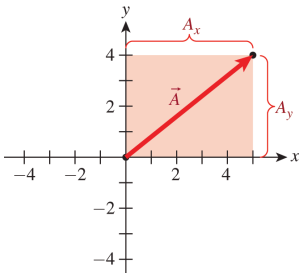

FIGURE 1.17 Cartesian components of vector $\vec{A}$ in two dimensions.

Graphical Vector Addition and Subtraction

Suppose that the direct flight from Seattle to New York shown in Figure 1.12 was not available, and you had to make a connection through Dallas (Figure 1.18). Then the displacement vector $\vec{C}$ for the flight from Seattle to New York is the sum of a displacement vector $\vec{A}$ from Seattle to Dallas and a displacement vector $\vec{B}$ from Dallas to New York:

$$\vec{C} = \vec{A} + \vec{B}. \tag{1.9}$$

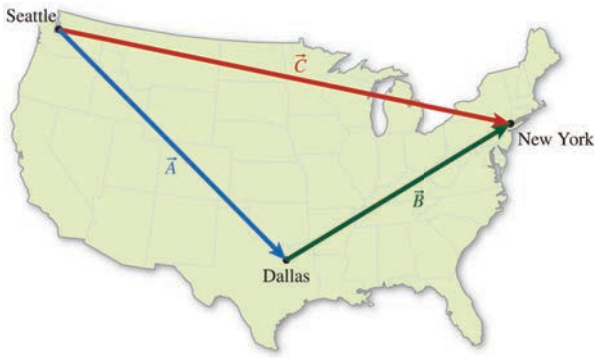

FIGURE 1.18 Direct flight versus one-stop flight as an example of vector addition.

This example shows the general procedure for vector addition in a graphical way: Move the tail of vector $\vec{B}$ to the head of vector $\vec{A}$; then the vector from the tail of vector $\vec{A}$ to the head of vector $\vec{B}$ is the sum vector, or **resultant,** of the two.

If you add two real numbers, the order does not matter: 3+5 = 5+3. This property is called the *commutative property of addition*. Vector addition is also commutative:

$$\vec{A} + \vec{B} = \vec{B} + \vec{A}. \tag{1.10}$$

Figure 1.19 demonstrates this commutative property of vector addition graphically. It shows the same vectors as in Figure 1.18, but also shows the beginning of vector $\vec{A}$ moved to the tip of vector $\vec{B}$ (dashed arrows)—note that the resultant vector is the same as before.

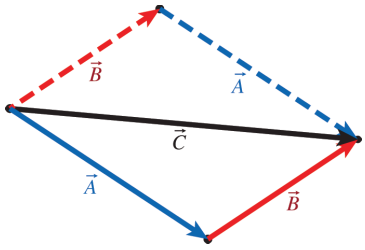

FIGURE 1.19 Commutative property of vector addition.

Next, the inverse (or reverse or negative) vector, $-\vec{C}$, of the vector $\vec{C}$ is a vector with the same length as $\vec{C}$ but pointing in the opposite direction (Figure 1.20). For the vector representing the flight from Seattle to New York, for example, the inverse vector is the return trip. Clearly, if you add $\vec{C}$ and its inverse vector, $-\vec{C}$, you end up at the point you started from. Thus, we find

$$\vec{C} + \left(-\vec{C}\right) = \vec{C} - \vec{C} = (0, 0, 0), \tag{1.11}$$

and the magnitude is zero, $\left|\vec{C} - \vec{C}\right| = 0$. This seemingly simple identity shows that we can treat vector subtraction as vector addition, by simply adding the inverse vector. For example, the vector $\vec{B}$ in Figure 1.19 can be obtained as $\vec{B} = \vec{C} - \vec{A}$. Therefore, vector addition and subtraction follow exactly the same rules as the addition and subtraction of real numbers.

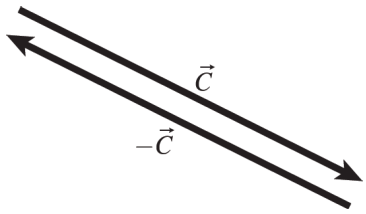

FIGURE 1.20 Inverse vector $-\vec{C}$ of a vector $\vec{C}$.

Vector Addition Using Components

Graphical vector addition illustrates the concepts very well, but for practical purposes the component method of vector addition is much more useful. (This is because calculators are easier to use and much more precise than rulers and graph paper.) Let's consider the component method for addition of three-dimensional vectors. The equations for two-dimensional vectors are special cases that arise by neglecting the z-components. Similarly, the one-dimensional equation can be obtained by neglecting all y- and z-components.

If you add two three-dimensional vectors, $\vec{A} = (A_x, A_y, A_z)$ and $\vec{B} = (B_x, B_y, B_z)$ the resulting vector is

$$\vec{C} = \vec{A} + \vec{B} = (A_x, A_y, A_z) + (B_x, B_y, B_z) = (A_x + B_x, A_y + B_y, A_z + B_z). \quad \textbf{(1.12)}$$

In other words, the components of the sum vector are the sums of the components of the individual vectors:

$$\begin{aligned} C_x &= A_x + B_x \\ C_y &= A_y + B_y \\ C_z &= A_z + B_z. \end{aligned} \quad \textbf{(1.13)}$$

The relationship between graphical and component methods is illustrated in Figure 1.21. Figure 1.21a shows two vectors $\vec{A} = (4, 2)$ and $\vec{B} = (3, 4)$ in two-dimensional space, and Figure 1.21b displays their sum vector $\vec{C}$ = (4+3,2+4) = (7,6). Figure 1.21b clearly shows that $C_x = A_x + B_x$, because the whole is equal to the sum of its parts.

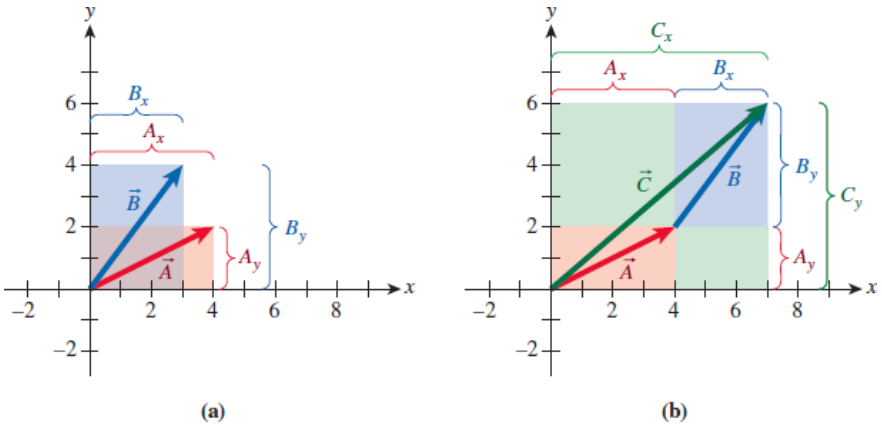

FIGURE 1.21 Vector addition by components. (a) Components of vectors $\vec{A}$ and $\vec{B}$; (b) the components of the resultant vector are the sums of the components of the individual vectors.

In the same way, we can take the difference $\vec{D} = \vec{A} - \vec{B}$, and the Cartesian components of the difference vector are given by

$$\begin{aligned} D_x &= A_x - B_x \\ D_y &= A_y - B_y \\ D_z &= A_z - B_z. \end{aligned} \tag{1.14}$$

Multiplication of a Vector with a Scalar

What is $\vec{A} + \vec{A} + \vec{A}$? If your answer to this question is $3\vec{A}$, you already understand multiplying a vector with a scalar. The vector that results from multiplying the vector $\vec{A}$ with the scalar 3 is a vector that points in the same direction as the original vector $\vec{A}$ but is 3 times as long.

Multiplication of a vector with an arbitrary positive scalar—that is, a positive number—results in another vector that points in the same direction but has a magnitude that is the product of the magnitude of the original vector and the value of the scalar. Multiplication of a vector by a negative scalar results in a vector pointing in the opposite direction to the original with a magnitude that is the product of the magnitude of the original vector and the magnitude of the scalar.

Again, the component notation is useful. For the multiplication of a vector $\vec{A}$ with a scalar *s,* we obtain:

$$\vec{E} = s\vec{A} = s(A_x, A_y, A_z) = (sA_x, sA_y, sA_z). \tag{1.15}$$

In other words, each component of the vector $\vec{A}$ is multiplied by the scalar in order to arrive at the components of the product vector:

$$\begin{aligned} E_x &= sA_x \\ E_y &= sA_y \\ E_z &= sA_z. \end{aligned} \tag{1.16}$$

Unit Vectors

There is a set of special vectors that make much of the math associated with vectors easier. Called **unit vectors,** they are vectors of magnitude 1 directed along the main coordinate axes of the coordinate system. In two dimensions, these vectors point in the positive x-direction and the positive y-direction. In three dimensions, a third unit vector points in the positive z-direction. In order to distinguish these as unit vectors, we give them the symbols $\hat{x}$, $\hat{y}$, and $\hat{z}$. Their component representation is

$$\begin{aligned} \hat{x} &= (1, 0, 0) \\ \hat{y} &= (0, 1, 0) \\ \hat{z} &= (0, 0, 1). \end{aligned} \tag{1.17}$$

Figure 1.22a shows the unit vectors in two dimensions, and Figure 1.22b shows the unit vectors in three dimensions.

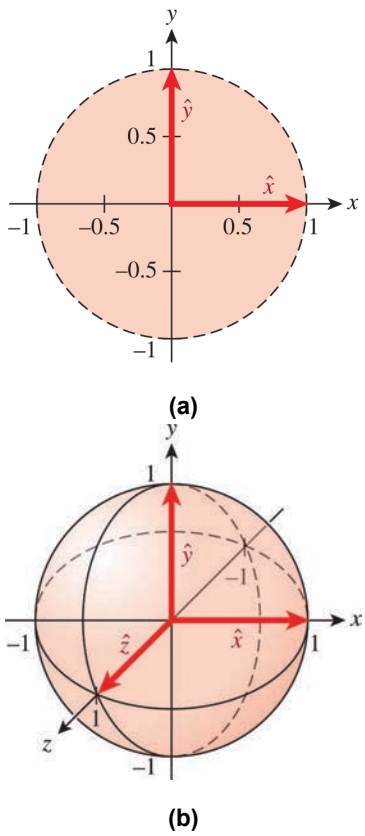

FIGURE 1.22 Cartesian unit vectors in (a) two and (b) three dimensions.

What is the advantage of unit vectors? We can write any vector as a sum of these unit vectors instead of using the component notation; each unit vector is multiplied by the corresponding Cartesian component of the vector:

$$\begin{aligned}\overrightarrow{A} &= (A_x, A_y, A_Z) \\ &= (A_x, 0, 0) + (0, A_y, 0) + (0, 0, A_z) \\ &= A_x(1, 0, 0) + A_y(0, 1, 0) + A_z(0, 0, 1) \\ &= A_x\widehat{x} + A_y\hat{y} + A_z\hat{z}.\end{aligned} \tag{1.18}$$

In two dimensions, we have

$$\overrightarrow{A} = A_x\widehat{x} + A_y\hat{y}. \tag{1.19}$$

This unit vector representation of a general vector will be particularly useful for multiplying two vectors.

Vector Length and Direction

If we know the component representation of a vector, how can we find its length (magnitude) and the direction it is pointing in? Let's look at the most important case: a vector in two dimensions. In two dimensions, a vector $\vec{A}$ can be specified uniquely by giving the two Cartesian components, A_x and A_y. We can also specify the same vector by giving two other numbers: its length A and its angle θ with respect to the positive x-axis.

Let's take a look at Figure 1.23 to see how we can determine A and θ from A_x and A_y. Figure 1.23a shows the graphical representation of equation 1.19. The vector $\vec{A}$ is the sum of the vectors $A_x\hat{x}$ and $A_y\hat{y}$. Since the unit vectors $\hat{x}$ and $\hat{y}$ are by definition orthogonal to each other, these vectors form a 90° angle. Thus, the three vectors $\vec{A}$, $A_x\hat{x}$, and $A_y\hat{y}$ form a right triangle with side lengths A, A_x, and A_y, as shown in Figure 1.23b.

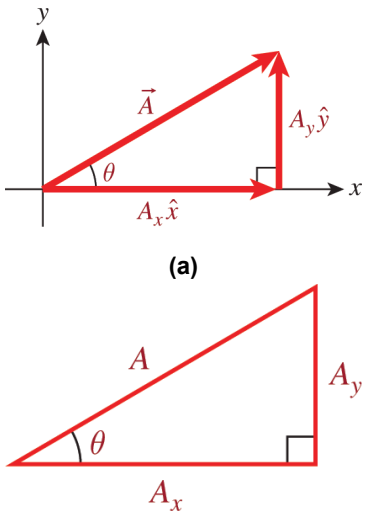

FIGURE 1.23 Length and direction of a vector. (a) Cartesian components A_x and A_y; (b) length A and angle θ.

Now we can employ basic trigonometry to find θ and A. Using the Pythagorean Theorem results in

$$A = \sqrt{A_x^2 + A_y^2}. \tag{1.20}$$

We can find the angle θ from the definition of the tangent function

$$\theta = \tan^{-1}\frac{A_y}{A_x}. \tag{1.21}$$

In using equation 1.21, you must be careful that θ is in the correct quadrant. We can also invert equations 1.20 and 1.21 to obtain the Cartesian components of a vector of given length

and direction:

$$A_x = A\cos\theta \tag{1.22}$$

$$A_y = A\sin\theta. \tag{1.23}$$

You will encounter these trigonometric relations again and again throughout introductory physics. If you need to refamiliarize yourself with trigonometry, consult the mathematics primer provided in Appendix A.

Scalar Product of Vectors

Above we saw how to multiply a vector with a scalar. Now we will define one way of multiplying a vector with a vector and obtain the **scalar product**. The scalar product of two vectors $\vec{A}$ and $\vec{B}$ is defined as

$$\vec{A} \bullet \vec{B} = \left|\vec{A}\right| \left|\vec{B}\right| \cos\alpha, \qquad \textbf{(1.24)}$$

where α is the angle between the vectors $\vec{A}$ and $\vec{B}$, as shown in Figure 1.24. Note the use of the larger dot ($\cdot$) as the multiplication sign for the scalar product between vectors, in contrast to the smaller dot ($\cdot$) that is used for the multiplication of scalars. Because of the dot, the scalar product is often referred to as the *dot product*.

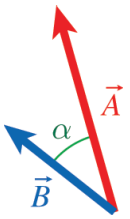

FIGURE 1.24 Two vectors $\vec{A}$ and $\vec{B}$ and the angle α between them.

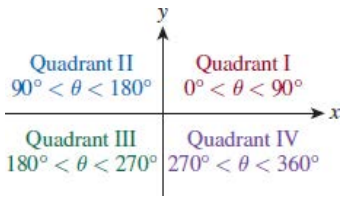
Concept Check 1.6

Into which quadrant do each of the following vectors point?



a) $A = (A_x, A_y)$ with A_x = 1.5 cm, A_y = -1.0 cm

b) a vector with length 2.3 cm and direction angle 131°

c) the inverse vector of B = (0.5 cm, 1.0 cm)

d) the sum of the unit vectors in the x- and y-directions

If two vectors form a 90° angle, then the scalar product has the value zero. In this case, the two vectors are orthogonal to each other. The scalar product of a pair of orthogonal vectors is zero.

If $\overrightarrow{A}$ and $\overrightarrow{B}$ are given in Cartesian coordinates as $\overrightarrow{A} = (A_x, A_y, A_z)$ and $\overrightarrow{B} = (B_x, B_y, B_z)$, then their scalar product can be shown to be equal to:

$$\overrightarrow{A} \bullet \overrightarrow{B} = (A_x, A_y, A_z) \bullet (B_x, B_y, B_z) = A_x B_x + A_y B_y + A_z B_z. \qquad \textbf{(1.25)}$$

From equation 1.25, we can see that the scalar product has the commutative property:

$$\overrightarrow{A} \bullet \overrightarrow{B} = \overrightarrow{B} \bullet \overrightarrow{A}. \qquad \textbf{(1.26)}$$

This result is not surprising, since the commutative property also holds for the multiplication of two scalars.

For the scalar product of any vector with itself, we have, in component notation, $\overrightarrow{A} \bullet \overrightarrow{A} = A_x^2 + A_y^2 + A_z^2$. Then, from equation 1.24, we find $\overrightarrow{A} \bullet \overrightarrow{A} = \left|\overrightarrow{A}\right|\left|\overrightarrow{A}\right| \cos\alpha = \left|\overrightarrow{A}\right|\left|\overrightarrow{A}\right| = \left|\overrightarrow{A}\right|^2$ (because the angle between the vector $\overrightarrow{A}$ and itself is zero, and the cosine of that angle has the value 1). Combining these two equations, we obtain the expression for the length of a vector that was introduced in the previous subsection:

$$\left|\overrightarrow{A}\right| = \sqrt{A_x^2 + A_y^2 + A_z^2}. \qquad \textbf{(1.27)}$$

We can also use the definition of the scalar product to compute the angle between two arbitrary vectors in three-dimensional space:

$$\overrightarrow{A} \bullet \overrightarrow{B} = \left|\overrightarrow{A}\right|\left|\overrightarrow{B}\right| \cos\alpha \Rightarrow \cos\alpha \frac{\overrightarrow{A} \bullet \overrightarrow{B}}{\left|\overrightarrow{A}\right|\left|\overrightarrow{B}\right|} \Rightarrow \alpha = \cos^{-1}\left(\frac{\overrightarrow{A} \bullet \overrightarrow{B}}{\left|\overrightarrow{A}\right|\left|\overrightarrow{B}\right|}\right). \qquad \textbf{(1.28)}$$

For the scalar product, the same distributive property that is valid for the conventional multiplication of numbers holds:

$$\overrightarrow{A} \bullet \left(\overrightarrow{B} + \overrightarrow{C}\right) = \overrightarrow{A} \bullet \overrightarrow{B} + \overrightarrow{A} \bullet \overrightarrow{C}. \qquad \textbf{(1.29)}$$

The following example puts the scalar product to use.

EXAMPLE 1.5 Angle Between Two Position Vectors

PROBLEM

What is the angle α between the two position vectors shown in Figure 1.25, $\overrightarrow{A} = (4.00, 2.00, 5.00)$ cm and $\overrightarrow{B} = (4.50, 4.00, 3.00)$ cm?

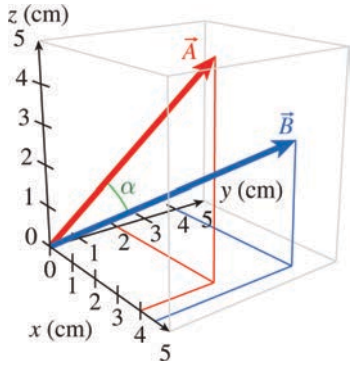


FIGURE 1.25 Calculating the angle between two position vectors.

SOLUTION

To solve this problem, we have to put the numbers for the components of each of the two vectors into equation 1.27 and equation 1.25, and then use equation 1.28:

$$\left|\overrightarrow{A}\right| = \sqrt{4.00^2 + 2.00^2 + 5.00^2}\,\text{cm} = 6.71\,\text{cm}$$

$$\left|\overrightarrow{B}\right| = \sqrt{4.50^2 + 4.00^2 + 3.00^2}\,\text{cm} = 6.73\,\text{cm}$$

$$\overrightarrow{A} \bullet \overrightarrow{B} = A_x B_x + A_y B_y + A_z B_z = (4.00 \cdot 4.50 + 2.00 \cdot 4.00 + 5.00 \cdot 3.00)\,\text{cm}^2 =$$

$$\Rightarrow \alpha = \cos^{-1}\left(\frac{41.0\,\text{cm}^2}{6.71\ \text{cm} \cdot 6.73\ \text{cm}}\right) = 24.7^\circ.$$

Scalar Product for Unit Vectors

Previously we introduced unit vectors in the three-dimensional Cartesian coordinate system: $\widehat{x} = (1, 0, 0), \hat{y} = (0, 1, 0)$, and $\hat{z} = (0, 0, 1)$. With our definition (1.25) of the scalar product, we find

$$\widehat{x} \bullet \widehat{x} = \hat{y} \bullet \hat{y} = \hat{z} \bullet \hat{z} = 1 \qquad \textbf{(1.30)}$$

and

$$\begin{aligned} \widehat{x} \bullet \hat{y} = \widehat{x} \bullet \hat{z} = \hat{y} \bullet \hat{z} = 0 \\ \hat{y} \bullet \widehat{x} = \hat{z} \bullet \widehat{x} = \hat{z} \bullet \hat{y} = 0 \end{aligned} \qquad \textbf{(1.31)}$$

Self-Test Opportunity 1.1

Show that equations 1.30 and 1.31 are correct by using equation 1.25 and the definitions of the unit vectors.

Now we see why the unit vectors are called that: Their scalar products with themselves have the value 1. Thus, the unit vectors have length 1, or unit length, according to equation 1.27. In addition, any pair of different unit vectors has a scalar product that is zero, meaning that these vectors are orthogonal to each other. Equations 1.30 and 1.31 thus state that the unit vectors 1.31, and thus state that the unit vectors form an orthonormal set of vectors, which makes them extremely useful for the description of physical systems. $\widehat{x}$, $\hat{y}$, and $\hat{z}$ form an orthonormal set of vectors, which makes them extremely useful for the description of physical systems.

Geometrical Interpretation of the Scalar Product

In the definition of the scalar product $\vec{A} \bullet \vec{B} = \left|\vec{A}\right|\left|\vec{B}\right| \cos\alpha$ (equation 1.24), we can interpret $\left|\vec{A}\right| \cos\alpha$ as the projection of the vector $\vec{A}$ onto the vector $\vec{B}$ (Figure 1.26a). In this drawing, the line $\left|\vec{A}\right| \cos\alpha$ is rotated by 90° to show the geometrical interpretation of the scalar product as the area of a rectangle with sides $\left|\vec{A}\right| \cos\alpha$ and $\left|\vec{B}\right|$ In the same way, we can interpret $\left|\vec{B}\right| \cos\alpha$ as the projection of the vector $\vec{B}$ onto the vector $\vec{A}$ and construct a rectangle with side lengths $\left|\vec{B}\right| \cos\alpha$ and $\left|\vec{A}\right|$ (Figure 1.26b). The areas of the two yellow rectangles in Figure 1.26 are identical and are equal to the scalar product of the two vectors $\vec{A}$ and $\vec{B}$.

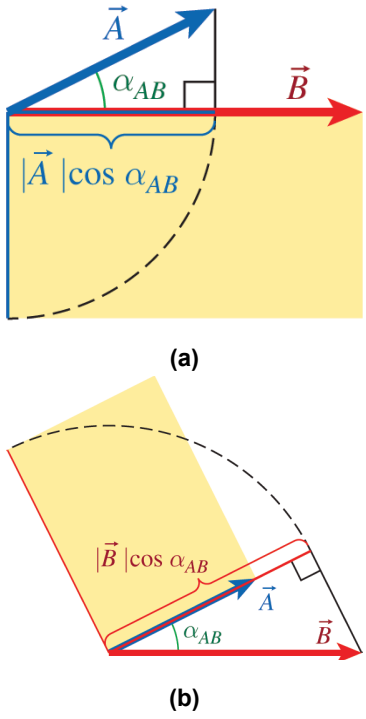

FIGURE 1.26 Geometrical interpretation of the scalar product as an area. (a) The projection of $\vec{A}$ onto $\vec{B}$. (b) The projection of $\vec{B}$ onto $\vec{A}$.

Finally, if we substitute from equation 1.28 for the cosine of the angle between the two vectors, the projection $\left|\vec{A}\right| \cos\alpha$ of the vector $\vec{A}$ onto the vector $\vec{B}$ can be written as

$$\left|\vec{A}\right| \cos\alpha = \left|\vec{A}\right| \frac{\vec{A} \bullet \vec{B}}{\left|\vec{A}\right|\left|\vec{B}\right|} = \frac{\vec{A} \bullet \vec{B}}{\left|\vec{B}\right|},$$

and the projection $\left|\overrightarrow{B}\right| \cos\ \alpha\ $ of the vector $\overrightarrow{B}$ onto the vector $\overrightarrow{A}$ can be expressed as

$$\left|\overrightarrow{B}\right| \cos\alpha = \frac{\overrightarrow{A} \bullet \overrightarrow{B}}{\left|\overrightarrow{A}\right|}.$$

Vector Product

The vector product (or cross product) between two vectors $\vec{A} = (A_x, A_y, A_z)$ and $\vec{B} = (B_x, B_y, B_z)$ is defined as

$$\begin{aligned} \vec{C} &= \vec{A} \times \vec{B} \\ C_x &= A_y B_z - A_z B_y \\ C_y &= A_z B_x - A_x B_z \\ C_z &= A_x B_y - A_y B_x. \end{aligned} \tag{1.32}$$

In particular, for the vector products of the Cartesian unit vectors, this definition implies

$$\begin{aligned} \hat{x} \times \hat{y} &= \hat{z} \\ \hat{y} \times \hat{z} &= \hat{x} \\ \hat{z} \times \hat{x} &= \hat{y} \end{aligned} \tag{1.33}$$

The absolute magnitude of the vector $\vec{C}$ is given by

$$\left|\vec{C}\right| = \left|\vec{A}\right|\left|\vec{B}\right| \sin\theta. \tag{1.34}$$

Here θ is the angle between $\vec{A}$ and $\vec{B}$ as shown in Figure 1.27. This result implies that the magnitude of the vector product of two vectors is at its maximum when $\vec{A} \perp \vec{B}$ and is zero when $\vec{A} \parallel \vec{B}$. We can also interpret the right-hand side of this equation as either the product of the magnitude of vector $\vec{A}$ times the component of $\vec{B}$ perpendicular to $\vec{A}$ or the product of the magnitude of $\vec{B}$ times the component of $\vec{A}$ perpendicular to $\vec{B}$: $\left|\vec{C}\right| = \left|\vec{A}\right| B_{\perp A} = \left|\vec{B}\right| A_{\perp B}$. Either interpretation is valid.

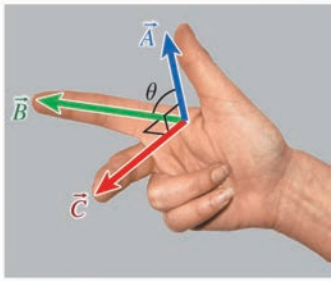

FIGURE 1.27 Vector product.

Mark Dierker/McGraw Hill

The direction of the vector $\vec{C}$ can be found using the right-hand rule: If vector $\vec{A}$ points along the direction of the thumb and vector $\vec{B}$ points along the direction of the index finger, then the vector product is perpendicular to *both* vectors and points along the direction of the middle finger, as shown in Figure 1.27.

It is important to realize that for the vector product, the order of the factors matters:

$$\vec{B} \times \vec{A} = -\vec{A} \times \vec{B}. \tag{1.35}$$

Thus, the vector product differs from both regular multiplication of scalars and multiplication of vectors to form a scalar product.

We'll see immediately from the definition of the vector product that for any vector $\vec{A}$, the vector product with itself is always zero:

$$\vec{A} \times \vec{A} = 0. \tag{1.36}$$

Finally, there is a handy rule for a double vector product involving three vectors: The vector product of the vector $\vec{A}$ with the vector product of the vectors $\vec{B}$ and $\vec{C}$ is the sum of two vectors, one pointing in the direction of the vector $\vec{B}$ and multiplied by the scalar product $\vec{A} \bullet \vec{C}$ and another one pointing in the direction of the vector $\vec{C}$ and multiplied by $-\vec{A} \bullet \vec{B}$:

$$\vec{A} \times \left(\vec{B} \times \vec{C} \right) = \vec{B} \left(\vec{A} \bullet \vec{C} \right) - \vec{C} \left(\vec{A} \bullet \vec{B} \right). \tag{1.37}$$

This *BAC-CAB rule* is straightforward to prove using the Cartesian components in the definitions of the vector product and the scalar product, but the proof is cumbersome and thus omitted here. However, the rule occasionally comes in handy, in particular when dealing with torque and angular momentum. And the mnemonic BAC-CAB makes it fairly easy to remember.

SOLVED PROBLEM 1.3 Hiking

PROBLEM

You are hiking in the Florida Everglades heading southwest from your base camp, for 1.72 km. You reach a river that is too deep to cross; so you make a 90° right turn and hike another 3.12 km to a bridge. How far away are you from your base camp?

SOLUTION

THINK

If you are hiking, you are moving in a two-dimensional plane: the surface of Earth (because the Everglades are flat). Thus, we can use two-dimensional vectors to characterize the various segments of the hike. Making one straight-line hike, then performing a turn, followed by another straight-line hike amounts to a problem of vector addition that is asking for the length of the resultant vector.

SKETCH

Figure 1.28 presents a coordinate system in which the y-axis points north and the x-axis points east, as is conventional. The first portion of the hike, in the southwestern direction, is indicated by the vector $\vec{A}$, and the second portion by the vector $\vec{B}$. The figure also shows the resultant vector, $\vec{C} = \vec{A} + \vec{B}$, for which we want to determine the length.

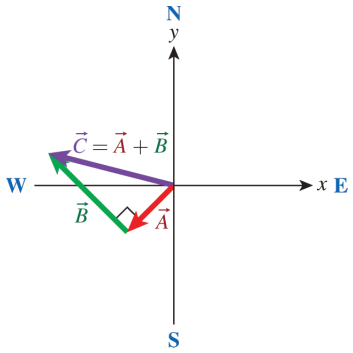

FIGURE 1.28 Hike with a 90° turn.

RESEARCH

If you have drawn the sketch with sufficient accuracy, making the lengths of the vectors in your drawing to be proportional to the lengths of the segments of the hike (as was done in Figure 1.28), then you can measure the length of the vector $\vec{C}$ to determine the distance from your base camp at the end of the second segment of the hike. However, the given distances are specified to three significant digits, so the answer should also have three significant digits. Thus, we cannot rely on the graphical method but must use the component method of vector addition.

In order to calculate the components of the vectors, we need to know their angles relative to the positive x-axis. For the vector $\vec{A}$, which points southwest, this angle is

$\theta_A = 225^\circ$, as shown in Figure 1.29. The vector $\vec{B}$ has an angle of 90° relative to $\vec{A}$, and thus $\theta_B = 135^\circ$ relative to the positive x-axis. To make this point clearer, the starting point of $\vec{B}$ has been moved to the origin of the coordinate system in Figure 1.29. (Remember: We can move vectors around at will. As long as we leave the direction and length of a vector the same, the vector remains unchanged.)

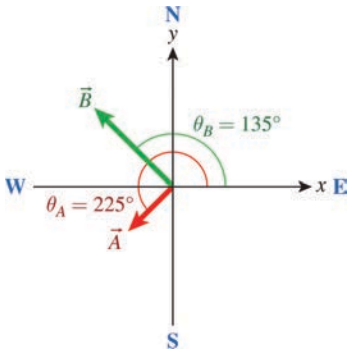

FIGURE 1.29 Angles of the two hike segments.

Now we have everything in place to start our calculation. We have the lengths and directions of both vectors, allowing us to calculate their Cartesian components. Then, we will add their components to calculate the components of the vector $\vec{C}$, from which we can calculate the length of this vector.

SIMPLIFY

The components of the vector $\vec{C}$ are:

$$C_x = A_x + B_x = A\cos\theta_A + B\cos\theta_B$$
$$C_y = A_y + B_y = A\sin\theta_A + B\sin\theta_B.$$

$$C = \sqrt{C_x^2 + C_y^2} = \sqrt{(A_x + B_x)^2 + (A_y + B_y)^2}$$
$$= \sqrt{(A\cos\theta_A + B\cos\theta_B)^2 + (A\sin\theta_A + B\sin\theta_B)^2}.$$

CALCULATE

Now all that is left is to put in the numbers to obtain the vector length:

$$C = \sqrt{((1.72\,\text{km})\cos 225^\circ + (3.12\,\text{km})\cos 135^\circ)^2 + ((1.72\,\text{km})\sin 225^\circ + (3.12\,\text{km}}$$
$$= \sqrt{\left(1.72\cdot\left(-\sqrt{\frac{1}{2}}\right) + 3.12\cdot\left(-\sqrt{\frac{1}{2}}\right)\right)^2 + \left(1.72\cdot\left(-\sqrt{\frac{1}{2}}\right) + 3.12\cdot\sqrt{\frac{1}{2}}\right.}$$

Entering these numbers into a calculator, we obtain:

$$C = 3.562695609\ \text{km}.$$

ROUND

Because the initial distances were given to three significant figures, our final answer should also have (at most) the same precision. Rounding to three significant figures yields our final answer:

$$C = 3.56 \text{ km}.$$

DOUBLE-CHECK

This problem was intended to provide practice with vector concepts. However, if you forget for a moment that the displacements are vectors and note that they form a right triangle, you can immediately calculate the length of side C from the Pythagorean Theorem as follows:

$$C = \sqrt{A^2 + B^2} = \sqrt{1.72^2 + 3.12^2} \text{ km} = 3.56 \text{ km}.$$

Here we also rounded our result to three significant figures, and we see that it agrees with the answer obtained using the longer procedure of vector addition.

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- Large and small numbers can be represented using scientific notation, consisting of a mantissa and a power of ten.
- Physical systems are described by the SI system of units. These units are based on reproducible standards and provide convenient methods of scaling and calculation. The base units of the SI system include meter (m), kilogram (kg), second (s), and ampere (A).
- Physical systems have widely varying sizes, masses, and time scales, but the same physical laws govern all of them.
- A number (with a specific number of significant figures) or a set of numbers (such as components of a vector) must be combined with a unit or units to describe physical quantities.
- Vectors in three dimensions can be specified by their three Cartesian components, $\vec{A} = (A_x, A_y, A_z)$. Each of these Cartesian components is a number.
- Vectors can be added or subtracted. In Cartesian components,
  $\vec{C} = \vec{A} + \vec{B} = (A_x, A_y, A_z) + (B_x, B_y, B_z)$
  $= (A_x + B_x, A_y + B_y, A_z + B_z)$.
- Multiplication of a vector with a scalar results in another vector in the same or opposite direction but of different magnitude,
  $\vec{E} = s\vec{A} = s(A_x, A_y, A_z) = (sA_x, sA_y, sA_z)$.
- Unit vectors are vectors of length 1. The unit vectors in Cartesian coordinate systems are denoted by $\hat{x}$, $\hat{y}$, and $\hat{z}$.
- The length and direction of a two-dimensional vector can be determined from its Cartesian components: $A = \sqrt{A_x^2 + A_y^2}$ and $\theta = \tan^{-1}(A_y/A_x)$.
- The Cartesian components of a two-dimensional vector can be calculated from the vector's length and angle with respect to the x-axis: $A_x = A\cos\theta$ and $A_y = A\sin\theta$.
- The scalar product, or dot product, of two vectors yields a scalar quantity and is defined as $\vec{A} \bullet \vec{B} = A_xB_x + A_yB_y + A_zB_z$.
- The vector product, or cross product, of two vectors yields another vector and is defined as $\vec{A} \times \vec{B} = \vec{C} = (A_yB_z - A_zB_y, A_zB_x - A_xB_z, A_xB_y - A_yB_x)$.

ANSWERS TO SELF-TEST OPPORTUNITIES

1.1 Equation 1.30

$$\widehat{x} \bullet \widehat{x} = (1,0,0) \bullet (1,0,0) = 1 \cdot 1 + 0 \cdot 0 + 0 \cdot 0 = 1$$
$$\hat{y} \bullet \hat{y} = (0,1,0) \bullet (0,1,0) = 0 \cdot 0 + 1 \cdot 1 + 0 \cdot 0 = 1$$
$$\hat{z} \bullet \hat{z} = (0,0,1) \bullet (0,0,1) = 0 \cdot 0 + 0 \cdot 0 + 1 \cdot 1 = 1$$

Equation 1.31

$$\widehat{x} \bullet \hat{y} = (1,0,0) \bullet (0,1,0) = 1 \cdot 0 + 0 \cdot 1 + 0 \cdot\ 0 = 0$$
$$\widehat{x} \bullet \hat{z} = (1,0,0) \bullet (0,0,1) = 1 \cdot 0 + 0 \cdot 0 + 0 \cdot 1 = 0$$
$$\hat{y} \bullet \hat{z} = (0,1,0) \bullet (0,0,1) = 0 \cdot 0 + 1 \cdot 0 + 0 \cdot 1 = 0$$
$$\hat{y} \bullet \widehat{x} = (0,1,0) \bullet (1,0,0) = 0 \cdot 1 + 1 \cdot 0 + 0 \cdot 0 = 0$$
$$\hat{z} \bullet \widehat{x} = (0,0,1) \bullet (1,0,0) = 0 \cdot 1 + 0 \cdot 0 + 1 \cdot 0 = 0$$
$$\hat{z} \bullet \hat{y} = (0,0,1) \bullet (0,1,0) = 0 \cdot 0 + 0 \cdot 1 + 1 \cdot 0 = 0$$

PROBLEM-SOLVING GUIDELINES: NUMBERS, UNITS, AND VECTORS

1. Try to use our seven-step strategy for problem solving, even if you have no idea how to arrive at the final solution. Sometimes the process of making a sketch can give you a hint about what to do next.

2. In general, you should try to convert all given units to SI units before you start working with numbers. Working with quantities in SI units makes computations easier.

3. In most situations, the number of significant figures your final solution should be rounded to is the number of significant figures in the least precisely given quantity.

4. Estimating a solution for a problem can be very useful for obtaining an idea of the order of magnitude of the solution. Often, estimating can be used as a double-check.

5. In working with vectors, you should generally use the Cartesian coordinate system. Make use of your knowledge of trigonometry when solving vector problems!

6. The graphical method for vector addition and subtraction is useful for making sketches. But the component method is more precise, and thus preferred if you have to arrive at a numerical answer.

Multiple-Choice Questions

1.1 Which of the following is the frequency of the musical note C5?

a) 376 g

b) 483 m/s

c) 523 Hz

d) 26.5 J

1.2 If $\vec{A}$ and $\vec{B}$ are vectors and $\vec{B} = -\vec{A}$, which of the following is true?

a) The magnitude of $\vec{B}$ is equal to the negative of the magnitude of $\vec{A}$.

b) $\vec{A}$ and $\vec{B}$ are perpendicular.

c) The direction angle of $\vec{B}$ is equal to the direction angle of $\vec{A}$ plus 180°.

d) $\vec{A} + \vec{B} = 2\vec{A}$.

1.3 Compare three SI units: millimeter, kilogram, and microsecond. Which is the largest?

a) millimeter

b) kilogram

c) microsecond

d) The units are not comparable.

1.4 What is(are) the difference(s) between 3.0 and 3.0000?

a) 3.0000 could be the result from an intermediate step in a calculation; 3.0 has to result from a final step.

b) 3.0000 represents a quantity that is known more precisely than 3.0.

c) There is no difference.

d) They convey the same information, but 3.0 is preferred for ease of writing.

1.5 A speed of 7 mm/μs is equal to _____.

a) 7000 m/s

b) 70 m/s

c) 7 m/s

d) 0.07 m/s

1.6 A hockey puck, whose diameter is approximately 3 inches, is to be used to determine the value of π to three significant figures by carefully measuring its diameter and its circumference. For this calculation to be done properly, the measurements must be made to the nearest _____.

a) hundredth of a mm

b) tenth of a mm

c) mm

d) cm

e) in

1.7 What is the sum of $5.786 \cdot 10^3$ m and $3.19 \cdot 10^4$ m?

a) $6.02 \cdot 10^{23}$ m

b) $3.77 \cdot 10^4$ m

c) $8.976 \cdot 10^3$ m

d) $8.98 \cdot 10^3$ m

1.8 What is the number of carbon atoms in 0.5 nanomoles of carbon? One mole contains $6.02 \cdot 10^{23}$ atoms.

a) $3.2 \cdot 10^{14}$atoms

b) $3.19 \cdot 10^{14}$ atoms

c) $3 \cdot 10^{14}$ atoms

d) $3.2 \cdot 10^{17}$ atoms

e) $3.19 \cdot 10^{17}$ atoms

f) $3 \cdot 10^{17}$ atoms

1.9 The resultant of the two-dimensional vectors (1.5 m, 0.7 m), (−3.2 m, 1.7 m), and (1.2 m, −3.3 m) lies in quadrant _____.

a) I

b) II

c) III

d) IV

1.10 By how much does the volume of a cylinder change if the radius is halved and the height is doubled?

a) The volume is quartered.

b) The volume is cut in half.

c) There is no change in the volume.

d) The volume doubles.

e) The volume quadruples.

1.11 How is the number 0.009834 expressed in scientific notation?

a) $9.834 \cdot 10^4$

b) $9.834 \cdot 10^{-4}$

c) $9.834 \cdot 10^3$

d) $9.834 \cdot 10^{-3}$

1.12 How many significant figures does the number 0.4560 have?

a) five

b) four

c) three

d) two

e) one

1.13 How many watts are in 1 gigawatt (GW)?

a) 10^3

b) 10^6

c) 10^9

d) 10^{12}

e) 10^{15}

1.14 What is the limit of $\gamma = 1/\sqrt{1-(v/c)^2}$, where c is a constant and $v \to 0$?

a) $\gamma = 1$

b) $\gamma = 0$

c) $\gamma = 2$

d) $\gamma = v$

e) $\gamma = {}^{v}/_{2}$

1.15 For the two vectors $\overrightarrow{A} = (2, 1, 0)$ and $\overrightarrow{B} = (0, 1, 2)$, what is their scalar product, $\overrightarrow{A} \bullet \overrightarrow{B}$?

a) 3

b) 6

c) 2

d) 0

e) 1

1.16 For the two vectors $\overrightarrow{A} = (2, 1, 0)$ and $\overrightarrow{B} = (0, 1, 2)$, what is their vector product, $\overrightarrow{A} \times \overrightarrow{B}$?

a) (2, −4, 2)

b) (1, 0, 1)

c) (2, 0, 2)

d) (3, −2, 1)

e) (0, 0, 0)

CONCEPTUAL QUESTIONS

1.17 In Europe, cars' gas consumption is measured in liters per 100 kilometers. In the United States, the unit used is miles per gallon.

a) How are these units related?

b) How many miles per gallon does your car get if it consumes 12.2 liters per 100 kilometers?

c) What is your car's gas consumption in liters per 100 kilometers if it gets 27.4 miles per gallon?

d) Can you draw a curve plotting miles per gallon versus liters per 100 kilometers? If yes, draw the curve.

1.18 If you draw a vector on a sheet of paper, how many components are required to describe it? How many components does a vector in real space have? How many components would a vector have in a four-dimensional world?

1.19 Since vectors in general have more than one component and thus more than one number is used to describe them, they are obviously more difficult to add and subtract than single numbers. Why then work with vectors at all?

1.20 If $\vec{A}$ and $\vec{B}$ are vectors specified in magnitude-direction form, and $\vec{C} = \vec{A} + \vec{B}$ is to be found and to be expressed in magnitude-direction form, how is this done? That is, what is the procedure for adding vectors that are given in magnitude-direction form?

1.21 Suppose you solve a problem and your calculator's display reads 0.0000000036. Why not just write this down? Is there any advantage to using the scientific notation?

1.22 Since the British system of units is more familiar to most people in the United States, why is the international (SI) system of units used for scientific work in the United States?

1.23 Is it possible to add three equal-length vectors and obtain a vector sum of zero? If so, sketch the arrangement of the three vectors. If not, explain why not.

1.24 Is mass a vector quantity? Why or why not?

1.25 Two flies sit exactly opposite each other on the surface of a spherical balloon. If the balloon's volume doubles, by what factor does the distance between the flies change?

1.26 What is the ratio of the volume of a cube of side r to that of a sphere of radius r? Does your answer depend on the particular value of r?

1.27 Consider a sphere of radius r. What is the length of a side of a cube that has the same surface area as the sphere?

1.28 The mass of the Sun is $2 \cdot 10^{30}$ kg, and the Sun contains more than 99% of all the mass in the Solar System. Astronomers estimate there are approximately 100 billion stars in the Milky Way and approximately 100 billion galaxies in the universe. The Sun and other stars are predominantly composed of hydrogen; a hydrogen atom has a mass of approximately $2 \cdot 10^{-27}$kg.

a) Assuming that the Sun is an average star and the Milky Way is an average galaxy, what is the total mass of the universe?

b) Since the universe consists mainly of hydrogen, can you estimate the total number of atoms in the universe?

1.29 A futile task is proverbially said to be "like trying to empty the ocean with a teaspoon." Just how futile is such a task? Estimate the number of teaspoonfuls of water in the Earth's oceans.

1.30 The world's population passed 6.5 billion in 2006. Estimate the amount of land area required if each person were to stand in such a way as to be unable to touch another person. Compare this area to the land area of the United States, 3.5 million square miles, and to the land area of your home state (or country).

1.31 Advances in the field of nanotechnology have made it possible to construct chains of single metal atoms linked one to the next. Physicists are particularly interested in the ability of such chains to conduct electricity with little resistance. Estimate how many gold atoms would be required to make such a chain long enough to wear as a necklace. How many would be required to make a chain that encircled the Earth? If 1 mole of a substance is equivalent to roughly $6.022 \cdot 10^{23}$ atoms, how many moles of gold are required for each necklace?

1.32 One of the standard clichés in physics courses is to talk about approximating a cow as a sphere. How large a sphere makes the best approximation to an average dairy cow? That is, estimate the radius of a sphere that has the same mass and density as a dairy cow.

1.33 Estimate the mass of your head. Assume that its density is that of water, $1000^{\mathrm{kg}}/_{\mathrm{m}^3}$.

1.34 Estimate the number of hairs on your head.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 1.2

1.35 How many significant figures are in each of the following numbers?

a) 4.01

b) 4.010

c) 4

d) 2.00001

e) 0.00001

g) 7.01 · 3.1415

1.36 Two different forces, acting on the same object, are measured. One force is 2.0031 N and the other force, in the same direction, is 3.12 N. These are the only forces acting on the object. Find the total force on the object *to the correct number of significant figures*.

1.37 Three quantities, the results of measurements, are to be added. They are 2.0600, 3.163, and 1.12. What is their sum *to the correct number of significant figures*?

1.38 Given the equation $w = xyz$, and $x = 1.1 \cdot 10^3$, $y = 2.48 \cdot 10^{-2}$, and $z = 6.000$, what is w, in scientific notation and with the correct number of significant figures?

1.39 Write this quantity in scientific notation: one ten-millionth of a centimeter.

1.40 Write this number in scientific notation: one hundred fifty-three million.

Section 1.3

1.41 How many inches are in 30.7484 miles?

1.42 What metric prefixes correspond to the following powers of 10?

a) 10^3

b) 10^{-2}

c) 10^{-3}

1.43 How many millimeters in a kilometer?

1.44 A hectare is a hundred ares, and an are is a hundred square meters. How many hectares are there in a square kilometer?

1.45 The unit of pressure in the SI system is the pascal. What is the SI name for 1 one-thousandth of a pascal?

1.46 The masses of four sugar cubes are measured to be 25.3 g, 24.7 g, 26.0 g, and 25.8 g. Express the answers to the following questions in scientific notation, with standard SI units and an appropriate number of significant figures.

a) If the four sugar cubes were crushed and all the sugar collected, what would be the total mass, in kilograms, of the sugar?

b) What is the average mass, in kilograms, of these four sugar cubes?

•**1.47** What is the surface area of a right cylinder of height 20.5 cm and radius 11.9 cm?

Section 1.4

1.48 You step on your brand-new digital bathroom scale, and it reads 125.4 pounds. What is your mass in kilograms?

1.49 The distance from the center of the Moon to the center of the Earth ranges from approximately 356,000 km to 407,000 km.

a) What is the minimum distance to the Moon in miles?

b) What is the maximum distance to the Moon in miles?

1.50 In Major League Baseball, the pitcher delivers his pitches from a distance of 60 feet, 6 inches from home plate. What is the distance in meters?

1.51 A flea hops in a straight path along a meter stick, starting at 0.7 cm and making successive jumps, which are measured to be 3.2 cm, 6.5 cm, 8.3 cm, 10.0 cm, 11.5 cm, and 15.5 cm. Express the answers to the following questions in scientific notation, with units of meters and an appropriate number of significant figures. What is the total distance covered by the flea in these six hops? What is the average distance covered by the flea in a single hop?

•**1.52** One cubic centimeter of water has a mass of 1 gram. A milliliter is equal to a cubic centimeter. What is the mass, in kilograms, of a liter of water? A metric ton is a thousand kilograms. How many cubic centimeters of water are in a metric ton of water? If a metric ton of water were held in a thin-walled cubical tank, how long (in meters) would each side of the tank be?

•**1.53** The speed limit on a particular stretch of road is 45 miles per hour. Express this speed limit in millifurlongs per microfortnight. A furlong is $\frac{1}{8}$ mile, and a fortnight is a period of 2 weeks.

•**1.54** According to one mnemonic rhyme, "A pint's a pound, the world around." Investigate this statement of equivalence by calculating the weight of a pint of water, assuming that the density of water is 1000. kg/m^3 and that the weight of 1.00 kg of a substance is 2.21 pounds. The volume of 1.00 fluid ounce is 29.6 mL.

Section 1.5

1.55 If the radius of a planet is larger than that of Earth by a factor of 8.7, how much bigger is the surface area of the planet than Earth's?

1.56 If the radius of a planet is larger than that of Earth by a factor of 5.8, how much bigger is the volume of the planet than Earth's?

1.57 What is the maximum distance from which a sailor on top of the mast of ship 1, at 34 m above the ocean's surface, can see another sailor on top of the mast of ship 2, at 26 m above the ocean's surface?

1.58 You are flying in a jetliner at an altitude of 35,000 ft. How far away is the horizon?

1.59 How many cubic inches are in 1.56 barrels of oil?

1.60 A car's gasoline tank has the shape of a right rectangular box with a square base whose sides measure 62 cm. Its capacity is 52 L. If the tank has only 1.5 L remaining, how deep is the gasoline in the tank, assuming the car is parked on level ground?

•**1.61** The volume of a sphere is given by the formula $\frac{4}{3}\pi r^3$, where r is the radius of the sphere. The average density of an object is simply the ratio of its mass to its volume. Using the numerical data found in Table 12.1, express the answers to the following questions in scientific notation, with SI units and an appropriate number of significant figures.

a) What is the volume of the Sun?

b) What is the volume of the Earth?

c) What is the average density of the Sun?

d) What is the average density of the Earth?

•**1.62** A tank is in the shape of an inverted cone, having height h = 2.5 m and base radius r = 0.75 m. If water is poured into the tank at a rate of 15 L/s, how long will it take to fill the tank?

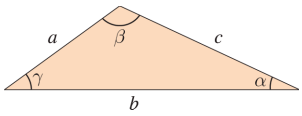
•**1.63** Water flows into a cubical tank at a rate of 15 L/s. If the top surface of the water in the tank is rising by 1.5 cm every second, what is the length of each side of the tank?

••**1.64** The atmosphere has a weight that is, effectively, about 15 pounds for every square inch of Earth's surface. The average density of air at the Earth's surface is about 1.275 kg/m^3. If the atmosphere were uniformly dense (it is not—the density varies quite significantly with altitude), how thick would it be?

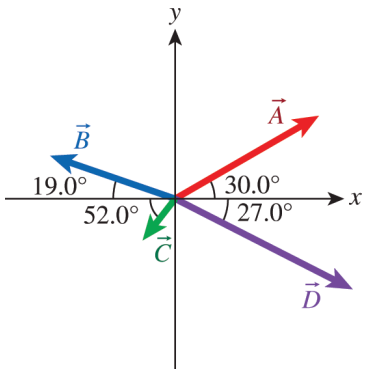
Section 1.6

1.65 A position vector has a length of 40.0 m and is at an angle of 57.0° above the x-axis. Find the vector's components.

1.66 In the triangle shown in the figure, the side lengths are a = 6.6 cm, b = 13.7 cm, and c = 9.2 cm. What is the value of the angle γ? (*Hint:* See Appendix A for the law of cosines.)



1.67 Find the components of the vectors $\vec{A}$, $\vec{B}$, $\vec{C}$, and $\vec{D}$, if their lengths are given by A = 75.0, B = 60.0, C = 25.0, D = 90.0 and their direction angles are as shown in the figure. Write the vectors in terms of unit vectors.



•**1.68** Use the components of the vectors from Problem 1.67 to find

a) the sum $\vec{A} + \vec{B} + \vec{C} + \vec{D}$ in terms of its components

b) the magnitude and direction of the sum $\vec{A} - \vec{B} + \vec{D}$

•**1.69** The Bonneville Salt Flats, located in Utah near the border with Nevada, not far from Interstate I80, cover an area of over 30,000 acres. A race car driver on the Flats first heads north for 4.47 km, then makes a sharp turn and heads southwest for 2.49 km, then makes another turn and heads east for 3.59 km. How far is she from where she started?

•**1.70** A map in a pirate's log gives directions to the location of a buried treasure. The starting location is an old oak tree. According to the map, the treasure's location is found by proceeding 20 paces north from the oak tree and then 30 paces northwest. At this location, an iron pin is sunk in the ground. From the iron pin, walk 10 paces south and dig. How far (in paces) from the oak tree is the spot at which digging occurs?

••**1.71** The next page of the pirate's log contains a set of directions that differ from those on the map in Problem 1.70. These say the treasure's location is found by proceeding 20 paces north from the old oak tree and then 30 paces northwest. After finding the iron pin, one should "walk 12 paces nor'ward and dig downward 3 paces to the treasure box." What is the vector that points from the base of the old oak tree to the treasure box? What is the length of this vector?

••**1.72** The Earth's orbit has a radius of $1.5 \cdot 10^{11}$ m, and that of Venus has a radius of $1.1 \cdot 10^{11}$ m. Consider these two orbits to be perfect circles (though in reality they are ellipses with slight eccentricity). Write the direction and length of a vector from Earth to Venus (take the direction from Earth to Sun to be 0°) when Venus is at the maximum angular separation in the sky relative to the Sun.

••**1.73** A friend walks away from you a distance of 550 m, and then turns (as if on a dime) an unknown angle, and walks an additional 178 m in the new direction. You use a laser range-finder to find out that his final distance from you is 432 m. What is the angle between his initial departure direction and the direction to his final location? Through what angle did he turn? (There are two possibilities.)

Additional Exercises

1.74 The radius of Earth is 6378. km. What is its circumference to three significant figures?

1.75 Estimate the product of 4,308,229 and 44 to one significant figure (show your work and do not use a calculator), and express the result in standard scientific notation.

1.76 Find the vector $\vec{C}$ that satisfies the equation $3\hat{x} + 6\hat{y} - 10\hat{z} + \vec{C} = -7\hat{x} + 14\hat{y}$.

1.77 A position vector has components x = 34.6 m and y = −53.5 m. Find the vector's length and angle with the x-axis.

1.78 For the planet Mars, calculate the distance around the Equator, the surface area, and the volume. The radius of Mars is $3.39 \cdot 10^6$ m.

•**1.79** Find the magnitude and direction of (a) $9\vec{B} - 3\vec{A}$ and (b) $-5\vec{A} + 8\vec{B}$, where $\vec{A}$ = (23.0,59.0), $\vec{B}$ = (90.0,−150.0).

•**1.80** Express the vectors $\vec{A} = (A_x,\ A_y) = (-30.0\text{ m}, -50.0\text{ m})$ and $\vec{B}(B_x,\ B_y) = (30.0\text{ m}, 50.0\text{ m})$ by giving their magnitude and direction as measured from the positive x-axis.

•**1.81** The force F that a spring exerts on you is directly proportional to the distance x that you stretch it beyond its resting length. Suppose that when you stretch a spring 8.00 cm, it exerts a force of 200. N on you. How much force will it exert on you if you stretch it 40.0 cm?

•**1.82** The distance a freely falling object drops, starting from rest, is proportional to the square of the time it has been falling. By what factor will the distance fallen change if the time of falling is three times as long?

•**1.83** A pilot decides to take his small plane for a Sunday afternoon excursion. He first flies north for 155.3 miles, then makes a 90° turn to his right and flies on a straight line for 62.5 miles, then makes another 90° turn to his right and flies 47.5 miles on a straight line.

a) How far away from his home airport is he at this point?

b) In which direction does he need to fly from this point on to make it home in a straight line?

c) What was the farthest distance from the home airport that he reached during the trip?

•**1.84** As the photo shows, during a total eclipse, the Sun and the Moon appear to the observer to be almost exactly the same size. The radii of the Sun and Moon are $r_S = 6.96 \cdot 10^8$ m and $r_M = 1.74 \cdot 10^6$ m, respectively. The distance between the Earth and the Moon is $d_{EM} = 3.84 \cdot 10^8$ m.

Total solar eclipse.

Michael Allen
Siebold/Moment/Getty Images

a) Determine the distance from the Earth to the Sun at the moment of the eclipse.

b) In part (a), the implicit assumption is that the distance from the observer to the Moon's center is equal to the distance between the centers of the Earth and the Moon. By how much is this assumption incorrect, if the observer of the eclipse is on the Equator at noon? [*Hint:* Express this quantitatively, by calculating the relative error as a ratio: (assumed observer-to-Moon distance – actual observer-to-Moon distance)/(actual observer-to-Moon distance).]

c) Use the corrected observer-to-Moon distance to determine a corrected distance from Earth to the Sun.

•**1.85** A hiker travels 1.50 km north and turns to a heading of 20.0° north of west, traveling another 1.50 km along that heading. Subsequently, she then turns north again and travels another 1.50 km. How far is she from her original point of departure, and what is the heading relative to that initial point?

•**1.86** Assuming that 1 mole ($6.02 \cdot 10^{23}$ molecules) of an ideal gas has a volume of 22.4 L at standard temperature and pressure (STP) and that nitrogen, which makes up 78% of the air we breathe, is an ideal gas, how many nitrogen molecules are there in an average 0.5-L breath at STP?

•**1.87** On August 27, 2003, Mars approached as close to Earth as it will for over 50,000 years. If its angular size (the planet's diameter, measured by the angle the radius subtends) on that day was measured by an astronomer to be 24.9 seconds of arc, and its diameter is known to be 6784 km, how close was the approach distance? Be sure to use an appropriate number of significant figures in your answer.

•**1.88** A football field's length is exactly 100 yards, and its width is $53\frac{1}{3}$ yards. A quarterback stands at the exact center of the field and throws a pass to a receiver standing at one corner of the field. Let the origin of coordinates be at the center of the football field and the x-axis point along the longer side of the field, with the y-direction parallel to the shorter side of the field.

a) Write the direction and length of a vector pointing from the quarterback to the receiver.

b) Consider the other three possibilities for the location of the receiver at corners of the field. Repeat part (a) for each.

•**1.89** The circumference of the Cornell Electron Storage Ring is 768.4 m. Express the diameter in inches, to the proper number of significant figures.

••**1.90** Roughly 4% to 5% of what you exhale is carbon dioxide. Assume that 22.4 L is the volume of 1 mole ($6.02 \cdot 10^{23}$ molecules) of carbon dioxide and that you exhale 0.5 L per breath.

a) Estimate how many carbon dioxide molecules you breathe out each day.

b) If each mole of carbon dioxide has a mass of 44.0 g, how many kilograms of carbon dioxide do you exhale in a year?

••1.91 The Earth's orbit has a radius of $1.5 \cdot 10^{11}$ m, and that of Mercury has a radius of $4.6 \cdot 10^{10}$ m. Consider these orbits to be perfect circles (though in reality they are ellipses with slight eccentricity). Write down the direction and length of a vector from Earth to Mercury (take the direction from Earth to Sun to be 0°) when Mercury is at the maximum angular separation in the sky relative to the Sun.

••1.92 The star (other than the Sun) that is closest to Earth is Proxima Centauri. Its distance from Earth can be measured using parallax. *Parallax* is half the apparent angular shift of the star when observed from Earth at points on opposite sides of the Sun. The parallax of Proxima Centauri is 769 milliarcseconds. How far away is Proxima Centauri? (Give your answer in light-years with the correct number of significant digits.)

Multi-Version Exercises

1.93 Write the vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ in Cartesian coordinates.

1.94 Calculate the length and direction of the vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$.

1.95 Add the three vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ graphically.

1.96 Determine the difference vector $\vec{E} = \vec{B} - \vec{A}$ graphically.

1.97 Add the three vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$ using the component method, and find their sum vector $\vec{D}$.

1.98 Use the component method to determine the length of the vector $\vec{F} = \vec{C} - \vec{A} - \vec{B}$.

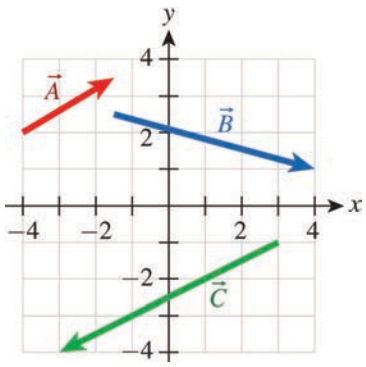


Figure for Problems 1.93 through 1.98

1.99 Sketch the vectors with the components $\vec{A} = (A_x, A_y) = (30.0\text{ m}, -50.0\text{ m})$ and $\vec{B} = (B_x, B_y) = (-30.0\text{ m}, 50.0\text{ m})$, and find the magnitudes of these vectors.

1.100 What angle does $\vec{A} = (A_x, A_y) = (30.0\text{ m}, -50.0\text{ m})$ make with the positive x-axis? What angle does it make with the negative y-axis?

1.101 Sketch the vectors with the components $\vec{A} = (A_x, A_y) = (-30.0\text{ m}, -50.0\text{ m})$ and $\vec{B} = (B_x, B_y) = (30.0\text{ m}, 50.0\text{ m})$, and find the magnitudes of these vectors.

1.102 What angle does $\vec{B} = (B_x, B_y) = (30.0\text{ m}, 50.0\text{ m})$ make with the positive x-axis? What angle does it make with the positive y-axis?

1.103 Find the magnitude and direction of each of the following vectors, which are given in terms of their x- and y-components: $\vec{A} = (23.0, 59.0)$, and $\vec{B} = (90.0, -150.0)$.

1.104 Find the magnitude and direction of $-\vec{A} + \vec{B}$, where $\vec{A} = (23.0, 59.0)$, $\vec{B} = (90.0, -150.0)$.

1.105 Find the magnitude and direction of $-5\vec{A} + \vec{B}$, where $\vec{A} = (23.0, 59.0)$, $\vec{B} = (90.0, -150.0)$.

1.106 Find the magnitude and direction of $-7\vec{B} + 3\vec{A}$, where $\vec{A} = (23.0, 59.0)$, $\vec{B} = (90.0, -150.0)$.

1.107 Which of the six cases shown in the figure has the largest absolute value of the scalar product of the vectors $\vec{A}$ and $\vec{B}$?

1.108 Which of the six cases shown in the figure has the smallest absolute value of the scalar product of the vectors $\vec{A}$ and $\vec{B}$?

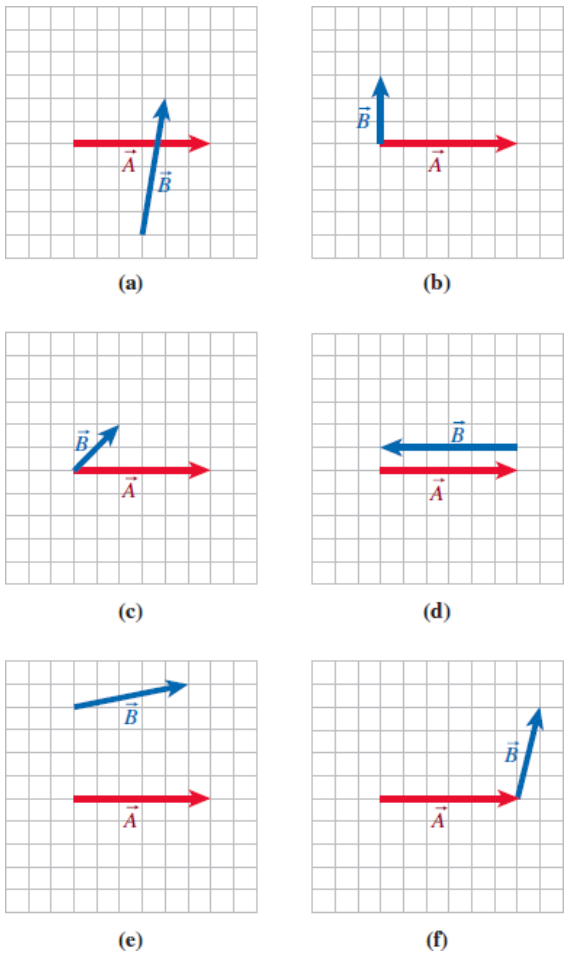

Figure for Problems 1.107 to 1.112

1.109 Which of the six cases shown in the figure has the largest absolute value of the vector product of the vectors $\vec{A}$ and $\vec{B}$?

1.110 Which of the six cases shown in the figure has the smallest absolute value of the vector product of the vectors $\vec{A}$ and $\vec{B}$?

•**1.111** Rank order the six cases shown in the figure from the smallest absolute value to the largest absolute value of the scalar product of the vectors $\vec{A}$ and $\vec{B}$.

•**1.112** Rank order the six cases shown in the figure from the smallest absolute value to the largest absolute value of the vector product of the vectors $\vec{A}$ and $\vec{B}$.

1.113 Toward the end of their lives many stars become much bigger. Assume that they remain spherical in shape and that their masses do not change in this process. If the radius of a star increases by a factor of 11.4, by what factor do (a) its surface area, (b) its circumference, and (c) its volume change?

1.114 Toward the end of their lives many stars become much bigger. Assume that they remain spherical in shape and that their masses do not change in this process. If the circumference of a star increases by a factor of 12.5, by what factor do (a) its surface area, (b) its radius, and (c) its volume change?

1.115 Toward the end of their lives many stars become much bigger. Assume that they remain spherical in shape and that their masses do not change in this process. If the volume of a star increases by a factor of 872, by what factor do (a) its surface area, (b) its circumference, and (c) its diameter change?

•**1.116** Toward the end of their lives many stars become much bigger. Assume that they remain spherical in shape and that their masses do not change in this process. If the surface area of a star increases by a factor of 274, by what factor do (a) its radius, (b) its volume, and (c) its density change?

You can see that the train in Figure 2.1 is moving very fast by noticing that its image is blurred compared with the stationary crossing signal and telephone pole. But can you tell if the train is speeding up, slowing down, or zipping by at constant speed? A photograph can convey an object's speed because the object moves during the exposure time, but a photograph cannot show a change in speed, referred to as acceleration. Yet acceleration is extremely important in physics, at least as important as speed itself.

FIGURE 2.1 A fast-moving train passes a railroad crossing.

VanderWolf Images/Shutterstock

In this chapter, we look at the terms used in physics to describe an object's motion: displacement, velocity, and acceleration. We examine motion along a straight line (one-dimensional motion) in this chapter and motion on a curved path (motion in a plane, or two-dimensional motion) in the next chapter. One of the greatest advantages of physics is that its laws are universal, so the same general terms and ideas apply to a wide range of situations. Thus,

we can use the same equations to describe the flight of a baseball and the lift-off of a rocket into space from Earth to Mars. In this chapter, we will use some of the problem-solving techniques discussed in Chapter 1 along with some new ones.

As you continue in this course, you will see that almost everything moves relative to other objects on some scale or other, whether it is a comet plunging through space at several kilometers per second or the atoms in a seemingly stationary object vibrating millions of times per second. The terms we introduce in this chapter will be part of your study for the rest of the course and afterward.

WHAT WE WILL LEARN

- We will learn to describe the motion of an object traveling in a straight line or in one dimension.
- We will learn to define position, displacement, and distance.
- We will learn to describe motion of an object in a straight line with constant acceleration.
- We will see that an object can be in free fall in one dimension, where it undergoes constant acceleration due to gravity.
- We will define the concepts of instantaneous velocity and average velocity.
- We will define the concepts of instantaneous acceleration and average acceleration.
- We will learn to calculate the position, velocity, and acceleration of an object moving in a straight line.

2.1 Introduction to Kinematics

The study of physics is divided into several large parts, one of which is mechanics. **Mechanics**, or the study of motion and its causes, is usually subdivided. In this chapter and the next, we examine the kinematics aspect of mechanics. **Kinematics** is the study of the motion of objects. These objects may be, for example, cars, baseballs, people, planets, or atoms. For now, we will set aside the question of what causes this motion. We will return to that question when we study forces.

We will also not consider rotation in this chapter, but concentrate on only translational motion (motion without rotation). Furthermore, we will neglect all internal structure of a moving object and consider it to be a point particle, or pointlike object. That is, to determine the equations of motion for an object, we imagine it to be located at a single point in space at each instant of time. What point of an object should we choose to represent its location? Initially, we will simply use the geometric center, the middle. (Chapter 8, on systems of particles and extended objects, will give a more precise definition for the point location of an object, called the *center of mass*.)

Concept Check 2.1

The train in Figure 2.1 is

a) speeding up.

b) slowing down.

c) traveling at a constant speed.

d) moving at a rate that can't be determined from the photo.

2.2 Position Vector, Displacement Vector, and Distance

The simplest motion we can investigate is that of an object moving in a straight line. Examples of this motion include a person running the 100-m dash, a car driving on a straight segment of road, and a stone falling straight down off a cliff. In later chapters, we will consider motion in two or more dimensions and will see that the concepts we derive here for one-dimensional motion still apply.

If an object is located on a particular point on a line, we can denote this point with its **position vector**, as described in Section 1.6. Throughout this book, we use the symbol $\vec{r}$ to denote the position vector. Since we are working with motion in only one dimension in this chapter, the position vector has only one component. If the motion is in the horizontal direction, this one component is the *x*-component. (For motion in the vertical direction, we will use the *y*-component; see Section 2.7.) One number, the *x*-coordinate or *x*-component of the position vector (with a corresponding unit), uniquely specifies the position vector in one-dimensional motion. Some valid ways of writing a position are $x = 4.3$ m, $x = 7\frac{3}{8}$ inches, and $x = -2.04$ km; it is understood that these specifications refer to the *x*-component of the position vector. Note that a position vector's *x*-component can have a positive or a negative value, depending on the location of the point and the axis direction that we choose to be positive. The value of the *x*-component also depends on where we define the origin of the coordinate system—the zero of the straight line.

The position of an object can change as a function of time, *t;* that is, the object can move. We can therefore formally write the position vector in function notation: $\vec{r} = \vec{r}(t)$ In one dimension, this means that the *x*-component of the vector is a function of time,

$x = x(t)$. If we want to specify the position at some specific time t_1 , we use the notation $x_1 \equiv x(t_1)$.

Position Graphs

Before we go any further, let's graph an object's position as a function of time. Figure 2.2a illustrates the principle involved by showing several frames of a video of a car driving down a road. The video frames were taken at time intervals of $\frac{1}{3}$ second.

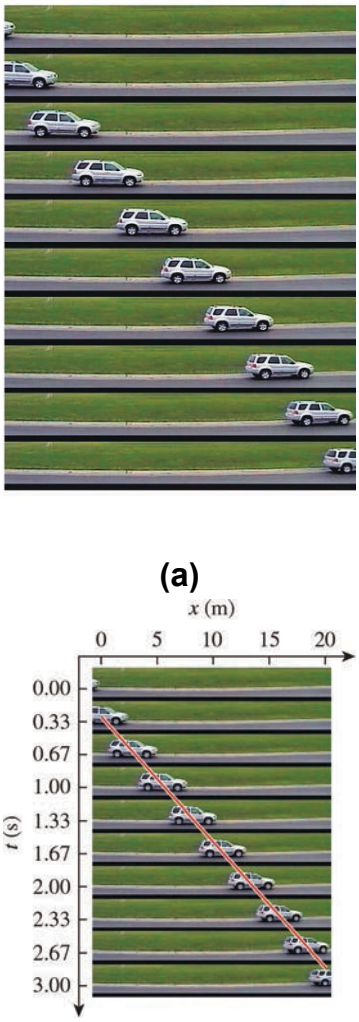

FIGURE 2.2 (a) Series of video frames of a moving car, taken every $\frac{1}{3}$ second; (b) same series, but with a coordinate system and a red line connecting the center of the car in successive frames.

a-b: W. Bauer and G. D. Westfall

We are free to choose the origins of our time measurements and of our coordinate system. In this case, we choose the time of the second frame to be $t = \frac{1}{3}$s and the position of the center of the car in the second frame as $x = 0$. We can now draw our coordinate axes and graph over the frames (Figure 2.2b). The position of the

car as a function of time lies on a straight line. Again, keep in mind that we are representing the car by a single point.

When drawing graphs, it is customary to plot the independent variable—in this case, the time t—on the horizontal axis and to plot x, which is called the dependent variable because its value depends on the value of t, on the vertical axis. Figure 2.3 is a graph of the car's position as a function of time drawn in this customary way. (Note that if Figure 2.2b were rotated 90° counterclockwise and the pictures of the car removed, the two graphs would be the same.)

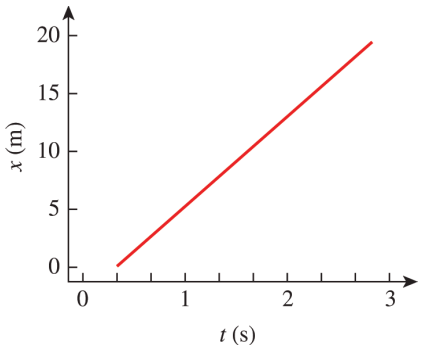

FIGURE 2.3 Same graph as Figure 2.2b, but rotated so that the time axis is horizontal, and without the pictures of the car.

Displacement

Now that we have specified the position vector, let's go one step further and define displacement. **Displacement** is simply the difference between the final position vector, $\overrightarrow{r_2} \equiv \overrightarrow{r}(t_2)$ at the end of a motion and the initial position vector, $\overrightarrow{r_1} \equiv \overrightarrow{r}(t_1)$ We write the displacement vector as

$$\Delta\overrightarrow{r} = \overrightarrow{r_2} - \overrightarrow{r_1}. \qquad \textbf{(2.1)}$$

We use the notation $\Delta\overrightarrow{r}$ for the displacement vector to indicate that it is a difference between two position vectors. Note that the displacement vector is independent of the location of the origin of the coordinate system. Why? Any shift of the coordinate system will add to the position vector $\overrightarrow{r_2}$ the same amount that it adds to the position vector $\overrightarrow{r_1}$ thus, the difference between the position vectors, $\Delta\overrightarrow{r}$, will not change.

Just like the position vector, the displacement vector in one dimension has only an *x*-component, which is the difference between the *x*-components of the final and initial position vectors:

$$\Delta x = x_2 - x_1. \qquad \textbf{(2.2)}$$

Also just like position vectors, displacement vectors can be positive or negative. In particular, the displacement vector $\Delta\overrightarrow{r_{ba}}$ for going from point *a* to point *b* is exactly the negative of $\Delta\overrightarrow{r_{ba}}$ going from point *b* to point *a*:

$$\Delta\overrightarrow{r_{ba}} = \overrightarrow{r_b} - \overrightarrow{r_a} = -\left(\overrightarrow{r_a} - \overrightarrow{r_b}\right) = -\Delta\overrightarrow{r_{ab}}. \qquad \textbf{(2.3)}$$

And it is probably obvious to you at this point that this relationship also holds for the x-component of the displacement vector, $\Delta x_{ba} = x_b - x_a = -(x_a - x_b) = -\Delta x_{ab}$.

Distance

For motion on a straight line without changing directions, the **distance**, ℓ, that a moving object travels is the absolute value of the displacement vector:

$$\ell = \left|\Delta\vec{r}\right|. \qquad \textbf{(2.4)}$$

For one-dimensional motion, this distance is also the absolute value of the x-component of the displacement vector, $\ell = |\Delta x|$. (For multidimensional motion, we calculate the length of the displacement vector as shown in Chapter 1.) The distance is always greater than or equal to zero and is measured in the same units as position and displacement. However, distance is a scalar quantity, not a vector. If the displacement is not in a straight line or if it is not all in the same direction, the displacement must be broken up into segments that are approximately straight and unidirectional, and then the distances for the various segments are added to get the total distance. The following solved problem illustrates the difference between distance and displacement.

Concept Check 2.2

Your dorm room is located 0.25 mile from the Dairy Store. You walk from your room to the Dairy Store and back. Which of the following statements about your trip is true?

a) The distance is 0.50 mile, and the displacement is 0.50 mile.

b) The distance is 0.50 mile, and the displacement is 0.00 mile.

c) The distance is 0.00 mile, and the displacement is 0.50 mile.

d) The distance is 0.00 mile, and the displacement is 0.00 mile.

SOLVED PROBLEM 2.1 Trip Segments

The distance between Des Moines and Iowa City is 170.5 km (106.0 miles) along Interstate 80, and as you can see from the map (Figure 2.4), the route is a straight line to a good approximation. Approximately halfway between the two cities, where I80 crosses highway US63, is the city of Malcom, 89.9 km (55.9 miles) from Des Moines.

FIGURE 2.4 Route I80 between Des Moines and Iowa City.

PROBLEM

If we drive from Malcom to Des Moines and then go to Iowa City, what are the total distance and total displacement for this trip?

SOLUTION

THINK

Distance and displacement are not identical. If the trip consisted of one segment in one direction, the distance would just be the absolute value of the displacement, according to equation 2.4. However, this trip is composed of segments with a direction change, so we need to be careful. We'll treat each segment individually and then add up the segments in the end.

SKETCH

Because I80 is almost a straight line, it is sufficient to draw a straight horizontal line and make this our coordinate axis. We enter the positions of the three cities as x_{I} (Iowa City), x_{M} (Malcom), and x_{D} (Des Moines). We always have the freedom to define the origin of our coordinate system, so we elect to put it at Des Moines, thus setting $x_{\mathrm{D}} = 0$. As is conventional, we

define the positive direction to the right, in the eastward direction. See Figure 2.5.

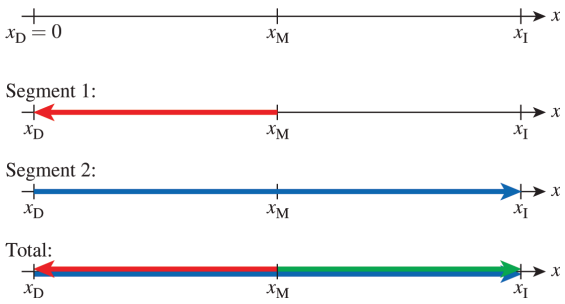

FIGURE 2.5 Coordinate system and trip segments for the Malcom to Des Moines to Iowa City trip.

We also draw arrows for the displacements of the two segments of the trip. We represent segment 1 from Malcom to Des Moines by a red arrow, and segment 2 from Des Moines to Iowa City by a blue arrow. Finally, we draw a diagram for the total trip as the sum of the two trips.

RESEARCH

With our assignment of $x_D = 0$, Des Moines is the origin of the coordinate system. According to the information given us, Malcom is then at $x_M = +89.9$ km and Iowa City is at $x_I = +170.5$ km. Note that we write a plus sign in front of the numbers for x_M and x_I to remind us that these are components of position vectors and can have positive or negative values.

For the first segment, the *displacement* is given by

$$\Delta x_1 = x_D - x_M.$$

Thus, the distance driven for this segment is

$$\ell_1 = |\Delta x_1| = |x_D - x_M|.$$

In the same way, the displacement and distance for the second segment are

$$\Delta x_2 = x_\mathrm{I} - x_\mathrm{D}$$
$$\ell_2 = |\Delta x_2| = |\mathrm{x_I} - \mathrm{x_D}|.$$

For the sum of the two segments, the total trip, we use simple addition to find the displacement,

$$\Delta x_\mathrm{total} = \Delta x_1 + \Delta x_2,$$

and the total distance,

$$\ell_\mathrm{total} = \ell_1 + \ell_2.$$

SIMPLIFY

We can simplify the equation for the total displacement a little bit by inserting the expressions for the displacements for the two segments:

$$\begin{aligned}\Delta x_\mathrm{total} &= \Delta x_1 + \Delta x_2 \\ &= (\mathrm{x_D} - \mathrm{x_M}) + (x_\mathrm{I} - x_\mathrm{D}) \\ &= x_\mathrm{I} - \mathrm{x_M}.\end{aligned}$$

This is an interesting result—for the total displacement of the entire trip, it does not matter at all that we went to Des Moines. All that matters is where the trip started and where it ended. The total displacement is a result of a one-dimensional vector addition, as indicated in the bottom part of Figure 2.5 by the green arrow.

CALCULATE

Now we can insert the numbers for the positions of the three cities in our coordinate system. We then obtain for the net displacement in our trip

$$\Delta x_\mathrm{total} = x_\mathrm{I} - x_\mathrm{M} = (+170.5\ \mathrm{km}) - (+89.9\ \mathrm{km}) = +8($$

For the total distance driven, we get

$$\ell_{\text{total}} = |89.9 \text{ km}| + |170.5 \text{ km}| = 260.4 \text{ km}.$$

(Remember, the distance between Des Moines and Malcom, or Δx_1 and that between Des Moines and Iowa City, or Δx_2, were given in the problem; so we do not have to calculate them again from the differences in the position vectors of the cities.)

ROUND

The numbers for the distances were initially given to a tenth of a kilometer. Since our entire calculation only amounted to adding or subtracting these numbers, it is not surprising that we end up with numbers that are also accurate to a tenth of a kilometer. No further rounding is needed.

DOUBLE-CHECK

As is customary, we first make sure that the units of our answer came out properly. Since we are looking for quantities with the dimension of length, it is comforting that our answers have the units of kilometers. At first sight, it may be surprising that the net displacement for the trip is only 80.6 km, much smaller than the total distance traveled. This is a good time to recall that the relationship between the absolute value of the displacement and the distance (equation 2.4) is valid only if the moving object does *not* change direction (but it did in this example).

This discrepancy is even more apparent for a round trip. In that case, the total distance driven is twice the distance between the two cities, but the total displacement is zero, because the starting point and the end point of the trip are identical.

Self-Test Opportunity 2.1

Suppose we had chosen to put the origin of the coordinate system in Solved Problem 2.1 at Malcom instead of Des Moines. Would the final result of our calculation change? If yes, how? If no, why not?

This result is a general one: If the initial and final positions are the same, the total displacement is 0. As straightforward as this seems for the trip example, it is a potential pitfall in many exam questions. You need to remember that displacement is a vector, whereas distance is a positive scalar.

2.3 Velocity Vector, Average Velocity, and Speed

Not only do distance (a scalar) and displacement (a vector) mean different things in physics, but their rates of change with time are also different. Although the words “speed” and “velocity” are often used interchangeably in everyday speech, in physics “speed” refers to a scalar and “velocity” to a vector.

We define v_x, the x-component of the velocity vector, as the change in position (i.e., the displacement component) in a given time interval divided by that time interval, $\Delta x/\Delta t$. Velocity can change from moment to moment. The velocity calculated by taking the ratio of displacement per time interval is the average of the velocity over this time interval, or the x-component of the **average velocity**, v_x:

$$v_x = \frac{\Delta x}{\Delta t}. \qquad \textbf{(2.5)}$$

Notation: A bar above a symbol is the notation for averaging over a finite time interval.

In calculus, a time derivative is obtained by taking a limit as the time interval approaches zero. We use the same concept here to define the **instantaneous velocity**, usually referred to simply as the **velocity**, as the time derivative of the displacement. For the x-component of the velocity vector, this implies

$$v_x = \lim_{\Delta t \to 0} v_x = \lim_{\Delta \mathrm{t} \to 0} \frac{\Delta x}{\Delta t} \equiv \frac{dx}{dt}. \qquad \textbf{(2.6)}$$

We can now introduce the velocity vector, $\overrightarrow{v}$, as the vector for which each component is the time derivative of the corresponding component of the position vector,

$$\overrightarrow{v} = \frac{d\overrightarrow{r}}{dt}, \qquad \textbf{(2.7)}$$

with the understanding that the derivative operation applies to each of the components of the vector. In the one-dimensional case, this velocity vector $\overrightarrow{v}$ has only an *x*-component, v_x, and the velocity is equivalent to a single velocity component in the spatial *x*-direction.

Figure 2.6 presents three graphs of the position of an object with respect to time. Figure 2.6a shows that we can calculate the average velocity of the object by finding the change in position of the object between two points and dividing by the time it takes to go from x_1 to x_2. That is, the average velocity is given by the displacement, Δx_1, divided by the time interval, Δt_1, or $v_1 = {}^{\Delta x_1}/_{\Delta t_1}$. In Figure 2.6b, the average velocity, $v_2 = {}^{\Delta x_2}/_{\Delta t_2}$, is determined over a smaller time interval, Δt_2. In Figure 2.6c, the instantaneous velocity, $v(t_3) = dx|dt|_{t=t_3}$, is represented by the slope of the blue line tangent to the red curve at $t = t_3$.

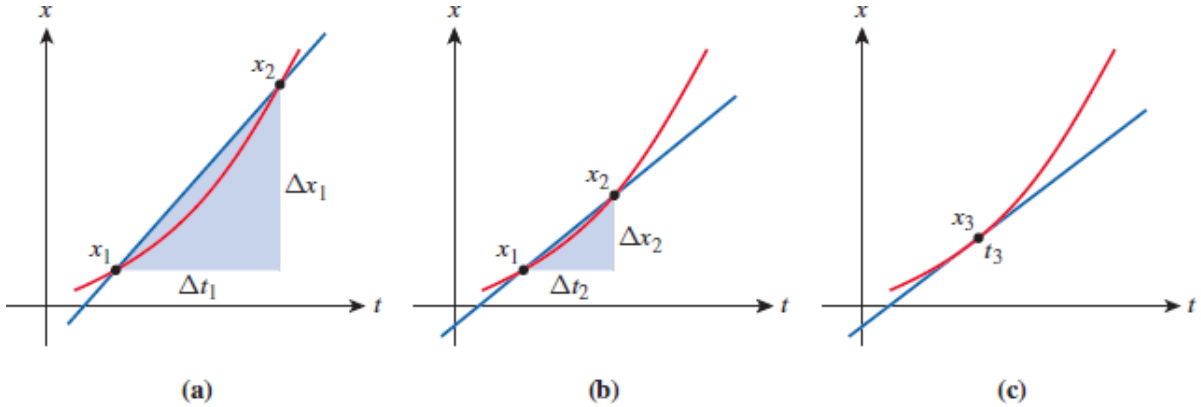

FIGURE 2.6 Instantaneous velocity as the limit of the ratio of displacement to time interval: (a) an average velocity over a large time interval; (b) an average velocity over a smaller time interval; and (c) the instantaneous velocity at a specific time, t_3.

Velocity is a vector, pointing in the same direction as the vector of the infinitesimal displacement, dx. Because the position $x(t)$ and the displacement $\Delta x(t)$ are functions of time, so is the velocity. Because the velocity vector is defined as the time derivative of the displacement vector, all the rules of differentiation introduced in calculus hold. If you need a refresher, consult Appendix A.

EXAMPLE 2.1 Time Dependence of Velocity

PROBLEM

During the time interval from 0.0 to 10.0 s, the position vector of a car on a road is given by $x(t) = a + bt + ct^2$, with $a = 17.2\ \text{m}, b = -10.1\ \text{m/s}$, and $c = 1.10\ \text{m/s}^2$. What is the car's velocity as a function of time? What is the car's average velocity during this interval?

SOLUTION

According to the definition of velocity in equation 2.6, we simply take the time derivative of the position vector function to arrive at our solution:

$$v_x = \frac{dx}{dt} = \frac{d}{dt}\left(a + bt + ct^2\right) = b + 2ct = -10.1\ \text{m/s} +$$

It is instructive to graph this solution. In Figure 2.7, the position as a function of time is shown in blue, and the velocity as a function of time is shown in red. Initially, the velocity has a value of –10.1 m/s, and at $t = 10$ s, the velocity has a value of +11.9 m/s.

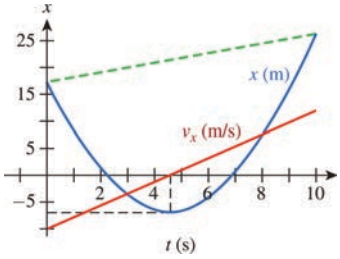

FIGURE 2.7 Graph of the position x and velocity v_x as a function of the time t. The slope of the dashed line represents the average velocity for the time interval from 0 to 10 s.

Note that the velocity is initially negative, is zero at 4.59 s (indicated by the vertical dashed line in Figure 2.7), and then is positive after 4.59 s. At t = 4.59 s, the position graph $x(t)$ shows an extremum (a minimum in this case), just as expected from calculus, since

$$\frac{dx}{dt} = b + 2ct_0 = 0 \Rightarrow t_0 = -\frac{b}{2c} = \frac{-10.1\ \text{m/s}}{2.20\ \text{m/s}^2} = 4.59$$

From the definition of average velocity, we know that to determine the average velocity during a time interval, we need to subtract the position at the beginning of the interval from the position at the end of the interval. By inserting $t = 0$ and $t = 10$ s into the equation for the position vector as a function of time, we obtain $x(t = 0) = 17.2$ m and $\mathrm{x}(t = 10\ s) = 26.2$ m. Therefore,

$$\Delta x = x(t = 10) - x(t = 0) = 26.2\ \text{m} - 17.2\ \text{m} = 9.0\ \text{m}$$

We then obtain for the average velocity over this time interval:

$$\overrightarrow{v}_x = \frac{\Delta x}{\Delta t} = \frac{9.0 \text{ m}}{10 \text{ s}} = 0.90 \text{ m/s}.$$

The slope of the green dashed line in Figure 2.7 is the average velocity over this time interval.

Speed

Speed is the absolute value of the velocity vector. For a moving object, speed is always positive. *Speed* and *velocity* are used interchangeably in everyday contexts, but in physical terms they are very different. Velocity is a vector, which has a direction. For one-dimensional motion, the velocity vector can point in either the positive or the negative direction; in other words, its component can have either sign. Speed is the absolute magnitude of the velocity vector and is thus a scalar quantity:

$$\text{speed} \equiv v = \left| \vec{v} \right| = |v_x|. \qquad \textbf{(2.8)}$$

The last part of this equation makes use of the fact that the velocity vector has only an *x*-component for one-dimensional motion.

In everyday experience, we recognize that speed can never be negative: Speed limits are always posted as positive numbers, and the radar monitors that measure the speed of passing cars also always display positive numbers (Figure 2.8).

FIGURE 2.8
Measuring the speeds of passing cars.

Ted Foxx/Alamy Stock Photo

Earlier, distance was defined as the absolute value of displacement for each straight-line segment *in which the movement does not reverse direction* (see the discussion following equation 2.4). The average speed when a distance ℓ is traveled during a time interval Δt is

$$\text{average speed} \equiv v = \frac{\ell}{\Delta t}. \qquad \textbf{(2.9)}$$

Concept Check 2.3

The speedometer in your car shows

a) average speed.

b) instantaneous speed.

c) average displacement.

d) instantaneous displacement.

EXAMPLE 2.2 Speed and Velocity

Suppose a swimmer completes the first 50 m of the 100-m freestyle in 38.2 s. Once she reaches the far side of the 50-m-long pool, she turns around and swims back to the start in 42.5 s.

PROBLEM

What are the swimmer's average velocity and average speed for (a) the leg from the start to the far side of the pool, (b) the return leg, and (c) the total lap?

SOLUTION

We start by defining our coordinate system, as shown in Figure 2.9. The positive x-axis points toward the bottom of the page.

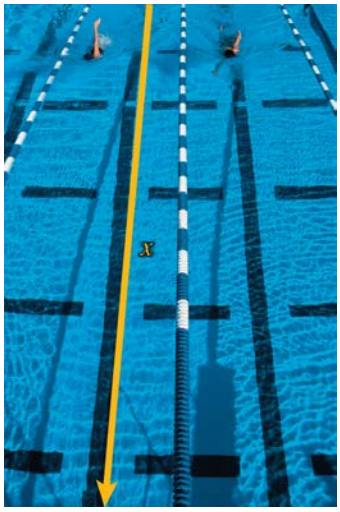

FIGURE 2.9
Choosing an x-axis in a swimming pool.

Ryan McVay/Getty Images

(a) *First leg of the swim:*

The swimmer starts at $x_1 = 0$ and swims to $x_2 = 50$ m. It takes her $\Delta t = 38.2\ s$ s to accomplish this leg. Her average velocity for leg 1 then, according to our definition, is

$$v_{x1} = \frac{x_2 - x_1}{\Delta t} = \frac{50\ \text{m} - 0\ \text{m}}{38.2\ \text{s}} = \frac{50}{38.2}\text{m/s} = 1.31\ \text{m/s}$$

Her average speed is the distance divided by time interval, which, in this case, is the same as the absolute value of her average velocity, or $|v_{x1}| = 1.31\ \text{m/s}$.

(b) *Second leg of the swim:*
We use the same coordinate system for leg 2 as for leg 1. This choice means that the swimmer starts at $x_1 = 50$ m and finishes at $x_2 = 0$, and it takes $\Delta t = 42.5$ s to complete this leg. Her average velocity for this leg is

$$v_{x2} = \frac{x_2 - x_1}{\Delta t} = \frac{0\ \text{m} - 50\ \text{m}}{42.5\ \text{s}} = \frac{-50}{42.5}\text{m/s} = -1.18\ \text{m}$$

Note the negative sign for the average velocity for this leg. The average speed is again the absolute magnitude of the average velocity, or $|v_{x2}| = |-1.18\ \text{m/s}| = 1.18\ \text{m/s}$.

(c) *The entire lap:*
We can find the average velocity in two ways, demonstrating that they result in the same answer. First, because the swimmer started at $x_1 = 0$ and finished at $x_2 = 0$, the difference is 0. Thus, the net displacement is 0, and consequently the average velocity is also 0.

We can also find the average velocity for the whole lap by taking the time-weighted sum of the components of the average velocities of the individual legs:

$$v_x = \frac{v_{x1} \cdot \Delta t_1 + v_{x2} \cdot \Delta t_2}{\Delta t_1 + \Delta t_2} = \frac{(1.31\ \text{m/s})(38.2\ \text{s}) + (-1.}{(38.2\ s) + (42}$$

What do we find for the average speed? The average speed, according to our definition, is the total distance divided by the total time. The total distance is 100 m and the total time is 38.2 s plus 42.5 s, or 80.7 s. Thus,

$$v = \frac{\ell}{\Delta t} = \frac{100\ \text{m}}{80.7\ \text{s}} = 1.24\ \text{m/s}.$$

We can also use the time-weighted sum of the average speeds, leading to the same result. Note that the average speed for the entire lap is between that for leg 1 and that for leg 2. It is not exactly halfway between these two values, but is closer to the lower value because the swimmer spent more time completing leg 2.

2.4 Acceleration Vector

Just as the average velocity is defined as the displacement per time interval, the *x*-component of **average acceleration** is defined as the velocity change per time interval:

$$a_x = \frac{\Delta v_x}{\Delta t}. \tag{2.10}$$

Similarly, the *x*-component of the **instantaneous acceleration** is defined as the limit of the average acceleration as the time interval approaches 0:

$$a_x = \lim_{\Delta t \to 0} a_x = \lim_{\Delta t \to 0} \frac{\Delta v_x}{\Delta t} \equiv \frac{dv_x}{dt}. \tag{2.11}$$

We can now define the acceleration vector as

$$\vec{a} = \frac{d\vec{v}}{dt}, \tag{2.12}$$

where again the derivative operation is understood to act component-wise, just as in the definition of the velocity vector.

Concept Check 2.4

Average acceleration is defined as the

a) displacement change per time interval.

b) position change per time interval.

c) velocity change per time interval.

d) speed change per time interval.

Concept Check 2.5

When you're driving a car along a straight road, you may be traveling in the positive or negative direction and you may have a positive acceleration or a negative acceleration. Match the following combinations of velocity and acceleration with the list of outcomes.

a) positive velocity, positive acceleration

b) positive velocity, negative acceleration

c) negative velocity, positive acceleration

d) negative velocity, negative acceleration

1) slowing down in positive direction

2) speeding up in negative direction

3) speeding up in positive direction

4) slowing down in negative direction

Concept Check 2.6

An example of one-dimensional motion with constant acceleration is

a) the motion of a car during a NASCAR race.

b) the Earth orbiting the Sun.

c) an object in free fall.

d) None of the above describe one-dimensional motion with constant acceleration.

Figure 2.10 illustrates this relationship among velocity, time interval, average acceleration, and instantaneous acceleration as the limit of the average acceleration (for a decreasing time interval). In Figure 2.10a, the average acceleration is given by the velocity change, Δv_1, divided by the time interval $\Delta t_1 : a_1 = {}^{\Delta v_1}/_{\Delta t_1}$. In Figure 2.10b, the average acceleration is determined over a smaller time interval, Δv_2. In Figure 2.10c, the instantaneous acceleration, $a(t_3) = dv/dt|_{t=t_3}$, is represented by the slope of the blue line tangent to the red curve at $t = t_3$. Figure 2.10 looks very similar to Figure 2.6, and this is not a coincidence. The similarity emphasizes that the mathematical operations and physical relationships that connect the velocity and acceleration vectors are the same as those that connect the position and velocity vectors.

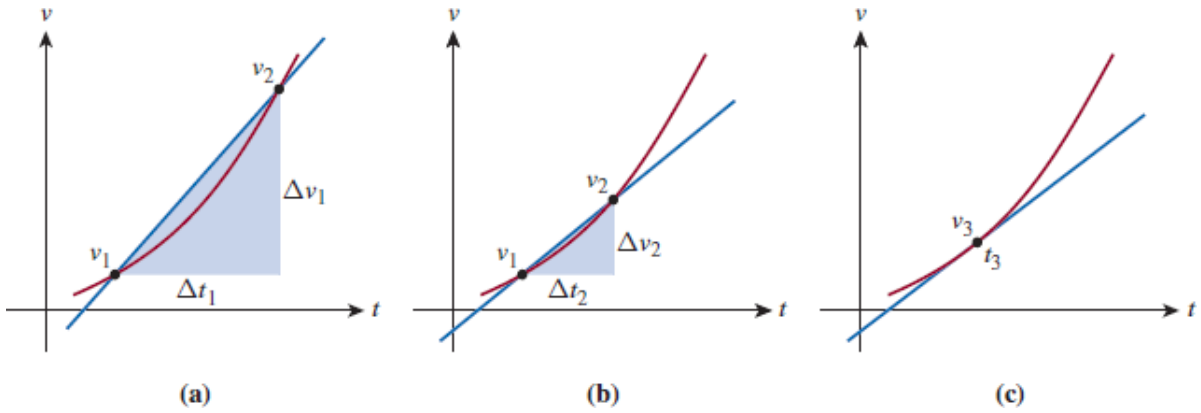

FIGURE 2.10 Instantaneous acceleration as the limit of the ratio of velocity change to time interval: (a) average acceleration over a large time interval; (b) average acceleration over a smaller time interval; and (c) instantaneous acceleration in the limit as the time interval goes to zero.

The acceleration is the time derivative of the velocity, and the velocity is the time derivative of the displacement. The acceleration is therefore the second derivative of the displacement:

$$a_x = \frac{d}{dt}v_x = \frac{d}{dt}\left(\frac{d}{dt}x\right) = \frac{d^2}{dt^2}x. \qquad \textbf{(2.13)}$$

There is no word in everyday language for the absolute value of the acceleration.

Note that we often refer to the *deceleration* of an object as a decrease in the speed of the object over time, which corresponds to acceleration in the opposite direction of the motion of the object.

In one-dimensional motion, an acceleration, which is a change in velocity, necessarily entails a change in the magnitude of the velocity—that is, the speed. However, in the next chapter, we will consider motion in more than one spatial dimension, where the velocity vector can also change its direction, not just its magnitude. In Chapter 9, we will examine motion in a circle with constant speed; in that case, there is a constant acceleration that keeps the object on a circular path but leaves the speed constant.

As Concept Check 2.5 shows, even in one dimension, a positive acceleration does not necessarily mean speeding up and a negative acceleration does not mean that an object must be slowing down. Rather, the combination of velocity and acceleration determines the motion. *If the velocity and acceleration are in the same direction, the object moves faster; if they are in opposite directions, it slows down.* We will examine this relationship further in the next chapter.

2.5 Computer Solutions and Difference Formulas

In some situations, the acceleration changes as a function of time, but the exact functional form is not known beforehand. However, we can still calculate velocity and acceleration even if the position is known only at certain points in time. The following example illustrates this procedure.

EXAMPLE 2.3 World Record for the 100-m Dash

In the 1991 Track and Field World Championships in Tokyo, Japan, Carl Lewis of the United States set a new world record in the 100-m dash. Figure 2.11 lists the times at which he arrived at the 10-m mark, the 20-m mark, and so on, as well as values for his average velocity and average acceleration, calculated from the formulas in equations 2.5 and 2.10. From Figure 2.11, it is clear that after about 3 s, Lewis reached an approximately constant average velocity between 11 and 12 m/s.

t(s)	x(m)	$\bar{v}_x$(m/s)	$\bar{a}_x$(m/s^2)
0.00	0		
		5.32	
1.88	10		5.66
		9.26	
2.96	20		2.66
		10.87

7.30	70		0.17
		12.05	
8.13	80		0.17
		11.49	
9.00	90		−0.65
		11.49	
9.87	100		0.00

FIGURE 2.11
Time, position, average velocity, and average acceleration during Carl Lewis's world record 100-m dash.

Figure 2.11 also indicates how the values for average velocity and average acceleration were obtained. Take, for example, the upper two green boxes, which contain the times and positions for two measurements. From these we get $\Delta t = 2.96\ \text{s} - 1.88\ \text{s} = 1.08\ \text{s}$ and $\Delta x = 20\ \text{m} - 10\ \text{m} = 10\ \text{m}$. The average velocity in this time interval is then $v = \Delta x/\Delta t = 10\ \text{m}/1.08\ \text{s} = 9.26\ \text{m/s}$. We have rounded this result to three significant digits, because the

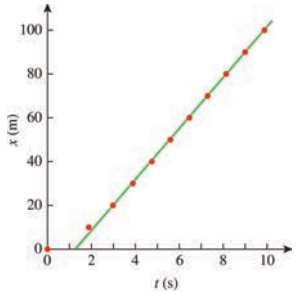
times were given to that accuracy. The accuracy for the distances can be assumed to be even better, because these data were extracted from video analysis that showed the times at which Lewis crossed marks on the ground.

In Figure 2.11 the calculated average velocity is positioned halfway between the lines for time and distance, indicating that it is a good approximation for the instantaneous velocity in the middle of the time interval.

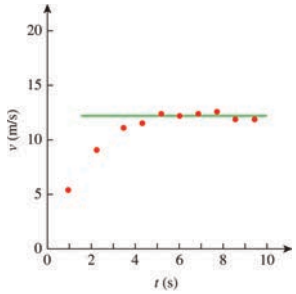
The average velocities for other time intervals were obtained in the same way. Using the numbers in the second and third green boxes in Figure 2.11, we obtained an average velocity of 10.87 m/s for the time interval from 2.96 s to 3.88 s. With two velocity values, we can use the difference formula for the acceleration to calculate the average acceleration. Here we assume that the instantaneous velocity at a time corresponding to halfway between the first two green boxes (2.42 s) is equal to the average velocity during the interval between the first two green boxes, or 9.26 m/s. Similarly, we take the instantaneous velocity at 3.42 s (midway between the second and third boxes) to be 10.87 m/s. Then, the average acceleration between 2.42 s and 3.42 s is

$$a_x = \Delta v_x/\Delta t = (10.87\ \text{m/s} - 9.26\ \text{m/s})/(3.42\ \text{s} - 2.42$$

From the entries in Figure 2.11 obtained in this way, we can see that Lewis did most of his accelerating between the start of the race and the 30-m mark, where he attained his maximum velocity between 11 and 12 m/s. He then ran with about that velocity until he reached the finish line. This result is clearer in a graphical display of his position versus time during the race (Figure 2.12a). The red dots represent the data points from Figure 2.11, and the green straight line represents a constant velocity of 11.58 m/s. In Figure 2.12b, Lewis's velocity is plotted as a function of time. The green line again represents a constant velocity of 11.58 m/s, fitted to the last six points, where Lewis is no longer accelerating but running at a constant velocity.



(a)



(b)

FIGURE 2.12
Analysis of Carl Lewis's 100-m dash in 1991: (a) his position as a function of time; (b) his velocity as a function of time.

The type of numerical analysis that treats average velocities and accelerations as approximations for the instantaneous values of these quantities is very common in all types of scientific and engineering applications. It is indispensable in situations where the precise functional dependencies on time are not known and researchers must rely on numerical approximations for derivatives obtained via the difference formulas. Most practical solutions of scientific and engineering problems found with the aid of computers make use of difference formulas such as those introduced here.

The entire field of numerical analysis is devoted to finding better numerical approximations that will enable more precise and

faster computer calculations and simulations of natural processes. Difference formulas similar to those introduced here are as important for the everyday work of scientists and engineers as the calculus-based analytic expressions. This importance is a consequence of the computer revolution in science and technology, which, however, does not make the contents of this textbook any less important. In order to devise a valid solution to an engineering or science problem, you have to understand the basic underlying physical principles, no matter what calculation techniques you use. This fact is well recognized by cutting-edge movie animators and creators of special digital effects, who have to take basic physics classes to ensure that the products of their computer simulations look realistic to the audience.

2.6 Finding Displacement and Velocity from Acceleration

The fact that integration is the inverse operation of differentiation is known as the *Fundamental Theorem of Calculus*. It allows us to reverse the differentiation process leading from displacement to velocity to acceleration and instead integrate the equation for velocity (2.6) to obtain displacement and the equation for acceleration (2.13) to obtain velocity. Let's start with the equation for the *x*-component of the velocity:

$$v_x(t) = \frac{dx(t)}{dt} \Rightarrow$$

$$\int_{t_0}^{t} v_x(t')dt' = \int_{t_0}^{t} \frac{dx(t')}{dt'}dt' = x(t) - x(t_0) \Rightarrow \quad \textbf{(2.14)}$$

$$x(t) = x_0 + \int_{t_0}^{t} v_x(t')dt'.$$

Notation: Here again we have used the convention that $x(t_0) = x_0$, the initial position. Further, we have used the notation t' in the definite integrals in equation 2.14. This prime notation reminds us that the integration variable is a dummy variable, which serves to identify the physical quantity we want to integrate. Throughout this book, we will reserve the prime notation for dummy integration variables in definite integrals. (Note that some books use a prime to denote a spatial derivative, but to avoid possible confusion, this book will not do so.)

In the same way, we integrate equation 2.13 for the x-component of the acceleration to obtain an expression for the x-component of the velocity:

$$a_x(t) = \frac{dv_x(t)}{dt} \Rightarrow$$
$$\int_{t_0}^{t} a_x(t')dt' = \int_{t_0}^{t} \frac{dv_x(t')}{dt'}dt' = v_x(t) - v_x(t_0) \Rightarrow \quad \textbf{(2.15)}$$
$$v_x(t) = v_{x0} + \int_{t_0}^{t} a_x(t')dt'.$$

Here $v_x(t_0) = v_{x0}$ is the initial velocity component in the x-direction. Just like the derivative operation, integration is understood to act component-wise, so we can write the integral relationships for the vectors from those for the components in equations 2.14 and 2.15. Formally, we then have

$$\vec{r}(t) = \vec{r_0} + \int_{t_0}^{t} \vec{v}(t')dt' \quad \textbf{(2.16)}$$

and

$$\vec{v}(t) = \vec{v_0} + \int_{t_0}^{t} \vec{a}(t')dt'. \quad \textbf{(2.17)}$$

This result means that for any given time dependence of the acceleration vector, we can calculate the velocity vector, provided we are given the initial value of the velocity vector. We can also

calculate the displacement vector, if we know its initial value and the time dependence of the velocity vector.

In calculus, you probably learned that the geometrical interpretation of the definite integral is an area under a curve. This is true for equations 2.14 and 2.15. We can interpret the area under the curve of $v_x(t)$ between t_0 and t as the difference in the position between these two times, as shown in Figure 2.13a. Figure 2.13b shows that the area under the curve of $a_x(t)$ in the time interval between t_0 and t is the velocity difference between these two times.

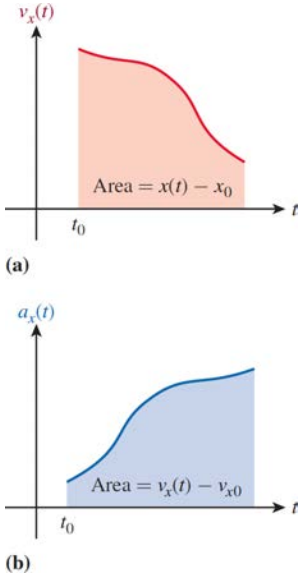


FIGURE 2.13 Geometrical interpretation of the integrals of (a) velocity and (b) acceleration with respect to time.

2.7 Motion with Constant Acceleration

In many physical situations, the acceleration experienced by an object is approximately, or perhaps even exactly, constant. We can derive useful equations for these special cases of motion with constant acceleration. If the acceleration, a_x, is a constant, then the time integral used to obtain the velocity in equation 2.15 results in

$$v_x(t) = v_{x0} + \int_0^t a_x dt' = v_{x0} + ax \int_0^t dt' \Rightarrow \quad \textbf{(2.18)}$$
$$v_x(t) = v_{x0} + a_x t,$$

where we have taken the lower limit of the integral to be $t_0 = 0$ for simplicity. This means that the velocity is a linear function of time.

$$x = x_0 + \int_0^t v_x(t')dt' = x_0 + \int_0^t (v_{x0} + a_x t')dt'$$
$$= x_0 + v_{x0}\int_0^t dt' + a_x \int_0^t t' dt' \Rightarrow \quad \textbf{(2.19)}$$
$$x(t) = x_0 + v_{x0}t + \tfrac{1}{2}a_x t^2.$$

Thus, with a constant acceleration, the velocity is always a linear function of time, and the position is a quadratic function of time. Three other useful equations can be derived using equations 2.18 and 2.19 as starting points. After listing these three equations, we'll work through their derivations.

The average velocity in the time interval from 0 to t is the average of the velocities at the beginning and end of the time interval:

$$v_x = \tfrac{1}{2}(v_{x0} + v_x). \qquad \textbf{(2.20)}$$

The average velocity from equation 2.20 leads to an alternative way to express the position:

$$x = x_0 + v_x t. \qquad \textbf{(2.21)}$$

Finally, we can write an equation for the square of the velocity that does not contain the time explicitly:

$$v_x^2 = v_{x0}^2 + 2a_x\,(x - x_0). \qquad \textbf{(2.22)}$$

Derivation 2.1

Mathematically, to obtain the time average of a quantity over a certain interval Δt, we have to integrate this quantity over the time interval and then divide by the time interval:

$$\begin{aligned} v_x &= \frac{1}{t}\int_0^t v_x(t')\,dt' = \frac{1}{t}\int_0^t (v_{x0} + a_x t')\,dt' \\ &= \frac{v_{x0}}{t}\int_0^t dt' + \frac{a_x}{t}\int_0^t t'\,dt' = v_{x0} + \tfrac{1}{2}a_x t \\ &= \tfrac{1}{2}v_{x0} + \tfrac{1}{2}(v_{x0} + a_x t) \\ &= \tfrac{1}{2}(v_{x0} + v_x). \end{aligned}$$

Page 46

This averaging procedure for the time interval t_0 to t is illustrated in Figure 2.14. You can see that the area of the trapezoid formed by the blue line representing $v(t)$ and the two vertical lines at t_0 and t is equal to the area of the square formed by the horizontal line to v_x and the two vertical lines. The base line for both areas is the horizontal t-axis. It is more apparent that these two areas are equal if you note that the yellow triangle (part of the square) and the orange triangle (part of the trapezoid) are equal in size. [Algebraically, the area of the square is $v_x(t - t_0)$, and the area of the trapezoid is $\frac{1}{2}(v_{x0} + v_x)(t - t_0)$. Setting these two areas equal to each other gives us equation 2.20 again.]

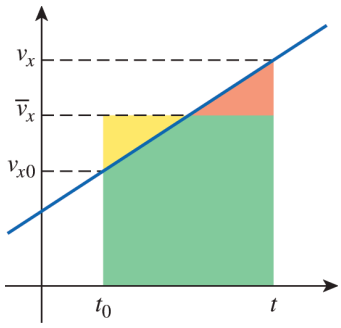

FIGURE 2.14 Graph of velocity versus time for motion with constant acceleration.

To derive the equation for the position, we take $t_0 = 0$, use the expression $v_x = v_{x0} + \frac{1}{2}a_x t$, and multiply both sides by the time:

$$\begin{aligned} v_x &= v_{x0} + \tfrac{1}{2}a_x t \\ \Rightarrow v_x t &= v_{x0} t + \tfrac{1}{2}a_x t^2. \end{aligned}$$

Now we compare this result to the expression we already obtained for x (equation 2.19) and find:

$$x = x_0 + v_{x0} t + \tfrac{1}{2}a_x t^2 = x_0 + v_x t.$$

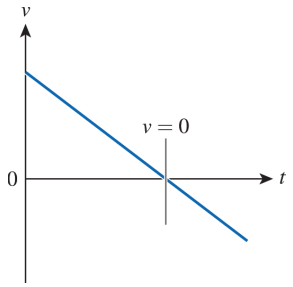
For the derivation of equation 2.22 for the square of the velocity, we solve $v_x = v_{x0} + a_x t$ for the time, getting $t = (v_x - v_{x0})/a_x$. We then substitute into the expression for the position, which is equation 2.19:

$$\begin{aligned} x &= x_0 + v_{x0} t + \tfrac{1}{2}a_x t^2 \\ &= x_0 + v_{x0}\left(\frac{v_x - v_{x0}}{a_x}\right) + \tfrac{1}{2}a_x\left(\frac{v_x - v_{x0}}{a_x}\right)^2 \\ &= x_0 + \frac{v_x v_{x0} - v^2{}_{x0}}{a_x} + \tfrac{1}{2}\frac{v^2{}_x + v^2{}_{x0} - 2v_x v_{x0}}{a_x}. \end{aligned}$$

Next, we subtract x_0 from both sides of the equation and then multiply by a_x:

$$a_x\,(x - x_0) = v_x v_{x0} - v_{x0}^2 + \tfrac{1}{2}\left(v_x^2 + v_{x0}^2 - 2v_x v_{x0}\right)$$
$$\Rightarrow a_x(x - x_0) = \tfrac{1}{2}v_x^2 - \tfrac{1}{2}v_{x0}^2$$
$$\Rightarrow v_x^2 = v_{x0}^2 + 2a_x\,(x - x_0).$$

Concept Check 2.7



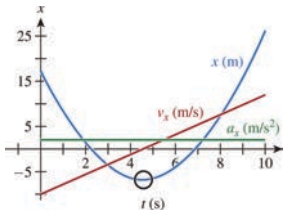
Consider the motion shown in the graph. At the instant that the velocity *v* is zero, what is the sign of the acceleration?

a) positive

b) negative

c) zero

Concept Check 2.8



The curve labeled *x*(m) describes the position of a car as a function of time. What is the car doing at t = 4.8 s marked by the circle?

a) The car is standing still at x = 0.

b) The car is standing still at x = −7 m.

c) The car is moving in the positive x-direction.

d) The car is moving in the negative x-direction.

e) The acceleration of the car is negative.

Here are the five kinematical equations we have obtained for the *special case of motion with constant acceleration* (where the initial time when $x = x_0$ and $v = v_0$ is taken to be 0):

$$\begin{aligned}
&\text{(i)} && x = x_0 + v_{x0}t + \tfrac{1}{2}a_x t^2 \\
&\text{(ii)} && x = x_0 + v_x t \\
&\text{(iii)} && v_x = v_{x0} + a_x t \\
&\text{(iv)} && v_x = \tfrac{1}{2}(v_x + v_{x0}) \\
&\text{(v)} && v_x^2 = v_{x0}^2 + 2a_x(x - x_0)
\end{aligned} \qquad \textbf{(2.23)}$$

These five equations allow us to solve many kinds of problems for motion in one dimension with constant acceleration. However, remember that if the acceleration is not constant, these equations will not give the correct solutions.

Many real-life problems involve motion along a straight line with constant acceleration. In these situations, equations 2.23 provide the template for answering any question about the motion. The following solved problem and example will illustrate how useful these kinematical equations are. However, keep in mind that physics is not simply about finding an appropriate equation and plugging in numbers, but is instead about understanding concepts. Only if you understand the underlying ideas will you be able to extrapolate from specific examples and become skilled at solving more general problems.

SOLVED PROBLEM 2.2 Airplane Takeoff

As an airplane rolls down a runway to reach takeoff speed, it is accelerated by its jet engines. On one particular flight, one of the authors of this book measured the acceleration produced by the plane's jet engines. Figure 2.15 shows the measurements.

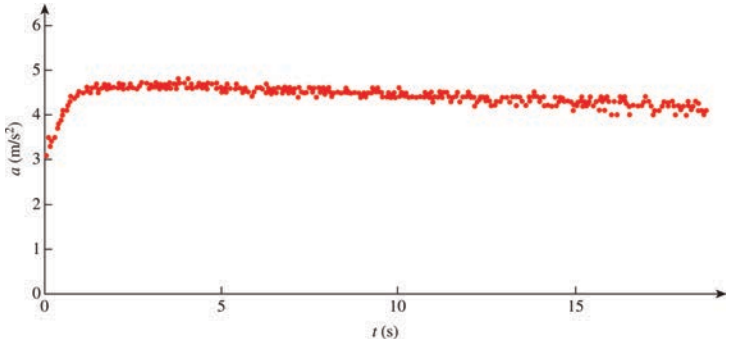


FIGURE 2.15 Data for the acceleration of a jet plane before takeoff.

You can see that the assumption of constant acceleration is not quite correct in this case. However, an average acceleration of $a_x = 4.3\ \text{m/s}^2$ over the 18.4 s (measured with a stopwatch) it took the airplane to take off is a good approximation.

PROBLEM

Assuming a constant acceleration of $a_x = 4.3\ \text{m/s}^2$ starting from rest, what is the airplane's takeoff velocity after 18.4 s? How far down the runway has the plane moved by the time it takes off?

SOLUTION

THINK

An airplane moving along a runway prior to takeoff is a nearly perfect example of one-dimensional accelerated motion. Because we are assuming constant acceleration, we know that the velocity increases linearly with time, and the displacement increases as the second power of time. Since the plane starts from rest, the initial value of the velocity is 0. As usual, we can

define the origin of our coordinate system at any location; it is convenient to locate it at the point of the plane's standing start.

SKETCH

The sketch in Figure 2.16 shows how we expect the velocity and displacement to increase for this case of constant acceleration, where the initial conditions are set at $v_{x0} = 0$ and $x_0 = 0$. Note that no scales have been placed on the axes, because displacement, velocity, and acceleration are measured in different units. Thus, the points at which the three curves intersect are completely arbitrary.

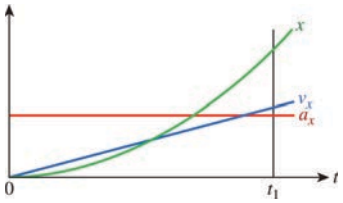

FIGURE 2.16 The acceleration, velocity, and displacement of the plane before takeoff.

RESEARCH

Finding the takeoff velocity is actually a straightforward application of equation 2.23(iii):

$$v_x = v_{x0} + a_x t.$$

Similarly, the distance down the runway that the airplane moves before taking off can be obtained from equation 2.23(i):

$$x = x_0 + v_{x0}t + \tfrac{1}{2}a_x t^2.$$

SIMPLIFY

The airplane accelerates from a standing start, so the initial velocity is $v_{x0} = 0$, and by our choice of coordinate system

origin, we have set $x_0 = 0$. Therefore, the equations for takeoff velocity and distance simplify to

$$\begin{aligned} v_x &= a_x t \\ x &= \tfrac{1}{2} a_x t^2. \end{aligned}$$

CALCULATE

The only thing left to do is to put in the numbers:

$$\begin{aligned} v_x &= \left(4.3\ \text{m/s}^2\right)(18.4\ \text{s}) = 79.12\ \text{m/s} \\ x &= \tfrac{1}{2}\left(4.3\ \text{m/s}^2\right)(18.4\ \text{s})^2 = 727.904\ \text{m}. \end{aligned}$$

ROUND

The acceleration was specified to two significant digits, and the time to three. Multiplying these two numbers must result in an answer that has two significant digits. Our final answers are therefore

$$\begin{aligned} v_x &= 79\ \text{m/s} \\ x &= 7.3 \cdot 10^2\ \text{m}. \end{aligned}$$

Note that the measured time to takeoff of 18.4 s was probably not actually that precise. If you have ever tried to determine the moment at which a plane starts to accelerate down the runway, you will have noticed that it is almost impossible to determine that point in time with an accuracy to 0.1 s.

DOUBLE-CHECK

As this book has repeatedly stressed, the most straightforward check of any answer to a physics problem is to make sure the units fit the situation. This is the case here, because we obtained displacement in units of meters and velocity in units

of meters per second. Solved problems in the rest of this book may sometimes skip this simple test; however, if you want to do a quick check for algebraic errors in your calculations, it can be valuable to first look at the units of the answer.

Now let's see if our answers have the appropriate orders of magnitude. A takeoff displacement of 730 m (~0.5 mi) is reasonable, because it is on the order of the length of an airport runway. A takeoff velocity of $v_x = 79$ m/s translates into

$$(79\ \text{m/s})(1\ \text{mi}/1609\ \text{m})(3600\ \text{s}/1\ \text{h}) \approx 180\ \text{mph}.$$

This answer also appears to be in the right ballpark.

ALTERNATIVE SOLUTION

Many problems in physics can be solved in several ways, because it is often possible to use more than one relationship between the known and unknown quantities. In this case, once we obtain the final velocity, we could use this information and solve kinematical equation 2.23(v) for x. This alternative approach results in

$$v_x^2 = v_{x0}^2 + 2a_x(x - x_0) \Rightarrow$$

$$x = x_0 + = 0 + = 7.3 \cdot 10^2\ \text{m}. \quad \frac{v_x^2 = v_{x0}^2}{2a_x} \quad \frac{(79\ \text{m/s})^2}{2(4.3\ \text{m/s}^2)}$$

Thus, we arrive at the same answer for the distance in a different way, giving us additional confidence that our solution makes sense.

Solved Problem 2.2 was a fairly easy one; solving it amounted to little more than plugging in numbers. Nevertheless, it shows that the kinematical equations we derived can be applied to real-world situations and lead to answers that have physical meaning. The following short example, this time from motor sports, addresses the same concepts of velocity and acceleration, but in a slightly different light.

EXAMPLE 2.4 Top Fuel Racing

Accelerating from rest, a top fuel race car (Figure 2.17) can reach 333.2 mph (= 148.9 m/s), a record established in 2003, at the end of a quarter mile (= 402.3 m). For this example, we will assume constant acceleration.

FIGURE 2.17 Top fuel NHRA race car.

Joshua Rainey Photography/Shutterstock

PROBLEM 1

What is the value of the race car's constant acceleration?

SOLUTION 1

Since the initial and final values of the velocity are given and the distance is known, we are looking for a relationship between these three quantities and the acceleration, the unknown.

In this case, it is most convenient to use kinematical equation 2.23(v) and solve for the acceleration, a_x:

$$v_x^2 = v_{x0}^2 + 2a_x(x - x_0) \Rightarrow a_x = \frac{v_x^2 - v_{x0}^2}{2(x - x_0)} = \frac{(148.9\ \text{m}}{2(402.3}$$

PROBLEM 2

How long does it take the race car to complete a quarter-mile run from a standing start?

SOLUTION 2

Because the final velocity is 148.9 m/s, the average velocity is [using equation 2.23(iv)]: $v_x = (148.9\ \text{m/s} + 0) = 74.45\ \text{m/s}$[1/2]. Relating this average velocity to the displacement and time using equation 2.23(ii), we obtain:

$$x = x_0 + v_x t \Rightarrow t = \frac{x - x_0}{v_x} = \frac{402.3\ \text{m}}{74.45\ \text{m/s}} = 5.40\ \text{s}.$$

Note that we could have obtained the same result by using kinematical equation 2.23(iii), because we already calculated the acceleration in Solution 1.

If you are a fan of top fuel racing, however, you know that the real record time for the quarter mile is slightly lower than 4.5 s. The reason our calculated answer is somewhat higher is that our assumption of constant acceleration is not quite correct. The acceleration of the car at the beginning of the race is actually higher than the value we calculated above, and the actual acceleration toward the end of the race is lower than our value.

From what you have seen up to now, it may appear that almost all problems involving constant acceleration can be solved by using equations 2.23. But it's important to remember that you can't apply these equations blindly. The following two solved problems illustrate this point.

SOLVED PROBLEM 2.3 Racing with a Head Start

Cheri has a new Dodge Charger with a Hemi engine and has challenged Vince, who owns a tuned VW GTI, to a race at a local track. Vince knows that Cheri's Charger is rated to go from 0 to 60 mph in 5.3 s, whereas his VW needs 7.0 s. Vince asks for a head start and Cheri agrees to give him exactly 1.0 s.

PROBLEM

How far down the track is Vince before Cheri gets to start the race? At what time does Cheri catch Vince? How far away from the start are they when this happens? (Assume constant acceleration for each car during the race.)

SOLUTION

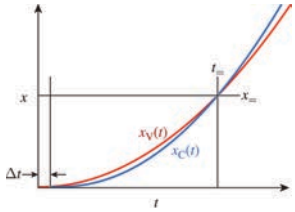
THINK

This race is a good example of one-dimensional motion with constant acceleration. The temptation is to look over the kinematical equations 2.23 and see which one we can apply. However, we have to be a bit more careful here, because the time delay between Vince's start and Cheri's start adds a complication. In fact, if you try to solve this problem using the kinematical equations directly, you will not get the right answer. Instead, this problem requires some careful definition of the time coordinates for each car.

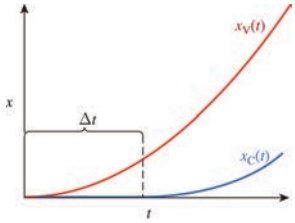
SKETCH

For our sketch, we plot time on the horizontal axis and position on the vertical axis. Both cars move with constant acceleration from a standing start, so we expect simple parabolas for their paths in this diagram.

Since Cheri's car has the greater acceleration, its parabola (blue curve in Figure 2.18) has the larger curvature and thus the steeper rise. Therefore, it is clear that Cheri will catch Vince at some point, but it is not yet clear where this point is.



(a)



(b)

FIGURE 2.18
Position versus time for the race between Cheri and Vince. Part (a) shows the entire duration of the race, and part (b) shows a magnified view of the start.

RESEARCH

We set up the problem quantitatively. We call the time delay before Cheri can start Δt, and we use the indices (subscripts) C for Cheri's Charger and V for Vince's VW. We put the coordinate system's origin at the starting line. Thus, both cars have initial position $x_C(t = 0) = x_V(t = 0) = 0$. Since both cars are at rest at the start, their initial velocities are zero. The equation of motion for Vince's VW is

$$x_V(t) = \tfrac{1}{2} a_V t^2.$$

Here we use the symbol a_{V} for the acceleration of the VW. We can calculate its value from the 0 to 60 mph time given by the problem statement, but we will postpone this step until it is time to put in the numbers.

To obtain the equation of motion for Cheri's Charger, we have to be careful, because she is forced to wait Δt after Vince has taken off. We can account for this delay with a shifted time: $t' = t - \Delta t$. Once t reaches the value of Δt, the time t' has the value 0 and then Cheri can take off. So her Charger's equation of motion is

$$x_{\mathrm{C}}(t) = \tfrac{1}{2} a_{\mathrm{C}} t'^2 = \tfrac{1}{2} a_{\mathrm{C}} (t - \Delta t)^2 \qquad \text{for } t \geq \Delta t.$$

Just like a_{v}, the constant acceleration a_{C} for Cheri's Charger will be evaluated below.

SIMPLIFY

When Cheri catches Vince, their coordinates will have the same value. We will call the time at which this happens $t_{=}$, and the coordinate where it happens $x_{=} \equiv x(t_{=})$. Because the two coordinates are the same, we have

$$x_{=} = \tfrac{1}{2} a_{\mathrm{v}} t^2_{=} = \tfrac{1}{2} a_{\mathrm{C}} (t_{=} - \Delta t)^2.$$

We can solve this equation for $t_{=}$ by dividing out the common factor of $\frac{1}{2}$ and then taking the square root of both sides of the equation:

$$\sqrt{a_{\mathrm{v}} t_{=}} = \sqrt{a_{\mathrm{C}}}(t_{=} - \Delta t) \Rightarrow t_{=}\left(\sqrt{a_{\mathrm{C}}} - \sqrt{a_{\mathrm{V}}}\right) = \Delta t \sqrt{a_{\mathrm{C}}}$$

Why do we use the positive root and discard the negative root here? The negative root would lead to a physically impossible solution: We are interested in the time when the two cars meet *after* they have left the start, not in a negative value that would imply a time before they left.

CALCULATE

Now we can get a numerical answer for each of the questions that were asked. First, let's figure out the values of the cars' constant accelerations from the 0 to 60 mph specifications given. We use $a = (v_x - v_{x0})/t$ and get

$$a_V = \frac{60 \text{ mph}}{7.0 \text{ s}} = \frac{26.8167 \text{ m/s}}{7.0 \text{ s}} = 3.83095 \text{ m/s}^2$$
$$a_C = \frac{60 \text{ mph}}{5.3 \text{ s}} = \frac{26.8167 \text{ m/s}}{5.3 \text{ s}} = 5.05975 \text{ m/s}^2.$$

Again, we postpone rounding our results until we have completed all steps in our calculations. However, with the values for the accelerations, we can immediately calculate how far Vince travels during the time $\Delta t = 1.0$ s:

$$x_V(1.0 \text{ s}) = \tfrac{1}{2}\left(3.83095 \text{ m/s}^2\right)(1.0 \text{ s})^2 = 1.91548 \text{ m}.$$

Now we can calculate the time when Cheri catches up to Vince:

$$t_= = \frac{\Delta t\sqrt{a_C}}{\sqrt{a_C} - \sqrt{a_V}} = \frac{(1.0 \text{ s})\sqrt{5.05975 \text{ m/s}^2}}{\sqrt{5.05975 \text{ m/s}^2} - \sqrt{3.83095 \text{ m/}}$$

At this time, both cars have traveled to the same point. Thus, we can insert this value into either equation of motion to find this position:

$$x_= = \tfrac{1}{2}a_V t^2{}_= = \tfrac{1}{2}\left(3.83095 \text{ m/s}^2\right)(7.70055 \text{ s})^2 = 113.5$$

ROUND

The initial data were specified to a precision of only two significant digits. Rounding our results to the same precision, we finally arrive at our answers: Vince receives a head start of

1.9 m, and Cheri will catch him after 7.7 s. At that time, they will be $1.1 \cdot 10^2$ m into their race.

DOUBLE-CHECK

It may seem strange to you that Vince's car was able to move only 1.9 m, or approximately half the length of the car, during the first second. Have we done anything wrong in our calculation? The answer is no; from a standing start, cars move only a comparatively short distance during the first second of acceleration. The following solved problem contains visible proof for this statement.

Figure 2.19 shows a plot of the equations of motion for both cars, this time with the proper units.

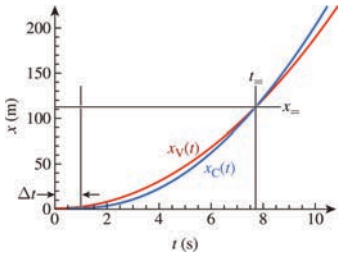


FIGURE 2.19 Plot of the parameters and equations of motion for the race between Cheri and Vince.

SOLVED PROBLEM 2.4 Accelerating Car

PROBLEM

You are given the image sequence shown in Figure 2.20, and you are told that there is a time interval of 0.333 s between successive frames. Can you determine how fast this car (whose length is 174.9 inches) was accelerating from rest? Also, can you give an estimate for the time it takes this car to go from 0 to 60 mph?

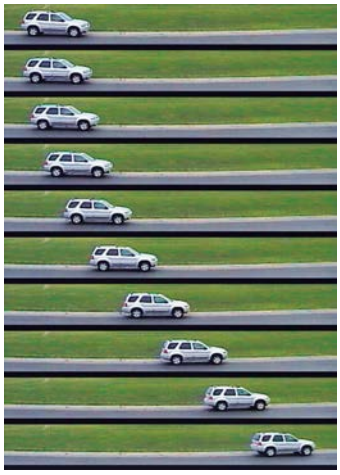

FIGURE 2.20
Video sequence of a car accelerating from a standing start.

W. Bauer and G. D. Westfall

SOLUTION

THINK

Acceleration is measured in dimensions of length per time per time. To find a number for the value of the acceleration, we need to know the time and length scales in Figure 2.20. The time scale is straightforward because we were given the information that 0.333 s passes between successive frames. We can get the length scale from the specified vehicle dimensions.

For example, if we focus on the length of the car and compare it to the overall width of the frame, we can find the distance the car covered between the first and the last frame (which are 3.000 s apart).

SKETCH

We draw vertical yellow lines over Figure 2.20, as shown in Figure 2.21. We put the center of the car at the line between the front and rear windows (the exact location is irrelevant, as long as we are consistent). Now we can use a ruler and measure the perpendicular distance between the two yellow lines, indicated by the yellow double-headed arrow in the figure. We can also measure the length of the car, indicated by the red double-headed arrow.

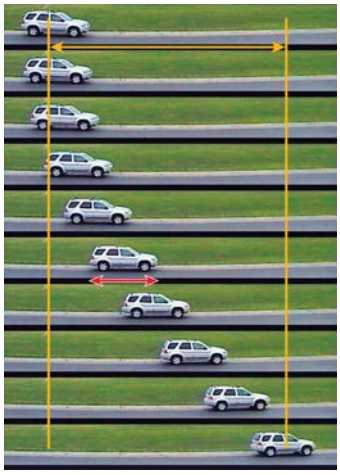

FIGURE 2.21
Determination of the length scale for Figure 2.20.

W. Bauer and G. D. Westfall

RESEARCH

Dividing the measured length of the yellow double-headed arrow by that of the red one gives us a ratio of 3.474. Since the two vertical yellow lines mark the position of the center of the car at 0.000 s and 3.000 s, we know that the car covered a distance of 3.474 car lengths in this time interval. The car

length was given as 174.9 in = 4.442 m. Thus, the total distance covered is $d = 3.474 \cdot \ell_{car} = 3.474 \cdot 4.442 \text{ m} = 15.4315 \text{ m}$ (remember that we round to the proper number of significant digits at the end).

SIMPLIFY

We have two choices on how to proceed. The first one is more complicated: We could measure the position of the car in each frame and then use difference formulas like those in Example 2.3. The other and much faster way to proceed is to assume constant acceleration and then use the measurements of the car's positions in only the first and last frames. We'll use the second way, but in the end we'll need to double-check that our assumption of constant acceleration is justified.

For a constant acceleration from a standing start, we simply have

$$\begin{aligned} x &= x_0 + \tfrac{1}{2} a_x t^2 \Rightarrow \\ d &= x - x_0 = \tfrac{1}{2} a_x t^2 \Rightarrow \\ a_x &= \frac{2d}{t^2}. \end{aligned}$$

This is the acceleration we want to find. Once we have the acceleration, we can give an estimate for the time from 0 to 60 mph by using $v_x = v_{x0} + at \Rightarrow t = (v_x - v_{x0})/a_x$. A standing start means $v_{x0} = 0$, and so we have

$$t(0 - 60 \text{ mph}) = \frac{60 \text{ mph}}{a_x}.$$

CALCULATE

We insert the numbers to find the acceleration:

$$a_x = \frac{2d}{t^2} = \frac{2 \cdot (15.4315\ \text{m})}{(3.000\ \text{s})^2} = 3.42922\ \text{m/s}^2.$$

Then, for the time from 0 to 60 mph, we obtain

$$t\ (0 - 60\ \text{mph}) = \frac{60\ \text{mph}}{a_x} = \frac{(60\ \text{mph})(1609\ \text{m/mi})}{3.42922\ \text{m/s}}$$

ROUND

The length of the car sets our length scale, and it was given to four significant figures. The time was given to three significant figures. Are we entitled to quote our results to three significant digits? The answer is no, because we also performed measurements on Figure 2.21, which are probably accurate to only two digits at best. In addition, you can see field-of-vision and lens distortions in the image sequence: In the first few frames, you see a little bit of the front of the car, and in the last few frames, a little bit of the back. Taking all this into account, our results should be quoted to two significant figures. So our final answer for the acceleration is

$$a_x = 3.4\ \text{m/s}^2.$$

For the time from 0 to 60 mph, we give

$$t(06 - 0\ \text{mph}) = 7.8\ \text{s}.$$

DOUBLE-CHECK

The numbers we have found for the acceleration and the time from 0 to 60 mph are fairly typical for cars or small SUVs; see also Solved Problem 2.3. Thus, we have confidence that we are not off by orders of magnitude.

What we must also double-check, however, is the assumption of constant acceleration. For constant acceleration from a standing start, the points $x(t)$ should fall on a parabola

$x(t) = \frac{1}{2} a_x t^2$. Therefore, if we plot x on the horizontal axis and t on the vertical axis as in Figure 2.22, the points $t(x)$ should follow a square root dependence: $t(x) = \sqrt{2x/a_x}$. This functional dependence is shown by the red curve in Figure 2.22. We can see that the same point of the car is hit by the curve in every frame, giving us confidence that the assumption of constant acceleration is reasonable.

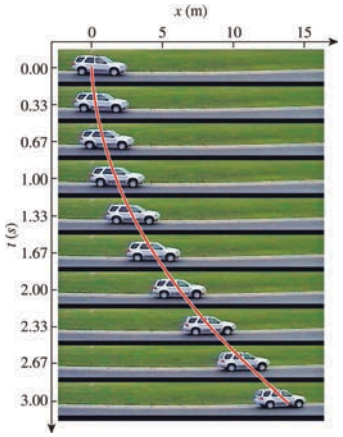

FIGURE 2.22
Graphical analysis of the accelerating car problem.

W. Bauer and G. D. Westfall

2.8 Free Fall

The acceleration due to the gravitational force is constant, to a good approximation, near the surface of Earth. If this statement is true, it must have observable consequences. Let's assume it is true and work out the consequences for the motion of objects under the influence of Earth's gravitational attraction. Then we'll compare our results with experimental observations and see if constant acceleration due to gravity makes sense.

The acceleration due to gravity near the surface of the Earth has the value $g = 9.81\ \mathrm{m/s^2}$. We call the vertical axis the y-axis and define the positive direction as up. Then the acceleration vector $\vec{a}$ has only a nonzero y-component, which is given by

$$a_y = -g. \tag{2.24}$$

This situation is a specific application of motion with constant acceleration, which we discussed earlier in this section. We modify equations 2.23 by substituting for acceleration from equation 2.24. We also use y instead of x to indicate that the displacement takes place in the y-direction. We obtain:

Page 53

$$\begin{aligned}
&\text{(i)} && y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2 \\
&\text{(ii)} && y = y_0 + v_y t \\
&\text{(iii)} && v_y = v_{y0} - gt \\
&\text{(iv)} && v_y = \tfrac{1}{2}(v_y + v_{y0}) \\
&\text{(v)} && v_y^2 = v_{y0}^2 - 2g(y - y_0)
\end{aligned} \tag{2.25}$$

Concept Check 2.9

Throwing a ball straight up into the air provides an example of free-fall motion. At the instant the ball reaches its maximum height, which of the following statements is true?

a) The ball's acceleration vector points down, and its velocity vector points up.

b) The ball's acceleration is zero, and its velocity vector points up.

c) The ball's acceleration vector points up, and its velocity vector points up.

d) The ball's acceleration vector points down, and its velocity is zero.

e) The ball's acceleration vector points up, and its velocity is zero.

f) The ball's acceleration is zero, and its velocity vector points down.

Concept Check 2.10

A ball is thrown upward with a speed v_1, as shown in Figure 2.24. The ball reaches a maximum height of $y = h$. What is the ratio of the speed of the ball, v_2, at $y = h/2$ in Figure 2.24b, to the initial upward speed of the ball, v_1, at $y = 0$ in Figure 2.24a?

a) $v_2/v_1 = 0$

b) $v_2/v_1 = 0.50$

c) $v_2/v_1 = 0.71$

d) $v_2/v_1 = 0.75$

e) $v_2/v_1 = 0.90$

Motion under the sole influence of a gravitational acceleration is called **free fall**, and equations 2.25 allow us to solve problems for objects in free fall.

Now let's consider an experiment that tested the assumption of constant gravitational acceleration. The authors went to the top of a building of height 12.7 m and dropped a computer from rest $(v_{y0} = 0)$ under controlled conditions. The computer's fall was recorded by a digital video camera. Because the camera records at 30 frames per second, we know the time information. Figure 2.23 displays 14 frames, equally spaced in time, from this experiment, with the time after release marked on the horizontal axis for each frame. The yellow curve superimposed on the frames has the form

$$y = 12.7 \text{ m} - \tfrac{1}{2}\left(9.81 \text{ m/s}^2\right)t^2,$$

which is what we expect for initial conditions $y_0 = 12.7$ m, $v_{y0} = 0$ and the assumption of a constant acceleration, $a_y = -9.81$ m/s^2. As you can see, the computer's fall follows this curve almost perfectly. This agreement is, of course, not a conclusive proof, but it is a strong indication that the gravitational acceleration is constant near the surface of Earth, and that it has the stated value.

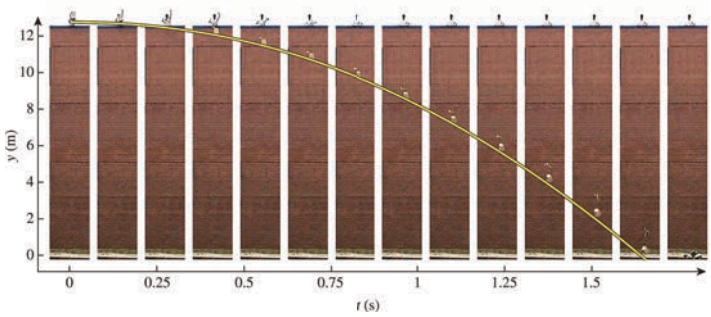

FIGURE 2.23 Free-fall experiment: dropping a computer off the top of a building.

W. Bauer and G. D. Westfall

In addition, the value of the gravitational acceleration is the same for all objects. This is by no means a trivial statement. Objects of different sizes and masses, if released from the same height, should hit the ground at the same time. Is this consistent with our everyday experience? Well, not quite! In a common lecture demonstration, a feather and a coin are dropped from the same height. It is easy to observe that the coin reaches the floor first, while the feather slowly floats down. This difference is due to air resistance. If this experiment is done in an evacuated glass tube, the coin and the feather fall at the same rate. We will return to air resistance in Chapter 4, but for now we can conclude that the gravitational acceleration near the surface of Earth is constant, has the absolute value of $g = 9.81\ \mathrm{m/s^2}$, and is the same for all objects provided we can neglect air resistance. In Chapter 4, we will examine the conditions under which the assumption of zero air resistance is justified.

To help you understand the answer to Concept Check 2.9, consider throwing a ball straight up, as illustrated in Figure 2.24. In Figure 2.24a, the ball is thrown upward with a velocity $\vec{v}$. When the ball is released, it experiences only the force of gravity and thus accelerates downward with the acceleration due to gravity, which is given by $\vec{a} = -g\hat{y}$. As the ball travels upward, the acceleration due

to gravity acts to slow the ball down. In Figure 2.24b, the ball is moving upward and has reached half of its maximum height, h. The ball has slowed down, but its acceleration is still the same. The ball reaches its maximum height in Figure 2.24c. Here the velocity of the ball is zero, but the acceleration is still $\vec{a} = -g\hat{y}$. The ball now begins to move downward, and the acceleration due to gravity acts to speed it up. In Figure 2.24d, the velocity of the ball is downward and the acceleration is still the same. Finally, the ball returns to $y = 0$ in Figure 2.24e. The velocity of the ball now has the same magnitude as when the ball was initially thrown upward, but its direction is now downward. The acceleration is still the same. Note that the acceleration remains constant and downward even though the velocity changes from upward to zero to downward.

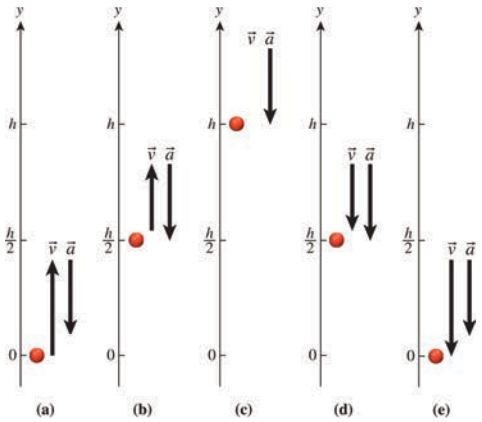

FIGURE 2.24 The velocity vector and acceleration vector of a ball thrown straight up in the air. (a) The ball is initially thrown upward at $y = 0$. (b) The ball going upward at a height of $y = h/2$. (c) The ball at its maximum height of $y = h$. (d) The ball coming down at $y = h/2$. (e) The ball back at $y = 0$ going downward.

EXAMPLE 2.5 Reaction Time

It takes time for a person to react to any external stimulus. For example, at the beginning of a 100-m dash in a track-and-field meet, a gun is fired by the starter. A slight time delay occurs before the runners come out of the starting blocks, due to their nonzero reaction time. In fact, it counts as a false start if a runner leaves the blocks less than 0.1 s after the gun is fired. Any shorter time indicates that the runner has "jumped the gun."

There is a simple test, shown in Figure 2.25, that you can perform to determine your reaction time. Your partner holds a meter stick, and you get ready to catch it when your partner releases it, as shown in the left frame of the figure. From the distance h that the meter stick falls after it is released until you grab it (shown in the right frame), you can determine your reaction time.

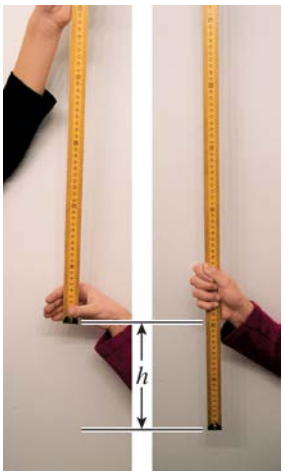

FIGURE 2.25 Simple experiment to measure reaction time.

W. Bauer and G. D. Westfall

PROBLEM

If the meter stick falls 0.20 m before you catch it, what is your reaction time?

SOLUTION

This situation is a free-fall scenario. For these problems, the solution invariably comes from one of equations 2.25. The problem we want to solve here involves the time as an unknown.

We are given the displacement, $h = y_0 - y$. We also know that the initial velocity of the meter stick is zero because it is released from rest. We can use kinematical equation 2.25(i): $y = y_0 + v_{y0}t - \frac{1}{2}gt^2$. With $h = y_0 - y$ and $v_0 = 0$, this equation becomes

$$\begin{aligned} y &= y_0 - \tfrac{1}{2}gt^2 \\ \Rightarrow h &= \tfrac{1}{2}gt^2 \\ \Rightarrow t &= \sqrt{\frac{2h}{g}} = \sqrt{\frac{2{\cdot}0.20\ \text{m}}{9.81\ \text{m/s}^2}} = 0.20\ \text{s}. \end{aligned}$$

Your reaction time was 0.20 s. This reaction time is typical. For comparison, when Usain Bolt established a world record of 9.69 s for the 100-m dash in August 2008, his reaction time was measured to be 0.165 s. (One year later Bolt ran the 100 m in 9.58 s, which is the current world record.)

Self-Test Opportunity 2.2

Sketch a graph of reaction time as a function of the distance the meter stick drops. Discuss whether this method is more precise for reaction times around 0.1 s or those around 0.3 s.

Let's consider one more free-fall scenario, this time with two moving objects.

Concept Check 2.11

If the reaction time of person B determined with the meter stick method is twice as long as that of person A, then the displacement h_B measured for person B in terms of the displacement h_A for person A is

a) $h_B = 2h_A$.

b) $h_B = \frac{1}{2}h_A$.

c) $h_B = \sqrt{2h_A}$.

d) $h_B = 4h_A$.

e) $h_B = \sqrt{\frac{1}{2}h_A}$.

SOLVED PROBLEM 2.5 Melon Drop

Suppose you decide to drop a melon from rest from the first observation platform of the Eiffel Tower. The initial height h from which the melon is released is 58.3 m above the head of your French friend Pierre, who is standing on the ground right below you. At the same instant you release the melon, Pierre shoots an arrow straight up with an initial velocity of 25.1 m/s. (Of course, Pierre makes sure the area around him is cleared and gets out of the way quickly after he shoots his arrow.)

PROBLEM

(a) How long after you drop the melon will the arrow hit it? (b) At what height above Pierre's head does this collision occur?

SOLUTION

THINK

At first sight, this problem looks complicated. We will solve it using the full set of steps and then examine a shortcut we could have taken. Obviously, the dropped melon is in free fall. However, because the arrow is shot straight up, the arrow is also in free fall, only with an upward initial velocity.

SKETCH

We set up our coordinate system with the y-axis pointing vertically up, as is conventional, and we locate the origin of the coordinate system at Pierre's head (Figure 2.26). Thus, the arrow is released from an initial position $y = 0$, and the melon from $y = h$.

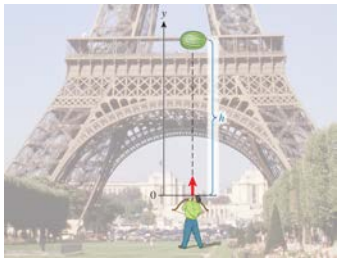

FIGURE 2.26 The melon drop (melon and person are not drawn to scale!).

Reed Kaestner/Corbis/Getty Images

RESEARCH

We use the subscripts m for "melon" and a for "arrow." We start with the general free-fall equation, $y = y_0 + v_{y0}t - \frac{1}{2}gt^2$, and use the initial conditions given for the melon $(v_{y0} = 0, y_0 = h = 58.3\ \text{m})$ and for the arrow $(v_{y0} \equiv v_{a0} = 25.1\ \text{m/s},\ y_0 = 0)$ to set up the two equations of free-fall motion:

$$y_\text{m}(t) = h - \tfrac{1}{2}gt^2$$
$$y_\text{a}(t) = v_{\text{a}0}t - \tfrac{1}{2}gt^2.$$

The key insight is that at t_c, the moment when the melon and arrow collide, their coordinates are identical:

$$y_\text{a}(t_\text{c}) = y_\text{m}(t_\text{c}).$$

SIMPLIFY

Inserting t_c into the two equations of motion and setting them equal results in

$$h - \tfrac{1}{2}gt_c^2 = v_{a0}t_c - \tfrac{1}{2}gt_c^2 \Rightarrow$$
$$h = v_{a0}t_c \Rightarrow$$
$$t_c = \tfrac{h}{v_{a0}}.$$

We can now insert this value for the time of collision in either of the two free-fall equations and obtain the height above Pierre's head at which the collision occurs. We select the equation for the melon:

$$y_m(t_c) = h - \tfrac{1}{2}gt_c^2.$$

CALCULATE

(a) All that is left to do is to insert the numbers given for the height of release of the melon and the initial velocity of the arrow, which results in

$$t_c = \frac{58.3\ \text{m}}{25.1\ \text{m/s}} = 2.32271\ \text{s}$$

for the time of impact.
(b) Using the number we obtained for the time, we find the position at which the collision occurs:

$$y_m(t_c) = 58.3\ \text{m} - \tfrac{1}{2}\left(9.81\ \text{m/s}^2\right)(2.32271\ \text{s})^2 = 31.837$$

ROUND

Since the initial values of the release height and the arrow velocity were given to three significant figures, we have to limit our final answers to three digits. Thus, the arrow will hit the melon after 2.32 s, and this will occur at a position 31.8 m above Pierre's head.

DOUBLE-CHECK

Could we have obtained the answers in an easier way? Yes, if we had realized that both melon and arrow fall under the influence of the same gravitational acceleration, and thus their free-fall motion does not influence the distance between them. This means that the time it takes them to meet is simply the initial distance between them divided by their initial velocity difference. With this realization, we could have written $t = h/v_{a0}$ right away and been done. However, thinking in terms of relative motion in this way takes some practice, and we will return to it in more detail in the next chapter.

Figure 2.27 shows the complete graph of the positions of arrow and melon as functions of time. The dashed portions of both graphs indicate where the arrow and melon would have gone, had they not collided.

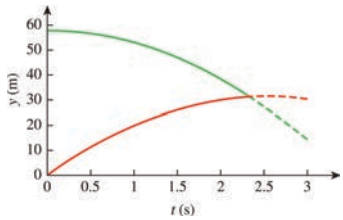

FIGURE 2.27 Position as a function of time for the arrow (red curve) and the melon (green curve).

ADDITIONAL QUESTION

What are the velocities of melon and arrow at the moment of the collision?

SOLUTION

We obtain the velocity by taking the time derivative of the position. For arrow and melon, we get

$$y_{\mathrm{m}}(t) = h - \tfrac{1}{2}gt^2 \Rightarrow v_{\mathrm{m}}(t) = \frac{dy_{\mathrm{m}}(t)}{dt} = -gt$$
$$y_{\mathrm{a}}(t) = v_{\mathrm{a}0}t - \tfrac{1}{2}gt^2 \Rightarrow v_{\mathrm{a}}(t) = \frac{dy_{a}(t)}{dt} = v_{\mathrm{a}0} - gt.$$

Now, inserting the time of the collision, 2.32 s, will produce the answers. Note that, unlike the positions of the arrow and the melon, the velocities of the two objects are not the same right before contact!

$$v_{\mathrm{m}}(t_{\mathrm{c}}) = -\left(9.81\ \mathrm{m/s^2}\right)(2.32\ \mathrm{s}) = -22.8\ \mathrm{m/s}$$
$$v_{\mathrm{a}}(t_{\mathrm{c}}) = (25.1\ \mathrm{m/s}) - \left(9.81\ \mathrm{m/s^2}\right)(2.32\ \mathrm{s}) = 2.34\ \mathrm{m/s}.$$

Furthermore, you should note that the difference between the two velocities is still 25.1 m/s, just as it was at the beginning of the trajectories.

We finish this problem by plotting (Figure 2.28) the velocities as a function of time. You can see that the arrow starts out with a velocity that is 25.1 m/s greater than that of the melon. As time progresses, arrow and melon experience the same change in velocity under the influence of gravity, meaning that their velocities maintain the initial difference.

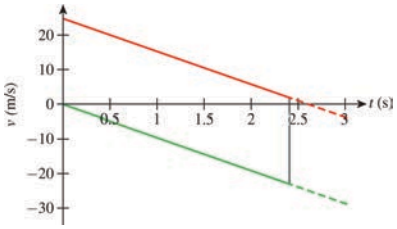

FIGURE 2.28
Velocities of the arrow (red curve) and melon (green curve) as a function of time.

Self-Test Opportunity 2.3

As you can see from the answer to Solved Problem 2.5, the velocity of the arrow is only 2.34 m/s when it hits the melon. This means that by the time the arrow hits the melon, its initial velocity has dropped substantially because of the effect of gravity. Suppose that the initial velocity of the arrow was smaller by 5.0 m/s. What would change? Would the arrow still hit the melon?

2.9 Reducing Motion in More Than One Dimension to One Dimension

Motion in one spatial dimension is not all there is to kinematics. We can also investigate more general cases, in which objects move in two or three spatial dimensions. We will do this in the next few chapters. However, in some cases, motion in more than one dimension can be reduced to one-dimensional motion. Let's consider a very interesting case of motion in two dimensions for which each segment can be described by motion in a straight line.

EXAMPLE 2.6 Aquathlon

The triathlon is a sporting competition that was invented by the San Diego Track Club in the 1970s and became an event in the Sydney Olympic Games in 2000. Typically, it consists of a 1.5-km swim, followed by a 40-km bike race, and finishing with a 10-km foot race. To be competitive, athletes must be able to swim the 1.5-km distance in less than 20 minutes, do the 40-km bike race in less than 70 minutes, and run the 10-km race in less than 35 minutes.

However, for this example, we'll consider a competition where thinking is rewarded in addition to athletic prowess. The competition consists of only two legs: a swim followed by a run. (This competition is sometimes called an *aquathlon*.) Athletes start a distance b = 1.5 km from shore, and the finish line is a distance a = 3 km along the shoreline, as shown in Figure 2.29. Suppose you can swim with a speed of $v_1 = 3.5$ km/h and can run across the sand with a speed of $v_2 = 14$ km/h.

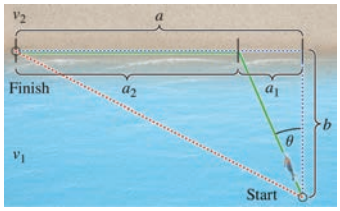

FIGURE 2.29 Geometry of the aquathlon course.

PROBLEM

What angle θ will result in the shortest finish time under these conditions?

SOLUTION

Clearly, the dotted red line marks the shortest distance between start and finish. This distance is $\sqrt{a^2 + b^2} = \sqrt{1.5^2 + 3^2}$ km $= 3.354$ km. Because this entire

path is in water, it couldn't be used for the aquathlon, but the time it would take to swim this distance is

$$t_{\text{red}} = \frac{\sqrt{a^2 + b^2}}{v^1} = \frac{3.354 \ \ \text{km}}{3.5 \ \ \text{km}/\text{h}} = 0.958 \ \text{h}.$$

Because you can run faster than you can swim, we can also try the approach indicated by the dotted blue line: swim straight to shore and then run. This takes

$$t_{\text{blue}} = \frac{b}{v_1} + \frac{a}{v_2} = \frac{1.5 \ \text{km}}{3.5 \ \text{km}/\text{h}} + \frac{3 \ \text{km}}{14 \ \text{km}/\text{h}} = 0.643 \ \text{h}.$$

Thus, the blue path is better than the red one. But is it the best? To answer this question, we need to search the angle interval from 0 (blue path) to $\tan^{-1}(3/1.5) = 63.43^\circ$ (red path). Let's consider the green path, with an arbitrary angle θ with respect to the straight line to shore (that is, the normal to the shoreline). On the green path, you have to swim a distance of $\sqrt{a_1^2 + b^2}$ and then run a distance of a_2, as indicated in Figure 2.29. The total time for this path is

$$t = \frac{\sqrt{a_1^2 + b^2}}{v_1} + \frac{a_2}{v_2}.$$

To find the minimum time, we can express the time in terms of the distance a_1 only, take the derivative of that time with respect to that distance, set that derivative equal to zero, and solve for the distance. Using a_1, we can then calculate the angle θ that the athlete must swim.

We can express the distance a_2 in terms of the given distance a and a_1:

$$a_2 = a - a_1.$$

We can then express the time to complete the race in terms of a_1:

$$t(a_1) = \frac{\sqrt{a_1^2 + b^2}}{v_1} + \frac{a - a_1}{v_2}. \qquad \textbf{(2.26)}$$

Taking the derivative with respect to a_1 and setting that result equal to zero gives us

$$\frac{dt(a_1)}{da_1} = \frac{a_1}{v_1\sqrt{a_1^2 + b^2}} - \frac{1}{v_2} = 0.$$

Solving for a_1 gives us

$$a_1 = \frac{bv_1}{\sqrt{v_2^2 - v_1^2}}.$$

In Figure 2.29, we can see that $\tan\theta = a_1/b$, so we can write

$$\tan\theta = \frac{a_1}{b} = \frac{\dfrac{bv_1}{\sqrt{v_2^2 - v_1^2}}}{b} = \frac{v_1}{\sqrt{v_2^2 - v_1^2}}.$$

We can simplify this result by looking at the triangle for the angle θ in Figure 2.30. The Pythagorean Theorem tells us that the hypotenuse of the triangle is

$$\sqrt{v_1^2 + v_2^2 - v_1^2} = v_2.$$

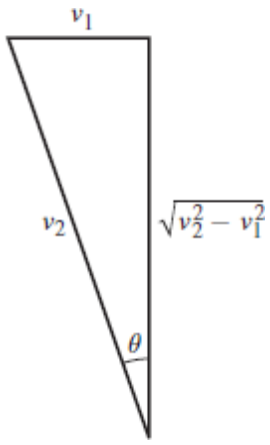

FIGURE 2.30
Relation between v_1, v_2, and θ.

We can then write

$$\sin\theta = \frac{v_1}{v_2}.$$

This result is very interesting because the distances a and b do not appear in it at all! Instead the sine of the optimum angle is simply the ratio of the speeds in water and on land. For the given values of the two speeds, this optimum angle is

$$\theta_{\mathrm{m}} = \sin^{-1}\frac{3.5}{14} = 14.48^{\circ}.$$

Inserting $a_1 = b\tan\theta_{\mathrm{m}}$ into equation 2.26, we find $t(\theta_m) = 0.629$ h. This time is approximately 49 seconds faster than swimming straight to shore and then running (blue path).

Strictly speaking, we have not quite shown that this angle results in the minimum time. To accomplish this, we also need to show that the second derivative of the time with respect to the angle is larger than zero. However, since we did find one extremum, and since its value is smaller than those of the boundaries, we know that this extremum is a true minimum.

Finally, Figure 2.31 plots the time, in hours, needed to complete the race for all angles between 0° and 63.43°, indicated by the green curve. This plot is obtained by

substituting $a_1 = b\tan\theta$ into equation 2.26 and using the identity $\tan^2\theta + 1 = \sec^2\theta$, which gives us

$$t(\theta) = \frac{\sqrt{(b\tan\theta)^2 + b^2}}{v_1} + \frac{a - b\tan\theta}{v_2} = \frac{b\sec\theta}{v_1} + \frac{a -}{}$$

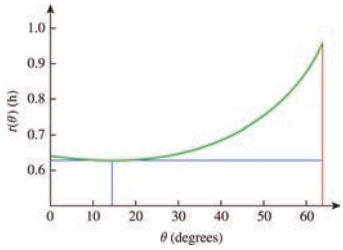

FIGURE 2.31
Duration of the race as a function of initial angle.

A vertical red line marks the maximum angle, corresponding to a straight-line swim from start to finish. The vertical blue line marks the optimum angle that we calculated, and the horizontal blue line marks the duration of the race for this angle.

Having completed Example 2.6, we can address a more complicated question: If the finish line is not at the shoreline, but at a perpendicular distance b away from the shoreline, as shown in Figure 2.32, what are the angles θ_1 and θ_2 that a competitor needs to select to achieve the minimum time?

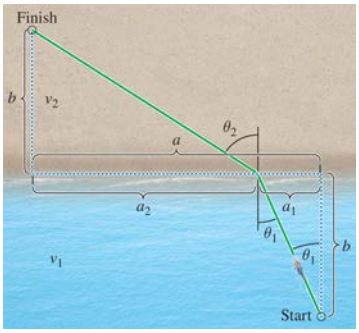

FIGURE 2.32 Modified aquathlon, with finish away from the shoreline.

We proceed in a fashion very similar to our approach in Example 2.6. However, now we have to realize that the time depends on two angles, θ_1 and θ_2. These two angles are not independent of each other. We can better see the relationship between θ_1 and θ_2 by changing the orientation of the lower triangle in Figure 2.32, as shown in Figure 2.33.

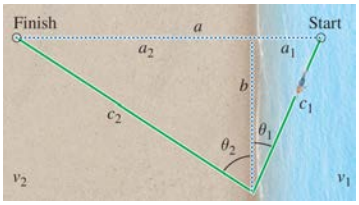

FIGURE 2.33 Same as previous figure, but with lower triangle reflected along the horizontal axis.

Now we see that the two right triangles a_1bc_1 and a_2bc_2 have a common side b, which helps us relate the two angles to each other. We can express the time to complete the race as

$$t = \frac{\sqrt{a_1^2 + b^2}}{v_1} + \frac{\sqrt{a_2^2 + b^2}}{v_2}.$$

Again realizing that $a_2 = a - a_1$, we can write

$$t(a_1) = \frac{\sqrt{a_1^2 + b^2}}{v_1} + \frac{\sqrt{(a - a_1)^2 + b^2}}{v_2}.$$

Taking the derivative of the time to complete the race with respect to a_1 and setting that result equal to zero, we obtain

$$\frac{dt(a_1)}{da_1} = \frac{a_1}{v_1\sqrt{a_1^2+b^2}} - \frac{a - a_1}{v_2\sqrt{(a - a_1)^2 + b^2}} = 0.$$

We can rearrange this equation to get

$$\frac{a_1}{v_1\sqrt{a_1^2+b^2}} = \frac{a - a_1}{v_2\sqrt{(a - a_1)^2 + b^2}} = \frac{a_2}{v_2\sqrt{a_2^2 + b^2}}$$

Looking at Figure 2.33 and referring to our previous result from Figure 2.30, we can see that

$$\sin\theta_1 = \frac{a_1}{\sqrt{a_1^2+b^2}} \qquad \text{and} \qquad \sin\theta_2 = \frac{a_2}{\sqrt{a_2^2+b^2}}.$$

We can insert these two results into the previous equation and finally find that to finish the race in the shortest time, a competitor should select angles that satisfy

$$\frac{\sin\theta_1}{v_1} = \frac{\sin\theta_2}{v_2}. \tag{2.27}$$

We can now see that our previous result, where we forced the running to take place along the beach, is a special case of this more general result, equation 2.27, with $\theta_2 = 90^\circ$.

Just as for that special case, we find that the relationship between the angles does not depend on the values of the displacements *a* and *b*, but depends only on the speeds with which

the competitor can move in the water and on land. The angles are still related to a and b by the overall constraint that the competitor has to get from the start to the finish. However, for the path of minimum time, the change in direction at the boundary between water and land, as expressed by the two angles θ_1 and θ_2, is determined exclusively by the ratio of the speeds v_1 and v_2.

The initial condition specified that the perpendicular distance b from the starting point to the shoreline be the same as the perpendicular distance between the shoreline and the finish. We did this to keep the algebra relatively brief. However, in the final formula you see that there are no more references to b; it has canceled out. Equation 2.27 is even valid in the case where the two perpendicular distances have different values. The ratio of angles for the path of minimum time is exclusively determined by the two speeds in the different media.

Interestingly, we will encounter the same relationship between two angles and two speeds when we study light and see that it changes direction at the interface between two media through which it moves at different speeds. In Chapter 32, we will discover that light also moves along the path of minimum time and that the result obtained in equation 2.27 is known as Snell's Law.

Finally, we make an observation that may appear trivial, but is not: If a competitor started at the point marked "Finish" in Figure 2.32 and ended up at the point marked "Start," he or she would have to take exactly the same path as the one we just calculated for the reverse direction. Snell's Law holds in both directions.

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- x is the x-component of the position vector. Displacement is the change in position: $\Delta x = x_2 - x_1$.
- Distance is the absolute value of displacement, $\ell = |\Delta x|$, and is a positive scalar for motion in one direction.
- The average velocity of an object in a given time interval is given by $\bar{v}_x = \dfrac{\Delta x}{\Delta t}$.
- The x-component of the (instantaneous) velocity *vector* is the derivative of the x-component of the position *vector* as a function of time, $v_x = \dfrac{dx}{dt}$.
- Speed is the absolute value of the velocity: $v = |v_x|$.
- The x-component of the (instantaneous) acceleration *vector* is the derivative of the x-component of the velocity *vector* as a function of time, $a_x = \dfrac{dv_x}{dt}$.
- For constant acceleration, five kinematical equations describe motion in one dimension:

  (i) $x = x_0 + v_{x0}t - \frac{1}{2}a_x t^2$

  (ii) $x = x_0 + \bar{v}_x t$

  (iii) $v_x = v_{x0} - a_x t$

  (iv) $\bar{v}_x = \frac{1}{2}(v_x + v_{x0})$

  (v) $v_x^2 = v_{x0}^2 + 2\mathrm{a_x(x - x_0)}$

  where x_0 is the initial position, v_{x0} is the initial velocity, and the initial time t_0 is set to zero.
- For situations involving free fall (constant acceleration), we replace the acceleration a with $-g$ and x with y in the above kinematical equations to obtain

  (i) $y = y_0 + v_{y0}t - \frac{1}{2}gt^2$

  (ii) $y = y_0 + \bar{v}_y t$

(iii) $v_y = v_{y0} - gt$

(iv) $\overline{v}_y = \frac{1}{2}(v_y + v_{y0})$

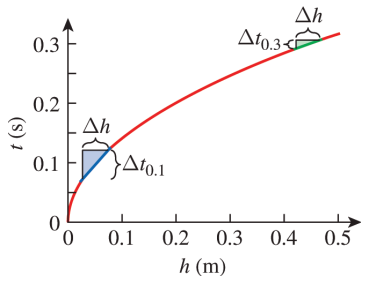
(v) $v_y^2 = v_{y0}^2 - 2g(\mathrm{y} - \mathrm{y}_0)$

where y_0 is the initial position, v_{y0} is the initial velocity, and the y-axis points up.

ANSWERS TO SELF-TEST OPPORTUNITIES

2.1 The result would not change, because a shift in the origin of the coordinate system has no influence on the net displacements or distances.

2.2



This method is more precise for longer reaction times, because the slope of the curve decreases as a function of the height, h. (In the graph, the slope at 0.1 s is indicated by the blue line, and that at 0.3 s by the green line.) So, a given uncertainty, Δh, in measuring the height results in a smaller uncertainty, Δt, in the value for the reaction time for longer reaction times.

2.3 The arrow would still hit the melon, but at the time of collision the arrow would already have negative velocity and thus be moving downward again. Thus, the melon would catch the arrow as it was falling. The collision would occur a bit later, after $t = 58.3\ \text{m}/(20.1\ \text{m/s}) = 2.90\ \text{s}$. The altitude of the collision would be quite a bit lower, at

$$y_{\text{m}}(t_{\text{c}}) = 58.3\ \text{m} - \tfrac{1}{2}\left(9.81\ \text{m/s}^2\right)(2.90\ \text{s})^2 = 17.0\ \text{m}$$

above Pierre's head.

PROBLEM-SOLVING GUIDELINES: ONE-DIMENSIONAL KINEMATICS

1. In one-dimensional motion, displacement and velocity are vectors and can have positive and negative values; distance and speed are always nonnegative scalar quantities. It is important to keep this distinction in mind.

2. For problems involving one-dimensional motion, first determine if the acceleration is constant or not. The five kinematical equations 2.23 *apply only to motion with constant acceleration.*

3. If the acceleration is constant, first check whether any of equations 2.23 can help. Although you shouldn't blindly apply these equations, there is no point to reinventing the wheel.

4. Free-fall problems simply involve special cases of motion with constant acceleration, where the value of the acceleration is $9.81\ \mathrm{m/s^2}$ in the downward direction.

MULTIPLE-CHOICE QUESTIONS

2.1 Two athletes jump straight up. Upon leaving the ground, Adam has half the initial speed of Bob. Compared to Adam, Bob jumps

a) 0.50 times as high.

b) 1.41 times as high.

c) twice as high.

d) three times as high.

e) four times as high.

2.2 Two athletes jump straight up. Upon leaving the ground, Adam has half the initial speed of Bob. Compared to Adam, Bob is in the air

a) 0.50 times as long.

b) 1.41 times as long.

c) twice as long.

d) three times as long.

e) four times as long.

2.3 A car is traveling due west at 20.0 m/s. Find the velocity of the car after 3.00 s if its acceleration is 1.0 m/s^2 due west. Assume that the acceleration remains constant.

a) 17.0 m/s west

b) 17.0 m/s east

c) 23.0 m/s west

d) 23.0 m/s east

e) 11.0 m/s south

2.4 A car is traveling due west at 20.0 m/s. Find the velocity of the car after 37.00 s if its acceleration is 1.0 m/s^2 due east. Assume

that the acceleration remains constant.

a) 17.0 m/s west

b) 17.0 m/s east

c) 23.0 m/s west

d) 23.0 m/s east

e) 11.0 m/s south

2.5 An electron, starting from rest and moving with a constant acceleration, travels 1.0 cm in 2.0 ms. What is the magnitude of this acceleration?

a) $25 \ \text{km}/\text{s}^2$

b) $20 \ \text{km}/\text{s}^2$

c) $15 \ \text{km}/\text{s}^2$

d) $10 \ \text{km}/\text{s}^2$

e) $5.0 \ \text{km}/\text{s}^2$

2.6 A car travels at 22.0 m/s north for 30.0 min and then reverses direction and travels at 28.0 m/s for 15.0 min. What is the car's total displacement?

a) $1.44 \cdot 10^4 \ \text{m}$

b) $6.48 \cdot 10^4 \ \text{m}$

c) $3.96 \cdot 10^4 \ \text{m}$

d) $9.98 \cdot 10^4 \ \text{m}$

2.7 Which of these statements is (are) true?

1. An object can have zero acceleration and be at rest.
2. An object can have nonzero acceleration and be at rest.
3. An object can have zero acceleration and be in motion.

a) 1 only

b) 1 and 3

c) 1 and 2

d) 1, 2, and 3

2.8 A car moving at 60 km/h comes to a stop in 4.0 s. What was its average deceleration?

a) $2.4\ \mathrm{m/s^2}$

b) $15\ \mathrm{m/s^2}$

c) $4.2\ \mathrm{m/s^2}$

d) $41\ \mathrm{m/s^2}$

2.9 You drop a rock from a cliff. If air resistance is neglected, which of the following statements is (are) true?

1. The speed of the rock will increase.
2. The speed of the rock will decrease.
3. The acceleration of the rock will increase.
4. The acceleration of the rock will decrease.

a) 1

b) 1 and 4

c) 2

d) 2 and 3

2.10 A car travels at 22.0 mph for 15.0 min and at 35.0 mph for 30.0 min. How far does it travel overall?

a) 23.0 m

b) $3.70 \cdot 10^4$ m

c) $1.38 \cdot 10^3$ m

d) $3.30 \cdot 10^2$ m

2.11 If the melon in Solved Problem 2.5 is thrown straight up with an initial velocity of 5.00 m/s at the same time that the arrow is shot upward, how long does it take before the collision occurs?

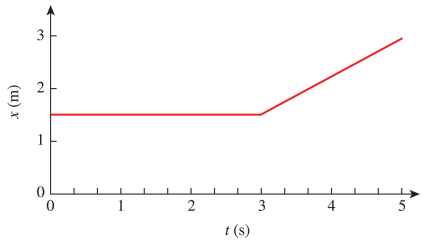
a) 2.32 s

b) 2.90 s

c) 1.94 s

d) They do not collide before the melon hits the ground.

2.12 The figure describes the position of an object as a function of time. Which one of the following statements is true?



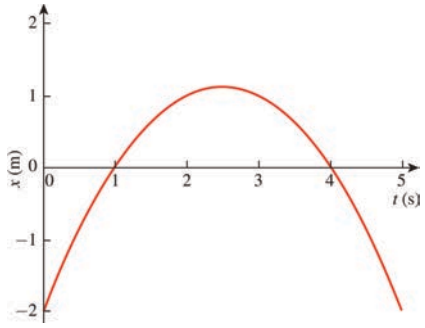
a) The position of the object is constant.

b) The velocity of the object is constant.

c) The object moves in the positive x-direction until $t = 3$ s, and then the object is at rest.

d) The object's position is constant until $t = 3$ s, and then the object begins to move in the positive x-direction.

e) The object moves in the positive x-direction from $t = 0$ to $t = 3$ s and then moves in the negative x-direction from $t = 3$ s to $t = 5$ s.



This figure describes the position of an object as a function of time. Refer to it to answer Questions 2.13–2.16.

2.13 Which one of the following statements is true at $t = 1$ s?

a) The x-component of the velocity of the object is zero.

b) The x-component of the acceleration of the object is zero.

c) The x-component of the velocity of the object is positive.

d) The x-component of the velocity of the object is negative.

2.14 Which one of the following statements is true at $t = 4$ s?

a) The x-component of the velocity of the object is zero.

b) The x-component of the acceleration of the object is zero.

c) The x-component of the velocity of the object is positive.

d) The x-component of the velocity of the object is negative.

2.15 Which one of the following statements is true at $t = 2.5$ s?

a) The x-component of the velocity of the object is zero.

b) The x-component of the acceleration of the object is zero.

c) The x-component of the velocity of the object is positive.

d) The x-component of the velocity of the object is negative.

2.16 Which one of the following statements is true at $t = 2.5$ s?

a) The x-component of the acceleration of the object is zero.

b) The x-component of the acceleration of the object is positive.

c) The x-component of the acceleration of the object is negative.

d) The acceleration of the object at that time can't be determined from the figure.

CONCEPTUAL QUESTIONS

2.17 Consider three ice skaters: Anna moves in the positive x-direction without reversing. Bertha moves in the negative x-direction without reversing. Christine moves in the positive x-direction and then reverses the direction of her motion. For which of these skaters is the magnitude of the average velocity smaller than the average speed over some time interval?

2.18 You toss a small ball vertically up in the air. How are the velocity and acceleration vectors of the ball oriented with respect to one another during the ball's flight up and down?

2.19 After you apply the brakes, the acceleration of your car is in the opposite direction to its velocity. If the acceleration of your car remains constant, describe the motion of your car.

2.20 Two cars are traveling at the same speed, and the drivers hit the brakes at the same time. The deceleration of one car is double that of the other. By what factor do the times required for the two cars to come to a stop differ?

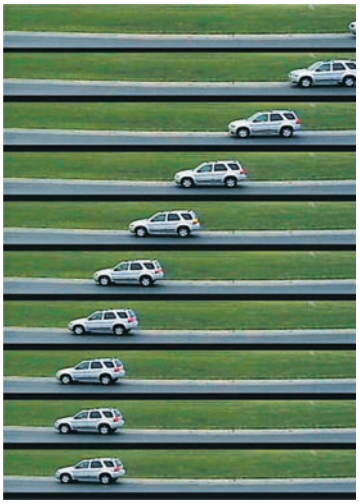
2.21 If the acceleration of an object is zero and its velocity is nonzero, what can you say about the motion of the object? Sketch graphs of velocity versus time and acceleration versus time to support your explanation.

2.22 Can an object's acceleration be in the opposite direction to its motion? Explain.

2.23 You and a friend are standing at the edge of a snow-covered cliff. At the same time, you both drop a snowball over the edge of the cliff. Your snowball is twice as heavy as your friend's. Neglect air resistance. (a) Which snowball will hit the ground first? (b) Which snowball will have the greater speed?

2.24 You and a friend are standing at the edge of a snow-covered cliff. At the same time, you throw a snowball straight upward with a speed of 8.0 m/s over the edge of the cliff and your friend throws

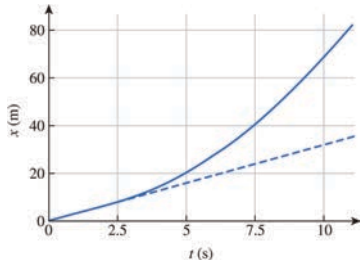
a snowball straight downward over the edge of the cliff with the same speed. Your snowball is twice as heavy as your friend's. Neglecting air resistance, which snowball will hit the ground first, and which will have the greater speed?



W. Bauer and G. D. Westfall

2.25 A car is slowing down and comes to a complete stop. The figure shows an image sequence of this process. The time between successive frames is 0.333 s, and the car is the same as the one in Solved Problem 2.4. Assuming constant acceleration, what is its value? Can you give some estimate of the error in your answer? How well justified is the assumption of constant acceleration?

2.26 A car moves along a road with a constant velocity. Starting at time t = 2.5 s, the driver accelerates with constant acceleration. The resulting position of the car as a function of time is shown by the blue curve in the figure.



a) What is the value of the constant velocity of the car before 2.5 s? (*Hint:* The dashed blue line is the path the car would take in the absence of the acceleration.)

b) What is the velocity of the car at $t = 7.5$ s? Use a graphical technique (i.e., draw a slope).

c) What is the value of the constant acceleration?

2.27 You drop a rock over the edge of a cliff from a height h. Your friend throws a rock over the edge from the same height with a speed v_0 vertically downward, at some time t after you drop your rock. Both rocks hit the ground at the same time. How long after you dropped your rock did your friend throw hers? Express your answer in terms of v_0, g, and h.

2.28 A wrench is thrown vertically upward with speed v_0. How long after its release is it halfway to its maximum height?

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One · and two ·· indicate increasing level of problem difficulty.

Section 2.2

2.29 A car travels north at 30.0 m/s for 10.0 min. It then travels south at 40.0 m/s for 20.0 min. What are the total distance the car travels and its displacement?

2.30 You ride your bike along a straight line from your house to a store 1000. m away. On your way back, you stop at a friend's house which is halfway between your house and the store.

a) What is your displacement?

b) What is the distance you have traveled?

c) After talking to your friend, you continue to your house. When you arrive back at your house, what is your displacement?

d) What is the total distance you have traveled?

Section 2.3

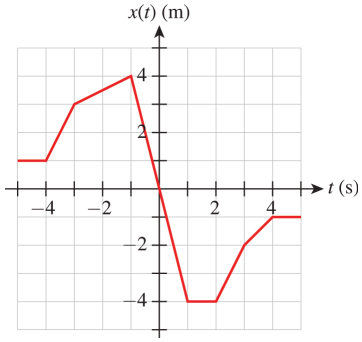
2.31 Running on a 50-m by 40-m rectangular track, you complete one lap in 100 s. What is your average velocity for the lap?

2.32 An electron moves in the positive x-direction a distance of 2.42 m in $2.91 \cdot 10^{-8}$ s, bounces off a moving proton, and then moves in the opposite direction a distance of 1.69 m in $3.43 \cdot 10^{-8}$ s.

a) What is the average velocity of the electron over the entire time interval?

b) What is the average speed of the electron over the entire time interval?

2.33 The graph describes the position of a particle in one dimension as a function of time.



a) In which time interval does the particle have its maximum speed? What is that speed?

b) What is the average velocity in the time interval between −5 s and +5 s?

c) What is the average speed in the time interval between −5 s and +5 s?

d) What is the ratio of the velocity in the interval between 2 s and 3 s to the velocity in the interval between 3 s and 4 s?

e) At what time(s) is the particle's velocity zero?

2.34 The position of a particle moving along the x-axis is given by $x = \left(11 + 14t - 2.0t^2\right)$, where t is in seconds and x is in meters.

What is the average velocity during the time interval from t = 1.0 s to t = 4.0 s?

·**2.35** The position of a particle moving along the x-axis is given by $x = 3.0t^2 - 2.0t^3$, where x is in meters and t is in seconds. What is the position of the particle when it achieves its maximum speed in the positive x-direction?

2.36 The rate of continental drift is on the order of 10.0 mm/yr. Approximately how long did it take North America and Europe to reach their current separation of about 3000 mi?

·**2.37** The position of an object as a function of time is given as $x = At^3 + Bt^2 + Ct + D$. The constants are $A = 2.10\ \text{m/s}^3$, $B = 1.00\ \text{m/s}^2$, $C = -4.10\ \text{m/s}$, and D = 3.00 m.

a) What is the velocity of the object at t = 10.0 s?

b) At what time(s) is the object at rest?

c) What is the acceleration of the object at t = 0.50 s?

d) Plot the acceleration as a function of time for the time interval from t = −10.0 s to t = 10.0 s.

·**2.38** The trajectory of an object is given by the equation

$$x(t) = (4.35\ \text{m}) + (25.9\ \text{m/s})t - \left(11.79\ \text{m/s}^2\right)t^2$$

a) For which time t is the displacement $x(t)$ at its maximum?

b) What is this maximum value?

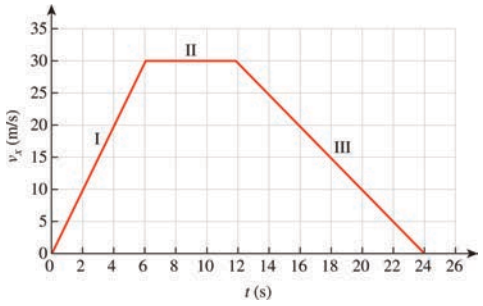
Section 2.4

2.39 A bank robber in a getaway car approaches an intersection at a speed of 45 mph. Just as he passes the intersection, he realizes that he needed to turn. So he steps on the brakes, comes to a complete stop, and then accelerates driving straight backward. He reaches a speed of 22.5 mph moving backward. Altogether his deceleration and re-acceleration in the opposite direction take 12.4 s. What is the average acceleration during this time?

2.40 A car is traveling west at 22.0 m/s. After 10.0 s, its velocity is 17.0 m/s in the same direction. Find the magnitude and direction of the car's average acceleration.

2.41 Your friend's car starts from rest and travels 0.500 km in 10.0 s. What is the magnitude of the constant acceleration required to do this?

2.42 A fellow student found in the performance data for his new car the velocity-versus-time graph shown in the figure.



a) Find the average acceleration of the car during each of the segments I, II, and III.

b) What is the total distance traveled by the car from t = 0 s to t = 24 s?

·**2.43** The velocity of a particle moving along the x-axis is given, for $t > 0$, by $v_x = \left(50.0\,t - 2.0\,t^3\right)$ m/s, where t is in seconds. What is the acceleration of the particle when (after t = 0) it achieves its maximum displacement in the positive x-direction?

·**2.44** The 2007 world record for the men's 100-m dash was 9.77 s. The third-place runner crossed the finish line in 10.07 s. When the winner crossed the finish line, how far was the third-place runner behind him?

a) Compute an answer that assumes that each runner ran at his average speed for the entire race.

b) Compute another answer that uses the result of Example 2.3, that a world-class sprinter runs at a speed of 12 m/s after an initial acceleration phase. If both runners in this race reach this speed, how far behind is the third-place runner when the winner finishes?

Section 2.5

2.45 On October 30, 2011, in an NFL football game between the Detroit Lions and the Denver Broncos, Lions left cornerback Chris Johnson intercepted a pass 1 yard behind the goal line, ran down the entire length of the football field on a straight line, and scored a touchdown. Video analysis of this scoring play showed the following approximate times for him to cross the yard lines painted on the field.

Yard	−1	0	5	10	15	20	25	30	35	40
Time	0.00	0.23	1.16	1.80	2.33	2.87	3.37	3.87	4.33	4.80

50	45	40	35	30	25	20	15	10	5	0
5.73	6.20	6.67	7.17	7.64	8.14	8.67	9.20	9.71	10.34	11.47

a) What was his average speed from the time he caught the ball until he reached midfield?

b) What was his average speed from the time he crossed midfield until he came to a stop 1 yard behind the opposite goal line?

c) What was the average acceleration during his entire run?

••2.46 An F-14 Tomcat fighter jet is taking off from the deck of the USS *Nimitz* aircraft carrier with the assistance of a steam-powered catapult. The jet's location along the flight deck is measured at intervals of 0.20 s. These measurements are tabulated as follows:

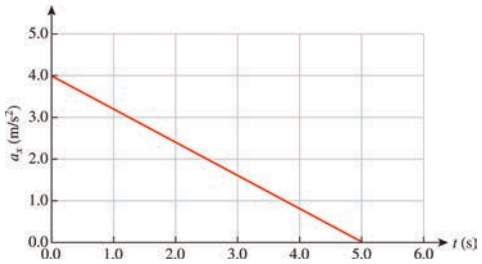
t (s)	0.00	0.20	0.40	0.60	0.80	1.00	1.20	1.40	1.60	1.80
x (m)	0.0	0.70	3.0	6.6	11.8	18.5	26.6	36.2	47.3	59.9

Use difference formulas to calculate the jet's average velocity and average acceleration for each time interval. After completing this analysis, can you say whether the F-14 Tomcat accelerated with approximately constant acceleration?

Section 2.6

2.47 A particle starts from rest at x = 0.00 and moves for 20.0 s with an acceleration of $+2.00\ \text{cm}/\text{s}^2$. For the next 40.0 s, the acceleration of the particle is $-4.00\ \text{cm}/\text{s}^2$. What is the position of the particle at the end of this motion?

2.48 A car moving in the x-direction has an acceleration a_x that varies with time as shown in the figure. At the moment t = 0.0 s, the car is located at x = 12 m and has a velocity of 6.0 m/s in the positive x-direction. What is the velocity of the car at t = 5.0 s?



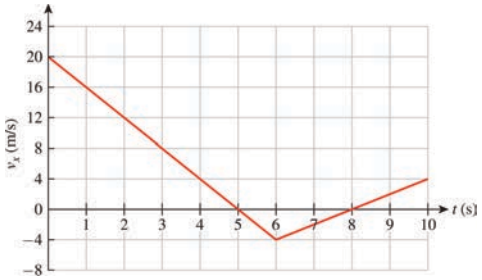
2.49 The velocity as a function of time for a car on an amusement park ride is given as $v = At^2 + Bt$ with constants $A = 2.0\ \text{m}/\text{s}^3$ and $B = 1.0\ \text{m}/\text{s}^2$. If the car starts at the origin, what is its position at t = 3.0 s?

2.50 An object starts from rest and has an acceleration given by $a = Bt^2 - \frac{1}{2}Ct$, where $B = 2.0\ \text{m}/\text{s}^4$ and $C = -4.0\ \text{m}/\text{s}^3$.

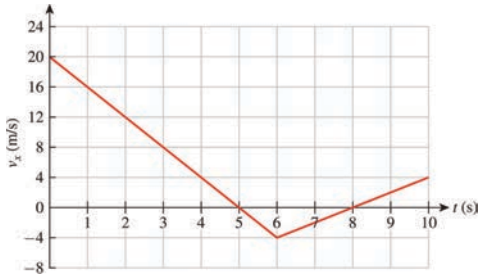
a) What is the object's velocity after 5.0 s?

b) How far has the object moved after t = 5.0 s?

·2.51 A car is moving along the x-axis and its velocity, v_x, varies with time as shown in the figure. If $x_0 = 2.0\ \text{m}$ at $t_0 = 2.0\ \text{s}$, what is the position of the car at t = 10.0 s?



·2.52 A car is moving along the x-axis and its velocity, v_x, varies with time as shown in the figure. What is the displacement, Δx of the car from t = 4 s to t = 9 s?



·2.53 A motorcycle starts from rest and accelerates as shown in the figure. Determine (a) the motorcycle's speed at t = 4.00 s and at t = 14.0 s and (b) the distance traveled in the first 14.0 s.

Section 2.7

2.54 How much time does it take for a car to accelerate from a standing start to 22.2 m/s if the acceleration is constant and the car covers 243 m during the acceleration?

2.55 A car slows down from a speed of 31.0 m/s to a speed of 12.0 m/s over a distance of 380. m.

a) How long does this take, assuming constant acceleration?

b) What is the value of this acceleration?

2.56 A runner of mass 57.5 kg starts from rest and accelerates with a constant acceleration of 1.25 m/s^2 until she reaches a velocity of 6.3 m/s. She then continues running with this constant velocity.

a) How far has she run after 59.7 s?

b) What is the velocity of the runner at this point?

2.57 A fighter jet lands on the deck of an aircraft carrier. It touches down with a speed of 70.4 m/s and comes to a complete stop over a distance of 197.4 m. If this process happens with constant deceleration, what is the speed of the jet 44.2 m before its final stopping location?

2.58 A bullet is fired through a board 10.0 cm thick, with a line of motion perpendicular to the face of the board. If the bullet enters with a speed of 400. m/s and emerges with a speed of 200. m/s, what is its acceleration as it passes through the board?

2.59 A car starts from rest and accelerates at 10.0 m/s^2. How far does it travel in 2.00 s?

2.60 An airplane starts from rest and accelerates at 12.1 m/s^2. What is its speed at the end of a 500.-m runway?

2.61 Starting from rest, a boat increases its speed to 5.00 m/s with constant acceleration.

a) What is the boat's average speed?

b) If it takes the boat 4.00 s to reach this speed, how far has it traveled?

·**2.62** Runner 1 is standing still on a straight running track. Runner 2 passes him, running with a constant speed of 5.1 m/s. Just as runner 2 passes, runner 1 accelerates with a constant acceleration of 0.89 $\mathrm{m/s^2}$. How far down the track does runner 1 catch up with runner 2?

·**2.63** A girl is riding her bicycle. When she gets to a corner, she stops to get a drink from her water bottle. At that time, a friend passes by her, traveling at a constant speed of 8.0 m/s.

a) After 20 s, the girl gets back on her bike and travels with a constant acceleration of 2.2 $\mathrm{m/s^2}$. How long does it take for her to catch up with her friend?

b) If the girl had been on her bike and rolling along at a speed of 1.2 m/s when her friend passed, what constant acceleration would she need to catch up with her friend in the same amount of time?

·**2.64** A speeding motorcyclist is traveling at a constant speed of 36.0 m/s when he passes a police car parked on the side of the road. The radar, positioned in the police car's rear window, measures the speed of the motorcycle. At the instant the motorcycle passes the police car, the police officer starts to chase the motorcyclist with a constant acceleration of 4.0 $\mathrm{m/s^2}$.

a) How long will it take the police officer to catch the motorcyclist?

b) What is the speed of the police car when it catches up to the motorcycle?

c) How far will the police car be from its original position?

·**2.65** Two train cars are on a straight, horizontal track. One car starts at rest and is put in motion with a constant acceleration of 2.00 $\mathrm{m/s^2}$. This car moves toward a second car that is 30.0 m away. The second car is moving away from the first car and is traveling at a constant speed of 4.00 m/s.

a) Where will the cars collide?

b) How long will it take for the cars to collide?

Section 2.8

2.66 A ball is tossed vertically upward with an initial speed of 26.4 m/s. How long does it take before the ball is back on the ground?

2.67 A stone is thrown upward, from ground level, with an initial velocity of 10.0 m/s.

a) What is the velocity of the stone after 0.50 s?

b) How high above ground level is the stone after 0.50 s?

2.68 A stone is thrown downward with an initial velocity of 10.0 m/s. The acceleration of the stone is constant and has the value of the free-fall acceleration, 9.81 $\mathrm{m/s^2}$. What is the velocity of the stone after 0.500 s?

2.69 A ball is thrown directly downward, with an initial speed of 10.0 m/s, from a height of 50.0 m. After what time interval does the ball strike the ground?

2.70 An object is thrown vertically upward and has a speed of 20.0 m/s when it reaches two thirds of its maximum height above the launch point. Determine its maximum height.

2.71 What is the velocity at the midway point of a ball able to reach a height y when thrown upward with an initial velocity v_0?

2.72 On August 2, 1971, astronaut David Scott, while standing on the surface of the Moon, dropped a 1.3-kg hammer and a 0.030-kg falcon feather from a height of 1.6 m. Both objects hit the Moon's surface 1.4 s after being released. What is the acceleration due to gravity on the surface of the Moon?

·**2.73** Bill Jones has a bad night in his bowling league. Feeling disgusted when he gets home, he drops his bowling ball out the window of his apartment, from a height of 63.17 m above the ground. John Smith sees the bowling ball pass by his window when it is 40.95 m above the ground. How much time passes from the time when John Smith sees the bowling ball pass his window to when it hits the ground?

·**2.74** Picture yourself in the castle of Helm's Deep from the *Lord of the Rings*. You are on top of the castle wall and are dropping rocks on assorted monsters that are 18.35 m below you. Just when

you release a rock, an archer located exactly below you shoots an arrow straight up toward you with an initial velocity of 47.4 m/s. The arrow hits the rock in midair. How long after you release the rock does this happen?

·**2.75** An object is thrown vertically and has an upward velocity of 25 m/s when it reaches one fourth of its maximum height above its launch point. What is the initial (launch) speed of the object?

·**2.76** In a fancy hotel, the back of the elevator is made of glass so that you can enjoy a lovely view on your ride. The elevator travels at an average speed of 1.75 m/s. A boy on the 15th floor, 80.0 m above the ground level, drops a rock at the same instant the elevator starts its ascent from the 1st to the 5th floor. Assume the elevator travels at its average speed for the entire trip and neglect the dimensions of the elevator.

a. How long after it was dropped do you see the rock?

b. How long does it take for the rock to reach ground level?

··2.77 You drop a water balloon straight down from your dormitory window 80.0 m above your friend's head. At 2.00 s after you drop the balloon, your friend (not aware that the balloon has water in it) fires a dart from a gun, which is at the same height as his head, directly upward toward the balloon with an initial velocity of 20.0 m/s.

a) How long after you drop the balloon will the dart burst the balloon?

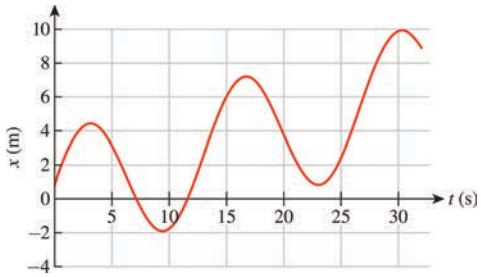
b) How long after the dart hits the balloon will your friend have to move out of the way of the falling water? Assume the balloon breaks instantaneously at the touch of the dart.

Additional Exercises

2.78 A runner of mass 56.1 kg starts from rest and accelerates with a constant acceleration of 1.23 m/s^2 until she reaches a velocity of 5.10 m/s. She then continues running at this constant velocity. How long does the runner take to travel 173 m?

2.79 A jet touches down on a runway with a speed of 142.4 mph. After 12.4 s, the jet comes to a complete stop. Assuming constant acceleration of the jet, how far down the runway from where it touched down does the jet stand?

2.80 On the graph of position as a function of time, mark the points where the velocity is zero and the points where the acceleration is zero.



2.81 A car accelerates from a standing start to 60.0 mph in 4.20 s. Assume that its acceleration is constant.

a) What is the acceleration?

b) How far does the car travel?

2.82 The minimum distance necessary for a car to brake to a stop from a speed of 100.0 km/h is 40.00 m on a dry pavement. What is the minimum distance necessary for this car to brake to a stop from a speed of 130.0 km/h on dry pavement?

2.83 A car moving at 60.0 km/h comes to a stop in t = 4.00 s. Assume uniform deceleration.

a) How far does the car travel while stopping?

b) What is its deceleration?

2.84 You are driving at 29.1 m/s when the truck ahead of you comes to a halt 200.0 m away from your bumper. Your brakes are in poor condition, and you decelerate at a constant rate of $2.4\ \text{m/s}^2$.

a) How close do you come to the bumper of the truck?

b) How long does it take you to come to a stop?

2.85 A train traveling at 40.0 m/s is headed straight toward another train, which is at rest on the same track. The moving train decelerates at $6.0\ \text{m/s}^2$, and the stationary train is 100.0 m away. How far from the stationary train will the moving train be when it comes to a stop?

2.86 The driver of a car traveling at 25.0 m/s applies the brakes, and the car decelerates uniformly at a rate of $1.2\ \text{m/s}^2$.

a) How far does it travel in 3.0 s?

b) What is its velocity at the end of this time interval?

c) How long does it take for the car to come to a stop?

d) What distance does the car travel before coming to a stop?

2.87 The fastest speed in NASCAR racing history was 212.809 mph (reached by Bill Elliott in 1987 at Talladega). If the race car decelerated from that speed at a rate of $8.0\ \text{m/s}^2$, how far would it travel before coming to a stop?

2.88 You are flying on a commercial airline on your way from Houston, Texas, to Oklahoma City, Oklahoma. Your pilot announces that the plane is directly over Austin, Texas, traveling at a constant speed of 245 mph, and will be flying directly over Dallas, Texas, 362 km away. How long will it be before you are directly over Dallas, Texas?

2.89 The position of a rocket sled on a straight track is given as $x = at^3 + bt^2 + c$, where $a = 2.0\ \text{m/s}^3, b = 2.0\ \text{m/s}^2,$ and $c = 3.0\ \text{m}$.

a) What is the sled's position between $t = 4.0\ \text{s}$ and $t = 9.0\ \text{s}$?

b) What is the average speed between $t = 4.0\ \text{s}$ and $t = 9.0\ \text{s}$?

2.90 A girl is standing at the edge of a cliff 100. m above the ground. She reaches out over the edge of the cliff and throws a rock straight upward with a speed 8.00 m/s.

a) How long does it take the rock to hit the ground?

b) What is the speed of the rock the instant before it hits the ground?

·**2.91** A double speed trap is set up on a freeway. One police cruiser is hidden behind a billboard, and another is some distance away under a bridge. As a sedan passes by the first cruiser, its speed is measured as 105.9 mph. Since the driver has a radar detector, he is alerted to the fact that his speed has been measured, and he tries to slow his car down gradually without stepping on the brakes and alerting the police that he knew he was going too fast. Just taking the foot off the gas leads to a constant deceleration. Exactly 7.05 s later, the sedan passes the second police cruiser. Now its speed is measured as only 67.1 mph, just below the local freeway speed limit.

a) What is the value of the deceleration?

b) How far apart are the two cruisers?

·**2.92** During a test run on an airport runway, a new race car reaches a speed of 258.4 mph from a standing start. The car accelerates with constant acceleration and reaches this speed mark at a distance of 612.5 m from where it started. What was its speed after one-fourth, one-half, and three-fourths of this distance?

·**2.93** The vertical position of a ball suspended by a rubber band is given by the equation

$$y(t) = (3.8\ \text{m})\sin(0.46\ t/\text{s} - 0.31) - (0.2\ \text{m/s})t + 5.0\ \text{m}$$

a) What are the equations for the velocity and acceleration of this ball?

b) For what times between 0 and 30 s is the acceleration zero?

·**2.94** The position of a particle moving along the *x*-axis varies with time according to the expression $x = 4t^2$, where *x* is in meters and *t* is in seconds.

a) Evaluate the particle's position at *t* = 2.00 s.

b) Evaluate its position at 2.00 s + Δt.

c) Evaluate the limit of $\Delta x/\Delta t$ as Δt approaches zero, to find the velocity at t = 2.00 s.

·**2.95** In 2005, Hurricane Rita hit several states in the southern United States. In the panic to escape its wrath, thousands of people tried to flee Houston, Texas, by car. One car full of college students traveling to Tyler, Texas, 199 miles north of Houston, moved at an average speed of 3.0 m/s for one-fourth of the time, then at 4.5 m/s for another one-fourth of the time, and at 6.0 m/s for the remainder of the trip.

a) How long did it take the students to reach their destination?

b) Sketch a graph of position versus time for the trip.

·**2.96** A ball is thrown straight upward in the air at a speed of 15.0 m/s. Ignore air resistance.

a) What is the maximum height the ball will reach?

b) What is the speed of the ball when it reaches 5.00 m?

c) How long will the ball take to reach 5.00 m above its initial position on the way up?

d) How long will the ball take to reach 5.00 m above its initial position on its way down?

·**2.97** The Bellagio Hotel in Las Vegas, Nevada, is well known for its Musical Fountains, which use 192 HyperShooters to fire water hundreds of feet into the air to the rhythm of music. One of the HyperShooters fires water straight upward to a height of 240. ft.

a) What is the initial speed of the water?

b) What is the speed of the water when it is at half this height on its way down?

c) How long will it take for the water to fall back to its original height from half its maximum height?

·**2.98** You are trying to improve your shooting skills by shooting at a can on top of a fence post. You miss the can, and the bullet, moving at 200. m/s, is embedded 1.5 cm into the post when it

comes to a stop. If constant acceleration is assumed, how long does it take for the bullet to stop?

·**2.99** You drive with a constant speed of 13.5 m/s for 30.0 s. You then steadily accelerate for 10.0 s to a speed of 22.0 m/s. You then slow smoothly to a stop in 10.0 s. How far have you traveled?

·**2.100** A ball is dropped from the roof of a building. It hits the ground and is caught at its original height 5.0 s later.

a) What was the speed of the ball just before it hit the ground?

b) How tall was the building?

c) You are watching from a window 2.5 m above the ground. The window opening is 1.2 m from the top to the bottom. At what time after the ball was dropped did you first see the ball in the window?

2.101 The position of a particle as a function of time is given as $x(t) = \frac{1}{4}x_0 e^{3\alpha t}$, where α is a positive constant.

a) At what time is the particle at $2x_0$?

b) What is the speed of the particle as a function of time?

c) What is the acceleration of the particle as a function of time?

d) What are the SI units for α?

2.102 The position of an object as a function of time is given by $x = At^4 - Bt^3 + C$.

a) What is the instantaneous velocity as a function of time?

b) What is the instantaneous acceleration as a function of time?

MULTI-VERSION EXERCISES

2.103 An object is thrown upward with a speed of 28.0 m/s. How long does it take it to reach its maximum height?

2.104 An object is thrown upward with a speed of 28.0 m/s. How high above the projection point is it after 1.00 s?

2.105 An object is thrown upward with a speed of 28.0 m/s. What maximum height above the projection point does it reach?

2.106 The acceleration due to gravity on the surface of Mars at the Equator is 3.699 m/s^2. How long does it take for a rock dropped from a height of 1.013 m to hit the surface?

2.107 The acceleration due to gravity on the surface of Mars at the Equator is 3.699 m/s^2. A rock released from rest takes 0.8198 s to reach the surface. From what height was the rock dropped?

2.108 A steel ball is dropped from a height of 12.37 m above the ground. What is its speed when it reaches 2.345 m above the ground?

2.109 A steel ball is dropped from a height of 13.51 m above the ground. How high above the ground is the ball when it has a speed of 14.787 m/s?

2.110 When a dropped steel ball reaches a height of 2.387 m above the ground, it has a speed of 15.524 m/s. From what height was the ball dropped?

Everyone has watched video footage of athletes competing in Olympic Games, during which they fly through the air. If you could freeze these

pictures during multiple points of the motion, as is done in Figure 3.1, you would see a symmetrical arch during the athlete's flight. This path is characteristic of a kind of two-dimensional motion known as *projectile motion*. You can see the same parabolic shape in water fountains, fireworks, basketball shots—any kind of isolated motion where the force of gravity is relatively constant and the moving object is dense enough that air resistance (a force that tends to slow down objects moving though air) can be ignored.

FIGURE 3.1 Multiple exposure sequence of a jump of Eileen Gu's gold medal winning run in the big air freestyle skiing competition at the 2022 Beijing Winter Olympics.

Jeremy White/The New York Times/Redux

This chapter extends Chapter 2's discussion of displacement, velocity, and acceleration to two-dimensional motion. The definitions of these vectors in two dimensions are very similar to the one-dimensional definitions, but we can apply them to a greater variety of real-life situations. Two-dimensional motion is still more restricted than general motion in three dimensions, but it applies to a wide range of common and important motions that we will consider throughout this course.

WHAT WE WILL LEARN

- We will learn to handle motion in two and three dimensions using methods developed for one-dimensional motion.
- We will determine the parabolic path of ideal projectile motion.
- We will calculate the maximum height and maximum range of an ideal projectile trajectory in terms of the initial velocity vector and the initial position.
- We will learn to describe the velocity vector of a projectile at any time during its flight.
- We will study qualitatively how realistic trajectories of objects like baseballs are affected by air friction and how such trajectories deviate from parabolic ones.
- We will learn to transform velocity vectors from one reference frame to another.

3.1 Three-Dimensional Coordinate Systems

Having studied motion in one dimension, we next tackle more complicated problems in two and three spatial dimensions. To describe this motion, we will work in Cartesian coordinates. In a three-dimensional Cartesian coordinate system, we choose the x- and y-axes to lie in the horizontal plane and the z-axis to point vertically upward (Figure 3.2). The three coordinate axes are at 90° (orthogonal) to one another, as required for a Cartesian coordinate system.

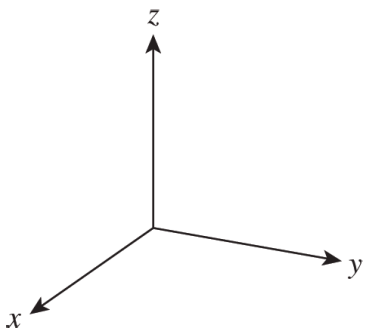

FIGURE 3.2 A right-handed *xyz* Cartesian coordinate system.

The convention followed without exception in this book is that the Cartesian coordinate system is **right-handed**. This convention means that you can obtain the relative orientation of the three coordinate axes using your right hand. To determine the positive directions of the three axes, hold your right hand with the thumb sticking straight up and the index finger pointing straight out; they will naturally have a 90° angle relative to each other. Then stick out your middle finger so that it is at a right angle with both the index finger and the thumb (Figure 3.3). The three axes are assigned to the fingers as shown in Figure 3.3: thumb is x, index finger is y, and middle finger is z. You can rotate your right hand in any direction, but the relative orientation of thumb and fingers stays the same. Your right hand can always be orientated in three-dimensional space in such a way that the axes assignments on your fingers can be brought into alignment with the schematic coordinate axes shown in Figure 3.2.

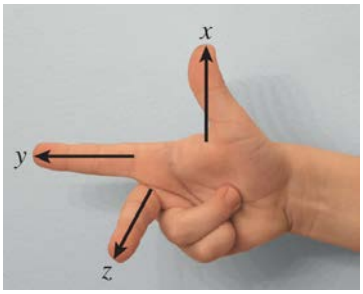

FIGURE 3.3 A right-handed Cartesian coordinate system.

W. Bauer and G. D. Westfall

With this set of Cartesian coordinates, a position vector can be written in component form as

$$\vec{r} = (x, y, z) = x\hat{x} + y\hat{y} + z\hat{z}. \tag{3.1}$$

A velocity vector is

$$\vec{v} = (v_x\ , v_y\ , v_y) = v_x\hat{x} + v_y\hat{y} + v_z\hat{z}. \tag{3.2}$$

For one-dimensional vectors, the time derivative of the position vector defines the velocity vector. This is also the case for more than one dimension:

$$\vec{v} = \frac{d\vec{r}}{dt} = \frac{d}{dt}\left(x\hat{x} + y\hat{y} + z\hat{z}\right) = \frac{dx}{dt}\hat{x} + \frac{dy}{dt}\hat{y} + \frac{dz}{dt}\hat{z}. \tag{3.3}$$

In the last step of this equation, we used the sum and product rules of differentiation, as well as the fact that the unit vectors are constant vectors (fixed directions along the coordinate axes and constant magnitude of 1). Comparing equations 3.2 and 3.3, we see that

$$v_x = \frac{dx}{dt}, \quad v_y = \frac{dy}{dt}, \quad v_z = \frac{dz}{dt}. \tag{3.4}$$

The same procedure leads us from the velocity vector to the acceleration vector by taking the time derivative of the former:

$$\overrightarrow{a} = \frac{\overrightarrow{dv}}{dt} = \frac{dv_x}{dt}\widehat{x} + \frac{dv_y}{dt}\hat{y} + \frac{dv_z}{dt}\hat{z} \tag{3.5}$$

.

We can therefore write the Cartesian components of the acceleration vector:

$$a_x = \frac{dv_x}{dt}, \quad a_y = \frac{dv_y}{dt}, \quad a_z = \frac{dv_z}{dt}. \tag{3.6}$$

3.2 Velocity and Acceleration in Two or Three Dimensions

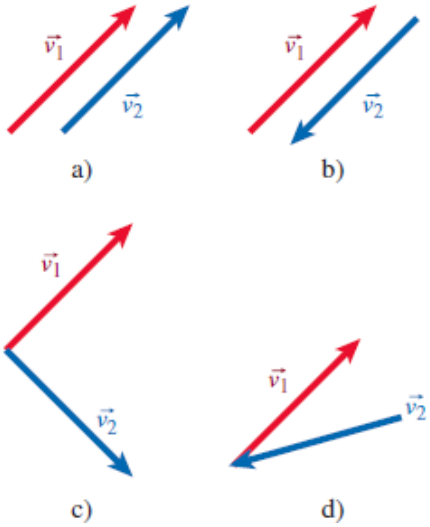
The most striking difference between velocity along a line and velocity in two or more dimensions is that the latter can change direction even in cases where the speed stays constant. Because acceleration is defined as a change in velocity—any change in velocity—divided by a time interval, there can be acceleration even when the magnitude of the velocity does not change.

Consider, for example, a particle moving in two dimensions (that is, in a plane). At time t_1, the particle has velocity $\vec{v}_1$ and at a later time t_2, the particle has velocity $\vec{v}_2$. The change in velocity of the particle is $\Delta\vec{v} = \vec{v}_2 - \vec{v}_1$. The average acceleration, $\vec{a}_{\text{ave}}$, for the time interval $\Delta t = t_2 - t_1$ is given by

$$\vec{a}_{\text{ave}} = \frac{\Delta\vec{v}}{\Delta t} = \frac{\vec{v}_2 - \vec{v}_1}{t_2 - t_1}. \tag{3.7}$$

Concept Check 3.1

In all of the cases shown below, the velocity vectors $\overrightarrow{v_1}$ and $\overrightarrow{v_2}$ have the same length. In which case does $\Delta\overrightarrow{v} = \overrightarrow{v_2} - \overrightarrow{v_1}$ have the *largest* absolute value?



e) All of the cases are identical.

Figure 3.4 shows three different cases for the change in velocity of a particle moving in two dimensions over a given time interval. Figure 3.4a shows the initial and final velocities of the particle having the same direction, but the magnitude of the final velocity is greater than the magnitude of the initial velocity. The resulting change in velocity and the average acceleration are in the same direction as the velocities. Figure 3.4b again shows the initial and final velocities pointing in the same direction, but the magnitude of the final velocity is less than the magnitude of the initial velocity. The resulting change in velocity and the average acceleration are in the opposite direction from the velocities. Figure 3.4c illustrates the case when the initial and final velocities have the same magnitude but the direction of the final velocity vector is different from the direction of the initial velocity vector. Even though the magnitudes of the initial and final velocity vectors are the same, the change in velocity and the average acceleration are not zero and can be in a direction not obviously related to the initial or final velocity directions.

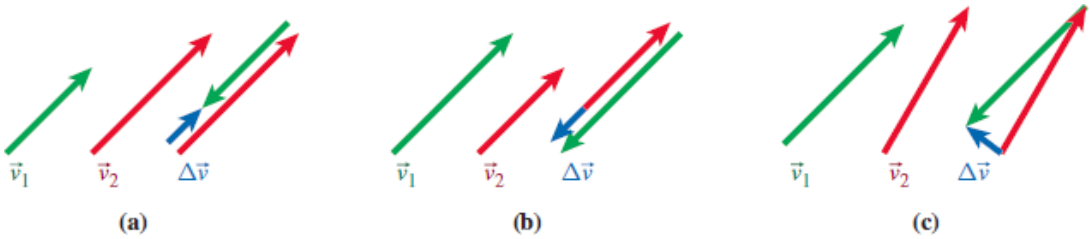


FIGURE 3.4 At time t_1, a particle has a velocity $\overrightarrow{v_1}$. At a later time t_2, the particle has a velocity $\overrightarrow{v_2}$. The average acceleration is given by $\overrightarrow{a}_{\text{ave}} = \Delta\overrightarrow{v}/\Delta t = \left(\overrightarrow{v_2} - \overrightarrow{v_1}\right)/(t_2 - t_1)$. (a) A time interval corresponding to $\left|\overrightarrow{v_2}\right| > \left|\overrightarrow{v_1}\right|$ with $\overrightarrow{v_2}$ and $\overrightarrow{v_1}$ in the same direction. (b) A time interval corresponding to $\left|\overrightarrow{v_2}\right| < \left|\overrightarrow{v_1}\right|$ with $\overrightarrow{v_2}$ and $\overrightarrow{v_1}$ in the same direction. (c) A time interval with $\left|\overrightarrow{v_2}\right| = \left|\overrightarrow{v_1}\right|$ but with $\overrightarrow{v_2}$ in a different direction from $\overrightarrow{v_1}$.

In general, an acceleration vector arises if an object's velocity vector changes in magnitude or direction. Any time an object travels along a curved path, in two or three dimensions, it must have acceleration. We will examine the components of acceleration in more detail in Chapter 9, when we discuss circular motion.

Concept Check 3.2

In all of the cases shown in Concept Check 3.1, the velocity vectors $\overrightarrow{v_1}$ and $\overrightarrow{v_2}$ have the same length. In which case does the acceleration $\overrightarrow{a} = \Delta\overrightarrow{v}/t$ have the *smallest* absolute value?

3.3 Ideal Projectile Motion

In some special cases of three-dimensional motion, the horizontal projection of the trajectory, or flight path, is a straight line. This situation occurs whenever the accelerations in the horizontal xy-plane are zero, so the object has constant velocity components, v_x and v_y, in the horizontal plane. Such a case is shown in Figure 3.5 for a baseball tossed in the air. In this case, we can assign new coordinate axes such that the x-axis points along the horizontal projection of the trajectory and the y-axis is the vertical axis. In this special case, the motion in three dimensions can in effect be described as a motion in two dimensions. A large class of real-life problems falls into this category, especially problems that involve ideal projectile motion.

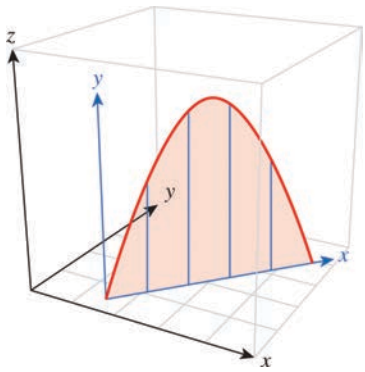

FIGURE 3.5
Trajectory in three dimensions reduced to a trajectory in two dimensions.

An **ideal projectile** is any object that is released with some initial velocity and then moves only under the influence of gravitational acceleration, which is assumed to be constant and in the vertical downward direction. A basketball free throw (Figure 3.6) is a good example of ideal projectile motion, as is the flight of a bullet or the trajectory of a car that becomes airborne. **Ideal projectile motion** neglects air resistance and wind speed, spin of the projectile, and other effects influencing the flight of real-life projectiles. For realistic situations

in which a golf ball, tennis ball, or baseball moves in air, the actual trajectory is not well described by ideal projectile motion and requires a more sophisticated analysis. We will discuss these effects in Section 3.5, but will not go into quantitative detail.

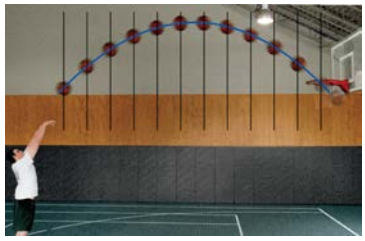

FIGURE 3.6
Photograph of a free throw with the parabolic trajectory of the basketball superimposed. This image was generated by superposition of 13 frames, with a time of 1/12 s between each two successive frames. Note that the ball moves the same horizontal distance (black vertical lines) between each two frames!

W. Bauer and G. D. Westfall

Let's begin with ideal projectile motion, with no effects due to air resistance or any other forces besides gravity. We work with two Cartesian components: x in the horizontal direction and y in the vertical (upward) direction. Therefore, the position vector for projectile motion is

$$\vec{r} = (x,\ y) = x\hat{x} + y\hat{y}, \tag{3.8}$$

and the velocity vector is

$$\overrightarrow{v} = (v_x, v_y) = v_x\widehat{x} + v_x\hat{y} = \left(\frac{dx}{dt}, \frac{dy}{dt}\right) = \frac{dx}{dt}\,\widehat{x} + \frac{dy}{dt}\,\hat{y}. \quad \textbf{(3.9)}$$

Given our choice of coordinate system, with a vertical y-axis, the acceleration due to gravity acts downward, in the negative y-direction; there is no acceleration in the horizontal direction:

$$\overrightarrow{a} = (0, -g) = -g\hat{y}. \quad \textbf{(3.10)}$$

For this special case of a constant acceleration only in the y-direction and with zero acceleration in the x-direction, we have a free-fall problem in the vertical direction and motion with constant velocity in the horizontal direction. The kinematical equations for the x-direction are those for an object moving with constant velocity:

$$x = x_0 + v_{x0}t \quad \textbf{(3.11)}$$

$$v_x = v_{x0}. \quad \textbf{(3.12)}$$

Just as in Chapter 2, we use the notation $v_{x0} \equiv v_x(t = 0)$ for the initial value of the x-component of the velocity. The kinematical equations for the y-direction are those for free-fall motion in one dimension:

$$y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2 \quad \textbf{(3.13)}$$

$$y = y_0 + \overline{v}_y t \quad \textbf{(3.14)}$$

$$v_y = v_{y0} - gt \tag{3.15}$$

$$\overline{v}_y = \tfrac{1}{2}(v_y + v_{y0}) \tag{3.16}$$

$$v^2{}_y = v^2{}_{y0} - 2g(y - y0) \tag{3.17}$$

.

For consistency, we write $v_{y0} \equiv v_y(t = 0)$ With these seven equations for the *x*- and *y*-components, we can solve any problem involving an ideal projectile. Notice that since two-dimensional motion can be split into separate one-dimensional motions, these equations are written in component form, without the use of unit vectors.

EXAMPLE 3.1 Shoot the Monkey

Many lecture demonstrations illustrate that motion in the x-direction and motion in the y-direction are indeed independent of each other, as assumed in the derivation of the equations for projectile motion. One popular demonstration, called "shoot the monkey," is shown in Figure 3.7. The demonstration is motivated by a story. A monkey has escaped from the zoo and has climbed a tree. The zookeeper wants to shoot the monkey with a tranquilizer dart in order to recapture it, but she knows that the monkey will let go of the branch it is holding onto at the sound of the gun firing. Her challenge is therefore to hit the monkey in the air as it is falling.

On the right, these frames have been combined into a single image with a superimposed yellow line indicating the initial aim of the projectile launcher.

W. Bauer and G. D. Westfall

PROBLEM

Where does the zookeeper need to aim to hit the falling monkey?

SOLUTION

The zookeeper must aim directly at the monkey, as shown in Figure 3.7, assuming that the time for the sound of the gun firing to reach the monkey is negligible and the speed of the dart is fast enough to cover the horizontal distance to the tree. As soon as the dart leaves the gun, it is in free fall, just like the monkey. Because both the monkey and the dart are in free fall, they fall with the same acceleration, independent of the dart's motion in the x-direction and of the dart's initial velocity. The dart and the monkey will meet at a point directly below the point from which the monkey dropped.

DISCUSSION

Any sharpshooter can tell you that, for a fixed target, you need to correct your gun sight for the free-fall motion of the projectile on the way to the target. As you can infer from Figure 3.7, even a bullet fired from a high-powered rifle will not fly in a straight line but will drop under the influence of gravitational acceleration. Only in a situation like the shoot-the-monkey demonstration, where the target is in free

fall as soon as the projectile leaves the muzzle, can one aim directly at the target without making corrections for the free-fall motion of the projectile.

Shape of a Projectile's Trajectory

Let's now examine the **trajectory** of a projectile in two dimensions. To find y as a function of x, we solve the equation $x = x_0 + v_{x0}t$ for the time, $t = (x - x_0)/v_{x0}$, and then substitute for t in the equation $y = y_0 + v_{y0}t - \frac{1}{2}gt^2$:

$$y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2 \Rightarrow$$
$$y = y_0 + v_{y0}\frac{x - x_0}{v_{x0}} - \tfrac{1}{2}g\left(\frac{x - x_0}{v_{x0}}\right)^2 \Rightarrow$$
$$y = \left(y_0 - \frac{v_{y0}x_0}{v_{x0}} - \frac{gx_0}{2v^2{}_{x0}}{}^2\right) + \left(\frac{v_{y0}}{v_{x0}} + \frac{gx_0}{v^2{}_{x0}}\right)x - \frac{g}{2v^2{}_{x0}}x^2.$$

Thus, the trajectory follows an equation of the general form $y = c + bx + ax^2$, with constants a, b, and c. This is the form of an equation for a parabola in the xy-plane. It is customary to set the x-component of the initial point of the parabola equal to zero: $x_0 = 0$. In this case, the equation for the parabola becomes

$$y = y_0 + \frac{v_{y0}}{v_{x0}}x - \frac{g}{2v^2{}_{x0}}x^2 \qquad \textbf{(3.19)}$$

The trajectory of the projectile is completely determined by three input constants. These constants are the initial height of the release of the projectile, y_0, and the x- and y-components of the initial velocity vector, v_{x0} and v_{y0}, as shown in Figure 3.8.

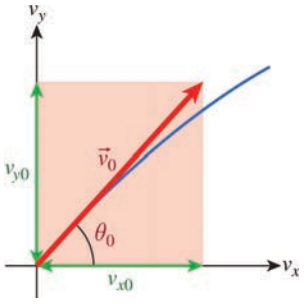

FIGURE 3.8 Initial velocity vector $\vec{v}_0$ and its components, v_{x0} and v_{y0}.

We can also express the initial velocity vector $\overrightarrow{v_0}$ in terms of its magnitude, v_0, and direction, θ_0. Expressing $\overrightarrow{v_0}$ in this manner involves the transformation

$$\begin{aligned} v_0 &= \sqrt{{v^2}_{x0} + {v^2}_{y0}} \\ \theta_0 &= \tan^{-1} \frac{v_{y0}}{v_{x0}}. \end{aligned} \tag{3.20}$$

In Chapter 1, we discussed this transformation from Cartesian coordinates to length and angle of the vector, as well as the inverse transformation:

$$\begin{aligned} v_{x0} &= v_0 \ \cos\theta_0 \\ v_{y0} &= v_0 \ \sin\theta_0. \end{aligned} \tag{3.21}$$

Expressed in terms of the magnitude and direction of the initial velocity vector, the equation for the path of the projectile becomes

$$y = y_0 + (\tan\theta_0)x - \frac{g}{2{v^2}_0 \cos^2\theta_0} x^2. \tag{3.22}$$

The fountain shown in Figure 3.9 is in the Detroit Metropolitan Wayne County (DTW) airport. You can clearly see that the water shot out of many pipes traces almost perfect parabolic trajectories.

FIGURE 3.9 A fountain with water following parabolic trajectories.

W. Bauer and G. D. Westfall

Note that because a parabola is symmetric, a projectile takes the same amount of time and travels the same distance from its launch point to the top of its trajectory as from the top of its trajectory back to launch level. Also, the speed of a projectile at a given height on its way up to the top of its trajectory is the same as its speed at that same height going back down.

Time Dependence of the Velocity Vector

From equation 3.12, we know that the *x*-component of the velocity is constant in time: $v_x = v_{x0}$. This result means that a projectile will cover the same horizontal distance in each time interval of the same duration. Thus, in a video of projectile motion, such as a basketball player shooting a free throw as in Figure 3.6, or the path of the dart in the shoot-the-monkey demonstration in Figure 3.7, the horizontal displacement of the projectile from one frame of the video to the next will be constant.

The *y*-component of the velocity vector changes according to equation 3.15, $v_y = v_{y0} - gt$; that is, the projectile falls with constant acceleration. Typically, projectile motion starts with a positive value, v_{y0}. The apex (highest point) of the trajectory is reached at the point where $v_y = 0$ and the projectile is moving only in the horizontal direction. At the apex, the *y*-component of the velocity is momentarily zero as it changes sign from positive to negative.

We can indicate the instantaneous values of the *x*- and *y*-components of the velocity vector on a plot of *y* versus *x* for the flight path of a projectile (Figure 3.10). The *x*-components, v_x, of the velocity vector are shown by green arrows, and the *y*-components, v_y, by red arrows. Note the identical lengths of the green arrows, demonstrating the fact that v_x remains constant. Each blue arrow is the vector sum of the *x*- and *y*-velocity components and depicts the instantaneous velocity vector along the path. Note that the direction of the velocity vector is always tangential to the trajectory. This is because the slope of the velocity vector is

$$\frac{v_y}{v_x} = \frac{dy/dt}{dx/dt} = \frac{dy}{dx},$$

which is also the local slope of the flight path. At the top of the trajectory, the green and blue arrows are identical because the velocity vector has only an *x*-component—that is, it points in the horizontal direction.

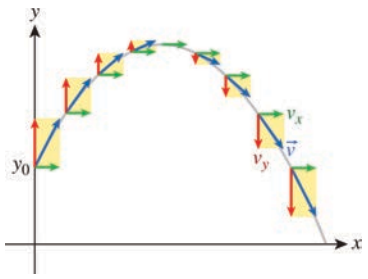

FIGURE 3.10 Graph of a parabolic trajectory with the velocity vector and its Cartesian components shown at constant time intervals.

Concept Check 3.3

At the top of the trajectory of any projectile, which of the following statement, if any, is (are) true?

a) The acceleration is zero.

b) The *x*-component of the acceleration is zero.

c) The *y*-component of the acceleration is zero.

d) The speed is zero.

e) The *x*-component of the velocity is zero.

f) The *y*-component of the velocity is zero.

Although the vertical component of the velocity vector is equal to zero at the top of the trajectory, the gravitational acceleration has the same constant value as on any other part of the trajectory. Beware of the common misconception that the gravitational acceleration is equal to zero at the top of the trajectory. The gravitational acceleration has the same constant value everywhere along the trajectory.

Finally, let's explore the functional dependence of the absolute value of the velocity vector on time and/or the y-coordinate. We start with the dependence of $|\vec{v}|$ on y. We use the fact that the absolute value of a vector is given as the square root of the sum of the squares of the components.

Then we use kinematical equation 3.12 for the x-component and kinematical equation 3.17 for the y-component. We obtain

$$\left|\vec{v}\right| = \sqrt{v_x^2 + v_y^2} = \sqrt{v_{x0}^2 + v_{y0}^2 - 2g(y - y_0)} = \sqrt{v_0^2 - 2g(y - y_0}$$

.

Note that the initial launch angle does not appear in this equation. The absolute value of the velocity—the speed—depends only on the initial value of the speed and the difference between the y-coordinate and the initial launch height. Thus, if we release a projectile from a certain height above ground and want to know the speed with which it hits the ground, it does not matter if the projectile is shot straight up, or horizontally, or straight down. Chapter 5 will discuss the concept of kinetic energy, and then the reason for this seemingly strange fact will become more apparent.

Self-Test Opportunity 3.1

What is the dependence of $\left|\vec{v}\right|$ on the x-coordinate?

3.4 Maximum Height and Range of a Projectile

When launching a projectile, for example, throwing a ball, we are often interested in the **range** (R), or how far the projectile will travel horizontally before returning to its original vertical position, and the **maximum height** (H) it will reach. These quantities R and H are illustrated in Figure 3.11. We find that the maximum height reached by the projectile is

$$H = y_0 + \frac{v_{y0}^2}{2g}. \tag{3.24}$$

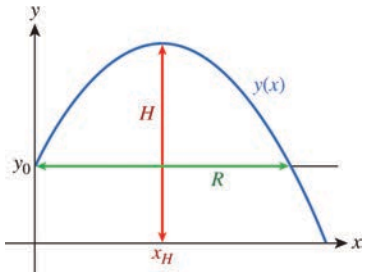

FIGURE 3.11 The maximum height (red) and range (green) of a projectile.

We'll derive this equation below. We'll also derive this equation for the range:

$$R = \frac{v_0^2}{g}\sin 2\theta_0 \tag{3.25}$$

,

where v_0 is the absolute value of the initial velocity vector and θ_0 is the launch angle. The maximum range, for a given fixed value of v_0, is reached when $\theta_0 = 45^\circ$.

DERIVATION 3.1

Let's investigate the maximum height of the projectile first. To determine its value, we obtain an expression for the height, differentiate it, set the result equal to zero, and solve for the maximum height. Suppose v_0 is the initial speed and θ_0 is the launch angle. We take the derivative of the path function $y(x)$, equation 3.22, with respect to x:

$$\frac{dy}{dx} = \frac{d}{dx}\left(y_0 + (\tan\theta_0)x - \frac{g}{2v_0^2\ \cos^2\theta_0}x^2\right) = \tan\theta_0 - \frac{}{v_0^2\ \mathrm{cc}}$$

Now we look for the point x_H where the derivative is zero:

$$0 = \tan\ \theta_0 - \frac{g}{v_0^2\ \cos^2\ \theta_0}x_H$$

$$\Rightarrow x_H = \frac{v_0^2\ \cos^2\ \theta_0\ \tan\ \theta_0}{g} = \frac{v_0^2}{g}\sin\ \theta_0\ \cos\ \theta_0 = \frac{v_0^2}{2g}\sin\ 2\theta$$

In the second line above, we used the trigonometric identities $\tan\theta = \sin\theta/\cos\theta$ and $2\sin\theta\ \cos\theta = \sin 2\theta$. Now we insert this value for x into equation 3.22 and obtain the maximum height, H:

$$H \equiv y(x_H) = y_0 + x_H\ \tan\theta_0 - \frac{g}{2v_0^2\ \cos^2\ \theta_0}x_H^2$$

$$= y_0 + \frac{v_0^2}{2g}\sin 2\theta_0\ \tan\theta_0 - \frac{g}{2v_0^2\ \cos^2\ \theta_0}\left(\frac{v_0^2}{2g}\sin 2\theta_0\right)^2$$

$$= y_0 + \frac{v_0^2}{g}\sin^2\theta_0 - \frac{v_0^2}{2g}\sin^2\theta_0$$

$$= y_0 + \frac{v_0^2}{2g}\sin^2\theta_0$$

Because $v_{y0} = v_0\ \sin\theta_0$, we can also write

$$H = y_0 + \frac{v_{y0}^2}{2g},$$

which is equation 3.24.

The range, R, of a projectile is defined as the horizontal distance between the launching point and the point where the projectile reaches the same height from which it started, $y(R) = y_0$. Inserting $x = R$ into equation 3.22:

$$y_0 = y_0 + R\ \tan\ \theta_0 - \frac{g}{2v_0^2\ \cos^2\ \theta_0}R^2$$

$$\Rightarrow \tan\ \theta_0 = \frac{g}{2v_0^2\ \cos^2\ \theta_0}R$$

$$\Rightarrow R = \frac{2v_0^2}{g}\sin\ \theta_0\ \cos\ \theta_0\ = \frac{v_0^2}{g}\sin\ 2\theta_0,$$

which is equation 3.25.

Note that the range, R, is twice the value of the x-coordinate, x_H, at which the trajectory reached its maximum height: $R = 2x_H$.

Finally, we consider how to maximize the range of the projectile. One way to maximize the range is to maximize the initial speed, v_0. Given a specific initial speed, what is the dependence of the range on the launch angle θ_0? To answer this question, we take the derivative of the range (equation 3.25) with respect to the launch angle:

$$\frac{dR}{d\theta_0} = \frac{d}{d\theta_0}\left(\frac{v_0^2}{g}\sin\ 2\theta_0\right) = 2\frac{v_0^2}{g}\cos\ 2\theta_0.$$

Then we set this derivative equal to zero and find the angle for which the maximum value is achieved. The angle between 0° and 90° for which $\cos\ 2\theta_0\ =\ 0$ is 45°. So the maximum range of an ideal projectile is given by

$$R_{max} = \frac{v_0^2}{g}. \qquad \textbf{(3.26)}$$

We could have obtained this result directly from the formula for the range because, according to that formula (equation 3.25), the range is at a maximum when sin $2\theta_0$ has its maximum value of 1, and it has this maximum when $2\theta_0 = 90^\circ$, or $\theta_0 = 45^\circ$.

Self-Test Opportunity 3.2

Another way to arrive at a formula for the range uses the fact that it takes just as much time for the projectile to reach the top of the trajectory as to come down, because of the symmetry of a parabola. We can calculate the time to reach the top of the trajectory, where $v_{y0} = 0$, and then multiply this time by 2 and then by the horizontal velocity component to arrive at the range. Can you derive the formula for calculating the range in this way?

Most sports involving balls provide numerous examples of projectile motion. We next consider a few examples where the effects of air resistance and spin do not dominate the motion, and so the findings are reasonably close to what happens in reality. In the next section, we'll look at what effects air resistance and spin can have on a projectile.

SOLVED PROBLEM 3.1 Throwing a Baseball

When listening to a radio broadcast of a baseball game, you often hear the phrase “line drive” or “frozen rope” for a ball hit really hard and at a low angle with respect to the ground. Some announcers even use “frozen rope” to describe a particularly strong throw from second or third base to first base. This figure of speech implies movement on a straight line—but we know that the ball’s actual trajectory is a parabola.

PROBLEM

What is the maximum height that a baseball reaches if it is thrown from second base to first base or from third base to first base, and in either case is released from a height of 6.0 ft, with a speed of 90. mph, and caught at the same height?

SOLUTION

THINK

The dimensions of a baseball infield are shown in Figure 3.12. (In this problem, we’ll need to perform lots of unit conversions. Generally, this book uses SI units, but baseball is full of British units.) The baseball infield is a square with sides 90. ft long. This is the distance between second and first base, and we get $d_{12} = 90.\ \text{ft} = 90. \cdot 0.3048\ \text{m} = 27.432\ \text{m}$. The distance from third to first base is the length of the diagonal of the infield square: $d_{13} = d_{12}\ \sqrt{2} = 38.795\ \text{m}$.

A speed of 90. mph (the speed of a good Major League fastball) translates into

$$v_0 = 90.\ \text{mph} = 90. \cdot 0.44704\ \text{m/s} = 40.2336\ \text{m/s}.$$

As with most trajectory problems, there are many ways to solve this problem. The most straightforward approach follows from our considerations of range and maximum height. We can equate the base-to-base distance with the range of the projectile because the ball is released and caught at the same height, $y_0 = 6.0\ \text{ft} = 6.0\ \text{ft} = 6.0 \cdot 0.3048\ \text{m} = 1.8288\ \text{m}$.

SKETCH

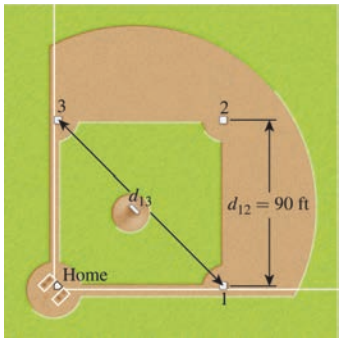

FIGURE 3.12
Dimensions of a baseball infield.

RESEARCH

In order to obtain the initial launch angle of the ball, we use equation 3.25, setting the range equal to the distance between first and second base:

$$d_{12} = \frac{v_0^2}{g}\sin 2\theta_0 \Rightarrow \theta_0 = \tfrac{1}{2}\sin^{-1}\left(\frac{d_{12}g}{v_0^2}\right).$$

Furthermore, we already have an equation for the maximum height:

$$H = y_0 + \frac{v_0^2 \ \sin^2\theta_0}{2g}$$

.

SIMPLIFY

Substituting our expression for the launch angle into the equation for the maximum height results in

$$H = y_0 + \frac{v_0^2 \ \sin^2\left(\tfrac{1}{2}\sin^{-1}\left(\dfrac{d_{12}g}{v_0^2}\right)\right)}{2g}$$

.

CALCULATE

We are ready to insert numbers:

$$H = 1.8288\ \text{m} + \frac{(40.2336\ \text{m/s})^2\ \sin^2\left(\frac{1}{2}\sin^{-1}\left(\frac{(27.432\ \text{m})}{(40.23}\right.\right.}{2\left(9.81\ \text{m/s}^2\right)}$$

ROUND

The precision of the given values was two significant digits. So we round our final result to

$$H = 2.4\ \text{m}.$$

Thus, a 90.-mph throw from second to first base is 2.40 m – 1.83 m = 0.57 m—that is, almost 2 ft—above a straight line at the middle of its trajectory. This number is even bigger for the throw from third to first base, for which we find an initial angle of 6.8° and a maximum height of 3.0 m, or 1.2 m (almost 4 ft) above the straight line connecting the points of release and catch (see Figure 3.13).

FIGURE 3.13 Trajectory of a baseball thrown from third to first base.

W. Bauer and G. D. Westfall

DOUBLE-CHECK

Common sense says that the longer throw from third to first needs to have a greater maximum height than the throw from second to first, and our answers agree with that. If you watch a baseball game from the stands or on television, these calculated heights may seem too large. However, if you watch a game from ground level, you'll see that the other infielders really do have to get some height on the ball to make a good throw to first base.

Let’s consider one more example from baseball and calculate the trajectory of a batted ball (see Figure 3.14).

FIGURE 3.14 Batting a baseball.

2011 Scott Cunningham/Getty Images

EXAMPLE 3.2 Batting a Baseball

During the flight of a batted baseball, in particular, a home run, air resistance has a quite noticeable impact. For now though, we want to neglect it. Section 3.5 will discuss the effect of air resistance.

PROBLEM

If the ball comes off the bat with a launch angle of 35.0° and an initial speed of 110 mph, how far will the ball fly? How long will it be in the air? What will its speed be at the top of its trajectory? What will its speed be when it lands?

Page 78

SOLUTION

Again, we need to convert to SI units first: $v_0 = 110 \text{ mph} = 49.2 \text{ m/s}$. We first find the range:

$$R = \frac{v_0^2}{g} \sin 2\theta_0 = \frac{(49.2 \text{ m/s})^2}{9.81 \text{ m/s}^2} \sin 70^\circ = 231.6 \text{ m}.$$

This distance is about 760 feet, which would be a home run in even the biggest ballpark. However, this calculation does not take air resistance into account. If we took friction due to air resistance into account, the distance would be reduced to approximately 400 feet. (See Section 3.5 on realistic projectile motion.)

In order to find the baseball's time in the air, we can divide the range by the horizontal component of the velocity, assuming the ball is hit at about ground level.

$$t = \frac{R}{v_0 \cos\theta_0} = \frac{231.5 \text{ m}}{(49.2 \text{ m/s})\ (\cos 35^\circ)} = 5.75 \text{ s}$$

.

Now we calculate the speeds at the top of the trajectory and at landing. At the top of the trajectory, the velocity has only a horizontal component, which is $v_0 \cos\theta_0 = 40.3 \text{ m/s}$. When the ball lands, we can calculate its speed using equation 3.23: $\left|\vec{v}\right| = \sqrt{v_0^2 - 2g(y - y_0)}$.

Because we assume that the altitude at which it lands is the same as the one from which it was launched, we see that the speed is the same at the landing point as at the launching point, 49.2 m/s.

A real baseball would not quite follow the trajectory calculated here. If instead we launched a small steel ball of the size of the baseball with the same angle and speed, neglecting air resistance would have led to a very good approximation, and the trajectory parameters just found would be verified in such an experiment. The reason we can comfortably neglect air resistance for the steel ball bearing is that it has a much higher mass density and smaller surface area than a baseball, so drag effects (which depend on cross-sectional area) are small compared to gravitational effects.

Concept Check 3.4

A projectile is launched from an initial height $y_0 = 0$. For a given launch angle, if the launch speed is doubled, what will happen to the range, *R*, and the time in the air, t_{air}?

a) *R* and t_{air} will both double.

b) *R* and t_{air} will both quadruple.

c) *R* will double, and t_{air} will stay the same.

d) *R* will quadruple, and t_{air} will double.

e) *R* will double, and t_{air} will quadruple.

Baseball is not the only sport that provides examples of projectile motion. Let's consider an example from football.

SOLVED PROBLEM 3.2 Hang Time

When a football team is forced to punt the ball away to the opponent, it is very important to kick the ball as far as possible but also to attain a sufficiently long hang time—that is, the ball should remain in the air long enough that the punt-coverage team has time to run downfield and tackle the receiver right after the catch.

PROBLEM

What are the initial angle and speed with which a football has to be punted so that its hang time is 4.41 s and it travels a distance of 49.8 m (= 54.5 yd)?

SOLUTION

THINK

A punt is a special case of projectile motion for which the initial and final values of the vertical coordinate are both zero. If we know the range of the projectile, we can figure out the hang time from the fact that the horizontal component of the velocity vector remains at a constant value; thus, the hang time must simply be the range divided by this horizontal component of the velocity vector. The equations for hang time and range give us two equations in the two unknown quantities that we are looking for: v_0 and θ_0.

SKETCH

This is one of the few cases in which a sketch does not seem to provide additional information.

RESEARCH

We have already seen (equation 3.25) that the range of a projectile is given by

$$R = \frac{v_0^2}{g} \sin\ 2\theta_0.$$

As already mentioned, the hang time can be most easily computed by dividing the range by the horizontal component of the velocity:

$$t = \frac{R}{v_0 \cos\theta_0}.$$

Thus, we have two equations in the two unknowns, v_0 and θ_0. (Remember, R and t were given in the problem statement.)

SIMPLIFY

We solve both equations for v_0^2 and set them equal:

$$\begin{aligned} R = \frac{v_0^2}{g}\sin 2\theta_0 \Rightarrow v_0^2 = \frac{gR}{\sin 2\theta_0} \searrow \\ t = \frac{R}{v_0 \cos\theta_0} \Rightarrow v_0^2 = \frac{R^2}{t^2 \cos^2\theta_0} \nearrow \end{aligned} \quad \frac{gR}{\sin 2\theta_0} = \frac{R^2}{t^2 \cos\theta_0}.$$

Now, we can solve for θ_0. Using $\sin 2\theta_0 = 2\sin\theta_0 \cos\theta_0$, we find

$$\begin{aligned} \frac{g}{2\sin\theta_0 \cos\theta_0} &= \frac{R}{t^2 \cos^2\theta_0} \\ \Rightarrow \tan\theta_0 &= \frac{gt^2}{2R} \\ \Rightarrow \theta_0 &= \tan^{-1}\left(\frac{gt^2}{2R}\right). \end{aligned}$$

Next, we substitute this expression in either of the two equations we started with. We select the equation for hang time and solve it for v_0:

$$t = \frac{R}{v_0 \cos\theta_0} \Rightarrow v_0 = \frac{R}{t \cos\theta_0}.$$

CALCULATE

All that remains is to insert numbers into the equations we have obtained:

$$\theta_0 = \tan^{-1}\left(\frac{\left(9.81\ \text{m/s}^2\right)(4.41\ \text{s})^2}{2(49.8\ \text{m})}\right) = 62.4331^\circ$$

$$v_0 = \frac{49.8\ \text{m}}{(4.41\ \text{s})(\cos\ 62.4331^\circ)} = 24.4013\ \text{m/s}.$$

ROUND

The range and hang time were specified to three significant figures, so we state our final results to this precision:

$$\theta_0 = 62.4^\circ$$

and

$$v_0 = 24.4\ \text{m/s}.$$

DOUBLE-CHECK

We know that the maximum range is reached with a launch angle of 45°. The punted ball here is launched at an initial angle that is significantly steeper, at 62.4°. Thus, the ball does not travel as far as it could go with the value of the initial speed that we computed. Instead, it travels higher and thus maximizes the hang time. If you watch good college or pro punters practice their skills during football games, you'll see that they try to kick the ball with an initial angle larger than 45°, in agreement with what we found in our calculations.

Concept Check 3.5

The same range as in Solved Problem 3.2 could be achieved with the same initial speed of 24.4 m/s but a launch angle different from 62.4°. What is the value of this angle?

a) 12.4°

b) 27.6°

c) 45.0°

d) 55.2°

Concept Check 3.6

What is the hang time for that other launch angle found in Concept Check 3.5?

a) 2.30 s

b) 3.14 s

c) 4.41 s

d) 5.14 s

SOLVED PROBLEM 3.3 Time of Flight

You may have participated in Science Olympiad during middle school or high school. In one of the events in Science Olympiad, the goal is to hit a horizontal target at a fixed distance with a golf ball launched by a trebuchet. Competing teams build their own trebuchets. Your team has constructed a trebuchet that is able to launch the golf ball with an initial speed of 17.2 m/s, according to extensive tests performed before the competition.

PROBLEM

If the target is located at the same height as the elevation from which the golf ball is released and at a horizontal distance of 22.42 m away, how long will the golf ball be in the air before it hits the target?

SOLUTION

THINK

Let's first eliminate what does not work. We cannot simply divide the distance between trebuchet and target by the initial speed, because this would imply that the initial velocity vector is in the horizontal direction. Since the projectile is in free fall in the vertical direction during its flight, it would certainly miss the target. So we have to aim the golf ball with an angle larger than zero relative to the horizontal. But at what angle do we need to aim?

If the golf ball, as stated, is released from the same height as the height of the target, then the horizontal distance between the trebuchet and the target is equal to the range. Because we also know the initial speed, we can calculate the release angle. Knowing the release angle and the initial speed lets us determine the horizontal component of the velocity vector. Since this horizontal component does not change in time, the flight time is simply given by the range divided by the horizontal component of the velocity.

SKETCH

We don't need a sketch at this point because it would simply show a parabola, as for all projectile motion. However, we do not know the initial angle yet, so we will need a sketch later.

RESEARCH

The range of a projectile is given by equation 3.25:

$$R = \frac{v_0^2}{g} \sin 2\theta_0.$$

If we know the value of this range and the initial speed, we can find the angle:

$$\sin 2\theta_0 = \frac{gR}{v_0^2}.$$

Once we have the value for the angle, we can use it to calculate the horizontal component of the initial velocity:

$$v_{x0} = v_0 \cos \theta_0.$$

Finally, as noted previously, we obtain the flight time as the ratio of the range and the horizontal component of the velocity:

$$t = \frac{R}{v_{x0}}.$$

SIMPLIFY

If we solve the equation for the angle, $\sin 2\theta_0 = Rg/v_0^2$, we see that it has two solutions: one for an angle of less than 45° and one for an angle of more than 45°. Figure 3.15 plots the function $\sin 2\theta_0$ (in red) for all possible values of the initial angle θ_0 and shows where that curve crosses the plot of Rg/v_0^2 (blue horizontal line). We call the two solutions θ_a and θ_b.

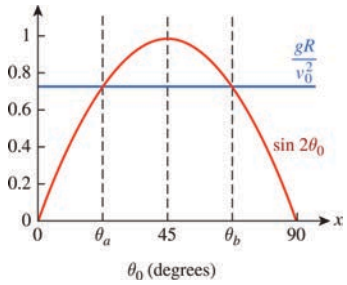

FIGURE 3.15 Two solutions for the initial angle.

Algebraically, these solutions are given as

$$\theta_{a,b} = \tfrac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right).$$

Substituting this result into the formula for the horizontal component of the velocity results in

$$t = \frac{R}{v_{x0}} = \frac{R}{v_0\ \cos\theta_0} = \frac{R}{v_0\ \cos\left(\frac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right)\right)}$$

.

CALCULATE

Inserting numbers, we find:

$$\theta_{a,b} = \frac{1}{2}\sin^{-1}\left(\frac{(22.42\ \text{m})\left(9.81\ \text{m/s}^2\right)}{(17.2\ \text{m/s})^2}\right) = 24.0128^\circ \text{ or } 65.9$$

$$t_a = \frac{R}{v_0\ \cos\ \theta_a} = \frac{22.42\ \text{m}}{(17.2\ \text{m/s})(\cos\ 24.0128^\circ)} = 1.42699\ \text{s}$$

$$t_b = \frac{R}{v_0\ \cos\ \theta_b} = \frac{22.42\ \text{m}}{(17.2\ \text{m/s})(\cos\ 65.9872^\circ)} = 3.20314\ \text{s}.$$

ROUND

The range was specified to four significant figures, and the initial speed to three. Therefore, we also state our final results to three significant figures:

$$t_a = 1.43\ \text{s}, \quad t_b = 3.20\ \text{s}.$$

Note that both solutions are valid in this case, and the team can select either one.

DOUBLE-CHECK

Back to the approach that does not work: simply taking the distance from the trebuchet to the target and dividing it by the speed. This incorrect procedure leads to $t_{\text{min}} = d/v_0 = 1.30\,\text{s}$. We use t_{min} to symbolize this value to indicate that it is some lower boundary representing the case in which the initial velocity vector points horizontally and in which we neglect the free-fall motion of the projectile. Thus, t_{min} serves as an absolute lower boundary, and it is reassuring to note that the shorter time we obtained above is a little larger than this lowest possible, but physically unrealistic, value.

3.5 Realistic Projectile Motion

If you are familiar with tennis or golf or baseball, you know that the parabolic model for the motion of a projectile is only a fairly crude approximation to the actual trajectory of any real ball. However, by ignoring some factors that affect real projectiles, we were able to focus on the physical principles that are most important in projectile motion. This is a common technique in science: Ignore some factors involved in a real situation in order to work with fewer variables and come to an understanding of the basic concept. Then go back and consider how the ignored factors affect the model. Let's briefly consider the most important factors that affect real projectile motion: air resistance, spin, and surface properties of the projectile.

The first modifying effect that we need to take into account is air resistance. Typically, we can parameterize air resistance as a velocity-dependent acceleration. The general analysis exceeds the scope of this book; however, the resulting trajectories are called *ballistic curves*.

Figure 3.16 shows the trajectories of baseballs launched at an initial angle of 35° with respect to the horizontal at initial speeds of 90 and 110 mph. Compare the trajectory shown for the launch speed of 110 mph with the result we calculated in Example 3.2: The real range of this ball is only slightly more than 400 ft, whereas we found 760 ft when we neglected air resistance. Obviously, for a long fly ball, neglecting air resistance is not valid.

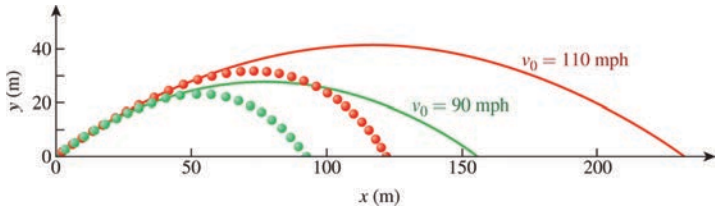

FIGURE 3.16 Trajectories of baseballs initially launched at an angle of 35° above the horizontal at speeds of 90 mph (green) and 110 mph (red). Solid curves neglect air resistance and backspin; dotted curves reflect air resistance and backspin.

Another important effect that the parabolic model neglects is the spin of the projectile as it moves through the air. When a quarterback throws a "spiral" in football, for example, the spin is important for the stability of the flight motion and prevents the ball from rotating end-over-end. In tennis, a ball with topspin drops much faster than a ball without noticeable spin, given the same initial values of speed and launch angle. Conversely, a tennis ball with underspin, or backspin, "floats" deeper into the court. In golf, backspin is sometimes desired, because it causes a steeper landing angle and thus helps the ball come to rest closer to its landing point than a ball hit without backspin. Depending on the magnitude and direction of rotation, sidespin of a golf ball can cause a deviation from a straight-line path along the ground (draws and fades for good players or hooks and slices for the rest of us).

In baseball, sidespin is what enables a pitcher to throw a curveball. By the way, there is no such thing as a "rising fastball" in baseball. However, balls thrown with severe backspin do not drop as fast as the batter expects and are thus sometimes perceived as rising—an optical illusion. In the graph of ballistic baseball trajectories in Figure 3.16, an initial backspin of 2000 rpm was assumed.

Curving and practically all other effects of spin on the trajectory of a moving ball are a result of the air molecules bouncing with higher speeds off the side of the ball (and the boundary layer of air molecules) that is rotating in the direction of the flight motion (and thus has a higher velocity relative to the incoming air molecules) than off the side of the ball rotating against the flight direction. We will return to this topic in Chapter 13 when we discuss fluid motion.

The surface properties of projectiles also have significant effects on their trajectories. Golf balls have dimples to make them fly farther. Balls that are otherwise identical to typical golf balls but have a smooth surface can be driven only about half as far. This surface effect is also the reason why sandpaper found in a pitcher's glove leads to ejection of that player from the game, because a baseball that is roughened on parts of its surface moves differently from one that is not.

Concept Check 3.7

Looking at Figure 3.16, what can you say about the ratio R_{real}/R_{ideal}, the real projectile range divided by the range calculated for ideal projectile motion?

a) For the launch angle of 35°, the ratio *in*creases with the launch speed.

b) For the launch angle of 35°, the ratio *de*creases with the launch speed.

c) The ratio is independent of the launch speed.

d) For all launch angles, the ratio *in*creases with the launch speed.

e) For all launch angles, the ratio *de*creases with the launch speed.

3.6 Relative Motion

To study motion, we have allowed ourselves to shift the origin of the coordinate system by properly choosing values for x_0 and y_0. In general, x_0 and y_0 are constants that can be chosen freely. If this choice is made intelligently, it can help make a problem more manageable. For example, when we calculated the path of the projectile, $y(x)$, we set $x_0 = 0$ to simplify our calculations. The freedom to select values for x_0 and y_0 arises from the fact that our ability to describe any kind of motion does not depend on the location of the origin of the coordinate system.

So far, we have examined physical situations where we have kept the origin of the coordinate system at a fixed location during the motion of the object we wanted to consider. However, in some physical situations, it is impractical to choose a reference system with a fixed origin. Consider, for example, a jet plane landing on an aircraft carrier that is going forward at full throttle at the same time. You want to describe the plane's motion in a coordinate system fixed to the carrier, even though the carrier is moving. The reason why this is important is that the plane needs to come to rest *relative* to the carrier at some fixed location on the deck. The reference frame from which we view motion makes a big difference in how we describe the motion, producing an effect known as **relative velocity**.

Another example of a situation for which we cannot neglect relative motion is a transatlantic flight from Detroit, Michigan, to Frankfurt, Germany, which takes 8 h and 10 min. Using the same aircraft and going in the reverse direction, from Frankfurt to Detroit, takes 9 h and 10 min, a full hour longer. The primary reason for this difference is that the prevailing wind at high altitudes, the jet stream, tends to blow from west to east at speeds as high as 67 m/s (150 mph). Even though the airplane's speed relative to the air around it is the same in both directions, that air is moving with its own speed. Thus, the relationship of the coordinate system of the air inside the jet stream to the coordinate system in which the locations of Detroit and Frankfurt remain fixed is important in understanding the difference in flight times.

For a more easily analyzed example of a moving coordinate system, let's consider motion on a moving walkway, as is typically found in airport terminals. This system is an example of one-dimensional relative motion. Suppose that the walkway surface moves with a certain velocity, v_{wt}, relative to the terminal. We use the subscripts w for walkway and t for terminal. Then a coordinate system that is fixed to the walkway surface

has exactly velocity v_{wt} relative to a coordinate system attached to the terminal. The man shown in Figure 3.17 is walking with a velocity v_{mw} as measured in a coordinate system on the walkway, and he has a velocity $v_{\text{mt}} = v_{\text{mw}} + v_{\text{wt}}$ with respect to the terminal. The two velocities v_{mw} and v_{wt} add as vectors since the corresponding displacements add as vectors. (We will show this explicitly when we generalize to three dimensions.) For example, if the walkway moves with $v_{\text{wt}} = 1.5\ \text{m/s}$ and the man moves with $v_{\text{mw}} = 2.0\ \text{m/s}$, then he will progress through the terminal with a velocity of $v_{\text{mt}} = v_{\text{mw}} + v_{\text{wt}} = 2.0\ \text{m/s} + 1.5\ \text{m/s} = 3.5\ \text{m/s}$.

FIGURE 3.17 Man walking on a moving walkway, demonstrating one-dimensional relative motion.

W. Bauer and G. D. Westfall

One can achieve a state of no motion relative to the terminal by walking in the direction opposite of the motion of the walkway with a velocity that is exactly the negative of the walkway velocity. Children often try to do this. If a child were to walk with $v_{\text{mw}} = 1.5\ \text{m/s}$ on this walkway, her velocity would be zero relative to the terminal.

It is essential for this discussion of relative motion that the two coordinate systems have a velocity relative to each other that is constant in time. In this case, we can show that the accelerations measured in both coordinate systems are identical: $v_{\text{wt}} = \text{const.} \Rightarrow dv_{\text{wt}}/dt = 0$. From $v_{\text{mt}} = v_{\text{mw}} + v_{\text{wt}}$, we then obtain:

$$\frac{dv_{\text{mt}}}{dt} = \frac{d(v_{\text{mw}} + v_{\text{wt}})}{dt} = \frac{dv_{\text{mw}}}{dt} + \frac{dv_{\text{wt}}}{dt} = \frac{dv_{\text{mw}}}{dt} + 0 \tag{3.27}$$
$$\Rightarrow a_{\text{mt}} = a_{\text{mw}}.$$

Therefore, the accelerations measured in both coordinate systems are indeed the same. This type of velocity addition is also known as a **Galilean transformation**. Before we go on to the two- and three-dimensional cases, note that this type of transformation is valid only for speeds that are small compared to the speed of light. Once the speed approaches the speed of light, we must use a different transformation, which we discuss in detail in Chapter 35 on the theory of relativity.

Now let's generalize this result to more than one spatial dimension. We assume that we have two coordinate systems: x_l, y_l, z_l and x_m, y_m, z_m.(Here we use the subscripts l for the coordinate system that is at rest in the laboratory and m for the one that is moving.) At time t = 0, suppose the origins of both coordinate systems are located at the same point, with their axes exactly parallel to one another. As indicated in Figure 3.18, the origin of the moving $x_\mathrm{m}y_\mathrm{m}z_\mathrm{m}$ coordinate system moves with a constant translational velocity $\vec{v}_\mathrm{ml}$ (blue arrow) relative to the origin of the laboratory $x_1y_1z_1$ coordinate system. After a time t, the origin of the moving $x_\mathrm{m}y_\mathrm{m}z_\mathrm{m}$ coordinate system is thus located at the point $\vec{r}_\mathrm{ml} = \vec{v}_\mathrm{ml}t$.

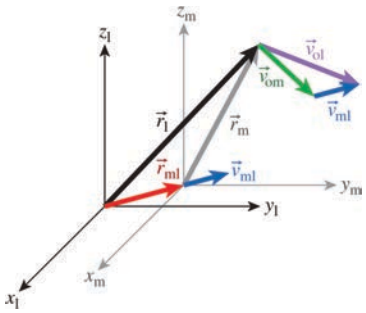

FIGURE 3.18
Reference frame transformation of a velocity vector and a position vector at some particular time.

We can now describe the motion of any object in either coordinate system. If the object is located at coordinate $\vec{r}_1$ in the $x_1y_1z_1$ coordinate

system and at coordinate $\overrightarrow{r_m}$ in the $x_{\mathrm{m}}y_{\mathrm{m}}z_{\mathrm{m}}$ coordinate system, then the position vectors are related to each other via simple vector addition:

$$\overrightarrow{r_1} = \overrightarrow{r_{\mathrm{m}}} + \overrightarrow{r_{\mathrm{ml}}} = \overrightarrow{r_{\mathrm{m}}} + \overrightarrow{v_{\mathrm{ml}}}t \qquad \textbf{(3.28)}$$

.

A similar relationship holds for the object's velocities, as measured in the two coordinate systems. If the object has velocity $\overrightarrow{v_{\mathrm{ol}}}$ in the $x_1y_1z_1$ coordinate system and velocity $\overrightarrow{v_{\mathrm{om}}}$ in the $x_my_mz_m$ coordinate system, these two velocities are related via:

$$\overrightarrow{v_{\mathrm{ol}}} = \overrightarrow{v_{\mathrm{om}}} + \overrightarrow{v_{\mathrm{ml}}} \qquad \textbf{(3.29)}$$

This equation can be obtained by taking the time derivative of equation 3.28, because $\overrightarrow{v_{\mathrm{ml}}}$ is constant. Note that the two inner subscripts on the right-hand side of this equation are the same (and will be in any application of this equation). This makes the equation understandable on an intuitive level, because it says that the velocity of the *o*bject in the *l*ab frame (subscript "ol") is equal to the sum of the velocity with which the *o*bject moves relative to the *m*oving frame (subscript "om") and the velocity with which the *m*oving frame moves relative to the *l*ab frame (subscript "ml").

Taking another time derivative produces the accelerations. Again, because $\overrightarrow{v_{\mathrm{ml}}}$ is constant and thus has a derivative equal to zero, we obtain, just as in the one-dimensional case,

$$\overrightarrow{a_{\mathrm{ol}}} = \overrightarrow{a_{\mathrm{om}}}. \qquad \textbf{(3.30)}$$

The magnitude and direction of the acceleration for an object is the same in both coordinate systems.

EXAMPLE 3.3 Airplane in a Crosswind

Airplanes move relative to the air that surrounds them. Suppose a pilot points his plane in the northeast direction. The airplane moves with a speed of 160. m/s relative to the wind, and the wind is blowing at 32.0 m/s in a direction from east to west (measured by an instrument at a fixed point on the ground).

PROBLEM

What is the velocity vector—speed and direction—of the airplane relative to the ground? How far off course does the wind blow this plane in 2.0 h?

SOLUTION

Figure 3.19 shows a vector diagram of the velocities. The airplane heads in the northeast direction, and the yellow arrow represents its velocity vector relative to the wind. The velocity vector of the wind is represented in orange and points due west. Graphical vector addition results in the green arrow that represents the velocity of the plane relative to the ground. To solve this problem, we apply the basic transformation of equation 3.29 embodied in the equation

$$\vec{v}_{\text{pg}} = \vec{v}_{\text{pw}} + \vec{v}_{\text{wg}}.$$

FIGURE 3.19 Velocity of an airplane with respect to the wind (yellow), the velocity of the wind with respect to the ground (orange), and the resultant velocity of the airplane with respect to the ground (green).

Here $\overrightarrow{v}_{\text{pw}}$ is the velocity of the plane with respect to the wind and has these components:

$$v_{\text{pw,x}} = v_{\text{pw}} \cos\theta = 160 \text{ m/s} \cdot \cos 45^\circ = 113 \text{ m/s}$$
$$v_{\text{pw,y}} = v_{\text{pw}} \sin\theta = 160 \text{ m/s} \cdot \sin 45^\circ = 113 \text{ m/s}$$

.

The velocity of the wind with respect to the ground $\overrightarrow{v}_{\text{wg}}$, has these components:

$$v_{\text{wg,x}} = -32 \text{ m/s}$$
$$v_{\text{wg,y}} = 0.$$

We next obtain the components of the airplane's velocity relative to a coordinate system fixed to the ground, $\overrightarrow{v}_{\text{pg}}$:

$$v_{\text{pg,x}} = v_{\text{pw,x}} + v_{\text{wg,x}} = 113 \text{ m/s} - 32 \text{ m/s} = 81 \text{ m/s}$$
$$v_{\text{pg,y}} = v_{\text{pw,y}} + v_{\text{pw,y}} = 113 \text{ m/s}.$$

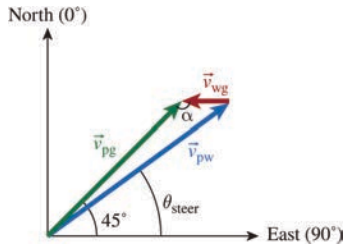
The absolute value of the velocity vector and its direction in the ground-based coordinate system are therefore

$$v_{\text{pg}} = \sqrt{v_{\text{pg,x}}^2 + v_{\text{pg,y}}^2} = 139 \text{ m/s}$$
$$\theta = \tan^{-1}\left(\frac{v_{\text{pg,y}}}{v_{\text{pg,x}}}\right) = 54.4^\circ.$$

Now we need to find the course deviation due to the wind. To find this quantity, we can multiply the plane's velocity vectors in each coordinate system by the elapsed time of 2 h = 7200 s, then take the vector difference, and finally obtain the magnitude of the vector difference. The answer can be obtained more easily if we use equation 3.29 multiplied by the elapsed time to reflect that the course deviation, $\vec{r}_{\text{T}}$, due to the wind is the wind velocity, $\vec{v}_{\text{wg}}$, times 7200 s:

$$\left|\vec{r}_{\text{T}}\right| = \left|\vec{v}_{\text{wg}}\right| t = 32.0 \text{ m/s} \cdot 7200 \text{ s} = 230.4 \text{ km}$$

Normally the pilot would not allow the plane to be blown off course by the wind. Let's calculate the heading on the compass of the plane that the pilot would have to fly to maintain a ground path in the northeast direction. The wind is moving toward the pilot's left so he will have to steer to the right to maintain a ground path in the northeast direction. The plane will still be flying with a speed of 160. m/s with respect to the wind. In the drawing, the direction that the pilot must steer is given by θ_{steer} and the angle between $\vec{v}_{\text{pg}}$ and $\vec{v}_{\text{wg}}$ is α.



We can use the law on sines to get

$$\frac{v_{\text{wg}}}{\sin(45.0^\circ - \theta_{\text{steer}})} =. \frac{v_{\text{pw}}}{\sin\ \alpha}$$

The interior angles of a triangle sum to 180° so

$$(45.0^\circ - \theta_{\text{steer}}) + \theta_{\text{steer}} + \alpha = 180^\circ$$
$$\alpha = 180^\circ - 45.0^\circ = 135^\circ.$$

We can then solve for θ_{steer}

$$\sin(45.0^\circ - \theta_{\text{steer}}) = \frac{v_{\text{wg}} \sin\alpha}{v_{\text{pw}}}$$
$$\theta_{\text{steer}} = 45.0^\circ - \sin^{-1}\frac{v_{\text{wg}} \sin\alpha}{v_{\text{pw}}}$$
$$\theta_{\text{steer}} = 45.0^\circ - \sin^{-1}\frac{(20.0\ \text{m/s})\sin 135^\circ}{160.\ \text{m/s}} = 39.9^\circ.$$

So the pilot must steer a course on his compass of $90.0^\circ - 39.9^\circ = 50.1^\circ$ to maintain a path along the ground in a northeast direction.

DISCUSSION

The Earth itself moves a considerable amount in 2 h, as a result of its own rotation and its motion around the Sun, and you might think we have to take these motions into account. That the Earth moves is true, but is irrelevant for the present example: The airplane, the air, and the ground all participate in this rotation and orbital motion, which is superimposed on the relative motion of the objects described in the problem. Thus, we simply perform our calculations in a coordinate system in which the Earth is at rest and not rotating.

Another interesting consequence of relative motion can be seen when observing rain while in a moving car. You may have wondered why the rain always seems to come almost straight at you as you are driving. The following example answers this question.

Concept Check 3.8

It is raining, and there is practically no wind. While driving through the rain, you speed up. What happens to the angle of the rain relative to the horizontal that you observe from inside the car?

a) It *in*creases.

b) It *de*creases.

c) It stays the same.

d) It can increase or decrease, depending on the direction in which you are driving.

EXAMPLE 3.4 Driving through Rain

Let's supppose rain is falling straight down on a car, as indicated by the white lines in Figure 3.20. A stationary observer outside the car would be able to measure the velocities of the rain (blue arrow) and of the moving car (red arrow).

FIGURE 3.20 The velocity vectors of a moving car and of rain falling straight down on the car, as viewed by a stationary observer.

However, if you are sitting inside the moving car, the outside world of the stationary observer (including the street, as well as the rain) moves with a relative velocity of $\overrightarrow{v} = -\overrightarrow{v}_{\text{car}}$ The velocity of this relative motion has to be added to all outside events as observed from inside the moving car. This motion results in a velocity vector $\overrightarrow{v\prime}_{\text{rain}}$ for the rain as observed from inside the moving car (Figure 3.21); mathematically, this vector is a sum, $\overrightarrow{v\prime}_{\text{rain}} = \overrightarrow{v}_{\text{rain}} - \overrightarrow{v}_{\text{car}}$ where $\overrightarrow{v}_{\text{rain}}$ and $\overrightarrow{v}_{\text{car}}$ are the velocity vectors of the rain and the car as observed by the stationary observer.

FIGURE 3.21 The velocity vector $\overrightarrow{vl}_{\text{rain}}$ of rain, as observed from inside the moving car.

SOLVED PROBLEM 3.4 Moving Deer

The zookeeper who captured the monkey in Example 3.1 now has to capture a deer. We found that she needed to aim directly at the monkey for that earlier capture. She decides to fire directly at her target again, indicated by the bull's-eye in Figure 3.22.

FIGURE 3.22 The red arrow indicates the velocity of the deer in the zookeeper's reference frame.

David Ponton/age fotostock

PROBLEM

Where will the tranquilizer dart hit if the deer is $d = 25$ m away from the zookeeper and running from her right to her left with a speed of $v_d = 3.0\ \mathrm{m/s}$? The tranquilizer dart leaves her rifle horizontally with a speed of $v_0 = 90.\ \mathrm{m/s}$.

SOLUTION

THINK

The deer is moving at the same time as the dart is falling, which introduces two complications. It is easiest to think about this problem in the moving reference frame of the deer. In that frame, the sideways horizontal component of the dart's motion has a constant velocity of $-\vec{v}_d$ The vertical component of the motion is a free-fall motion. The total displacement of the dart is then the vector sum of the displacements caused by both of these motions.

SKETCH

We draw the two displacements in the reference frame of the deer (Figure 3.23). The blue arrow is the displacement due to the free-fall motion, and the red arrow is the sideways horizontal motion of the dart in the reference frame of the deer. The advantage of drawing the displacements in this moving reference frame is that the bull's-eye is attached to the deer and is moving with it.

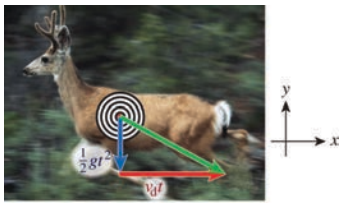


FIGURE 3.23
Displacement of the tranquilizer dart in the deer's reference frame.

David Ponton/age fotostock

RESEARCH

First, we need to calculate the time it takes the tranquilizer dart to move 25 m in the direct line of sight from the gun to the deer. Because the dart leaves the rifle in the horizontal direction, the initial forward horizontal component of the dart's velocity vector is 90. m/s. For projectile motion, the horizontal velocity component is constant. Therefore, for the time the dart takes to cross the 25-m distance, we have

$$t = \frac{d}{v_0}.$$

During this time, the dart falls under the influence of gravity, and this vertical displacement is

$$\Delta y = -\frac{1}{2}gt^2.$$

Also, during this time, the deer has a sideways horizontal displacement in the reference frame of the zookeeper of $x = -v_d t$ (the deer moves to the left, hence the negative value of the horizontal

velocity component). Therefore, the displacement of the dart in the reference frame of the deer is (see Figure 3.23)

$$\Delta x = v_{\mathrm{d}} t.$$

SIMPLIFY

Substituting the expression for the time into the equations for the two displacements results in

$$\Delta x = v_{\mathrm{d}} = d\frac{d}{v_0}\frac{v_{\mathrm{d}}}{v_0}$$
$$\Delta y = -\frac{1}{2}gt^2 = -.\frac{d^2 g}{2v_0^2}$$

CALCULATE

We are now ready to put in the numbers:

$$\Delta x = \frac{(3.0\ \mathrm{m/s})}{(90.\ \mathrm{m/s})}(25\ \mathrm{m}) = 0.833333\ \mathrm{m}$$
$$\Delta y = -\frac{(25\ \mathrm{m})^2\ (9.81\ \mathrm{m/s})^2}{2(90.\ \mathrm{m/s})^2} = -0.378472\ \mathrm{m}.$$

ROUND

Rounding our results to two significant figures gives:

$$\Delta x = 0.83\ \mathrm{m}.$$
$$\Delta y = -0.38\ \mathrm{m}.$$

The net effect is the vector sum of the sideways horizontal and vertical displacements, as indicated by the green diagonal arrow in Figure 3.23: The dart will miss the deer and hit the ground behind the deer.

DOUBLE-CHECK

Where should the zookeeper aim? If she wants to hit the running deer, she has to aim approximately 0.38 m above and 0.83 m to the left of her intended target. A dart fired in this direction will hit the

deer, but not in the center of the bull's-eye. Why? With this aim, the initial velocity vector does not point in the horizontal direction. This lengthens the flight time, as we saw in Solved Problem 3.3. A longer flight time translates into a larger displacement in both x- and y-directions. This correction is small, but calculating it is a bit too involved to show here.

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- In two or three dimensions, any change in the magnitude or direction of an object's velocity corresponds to acceleration.
- Projectile motion of an object can be separated into motion in the x-direction, described by the equations

$$(1) \quad x = x_0 + v_{x0}t$$
$$(2) \quad v_x = v_{x0}$$

and motion in the y-direction, described by

$$(3) \quad y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2$$
$$(4) \quad y = y_0 + \overline{v}_y t$$
$$(5) \quad v_y = v_{y0} - gt$$
$$(6) \quad \overline{v}_y = \tfrac{1}{2}(v_y + v_{y0})$$
$$(7) \quad {v^2}_y = v_{y0}^2 - 2g(y - y_0)$$

- The relationship between the x- and y-coordinates for ideal projectile motion can be described by a parabola given by the formula $y = y_0 + (\tan\ \theta_0)x - \dfrac{g}{2v_0^2\ \cos^2\ \theta_0}x^2$, where y_0 is the initial vertical position, v_0 is the initial speed of the projectile, and θ_0 is the initial angle with respect to the horizontal at which the projectile is launched.
- The range R of an ideal projectile is given by

$$R = \frac{v_0^2}{g}\sin 2\theta_0.$$

- The maximum height H reached by an ideal projectile is given by $H = y_0 + \dfrac{v_{y0}^2}{2g}$ where v_{y0} is the vertical component of the initial velocity.
- Projectile trajectories are not parabolas when air resistance is taken into account. In general, the trajectories of realistic

projectiles do not reach the maximum predicted height, and they have a significantly shorter range.

- The velocity $\overrightarrow{v_{\mathrm{ol}}}$ of an object with respect to a stationary laboratory reference frame can be calculated using a Galilean transformation of the velocity, $\overrightarrow{v_{\mathrm{ol}}} = \overrightarrow{v_{\mathrm{om}}} + \overrightarrow{v_{\mathrm{ml}}}$ where $\overrightarrow{v_{\mathrm{om}}}$ is the velocity of the object with respect to a moving reference frame and $\overrightarrow{v_{\mathrm{ml}}}$ is the constant velocity of the moving reference frame with respect to the laboratory frame.

ANSWERS TO SELF-TEST OPPORTUNITIES

3.1 Use equation 3.23 and $t = (x - x_0)/v_{x0} = (x - x_0)/(v_0 \cos\theta_0)$ to find

$$\left|\vec{v}\right| = \sqrt{v_0^2 - 2g(x - x_0)(\tan\theta_0) + g^2(x - x_0)^2/(v_0 \cos\theta_0)^2}$$

3.2 The time to reach the top is given by $v_y = v_{y0} - gt_{\text{top}} = 0 \Rightarrow t_{\text{top}} = v_{y0}/g = v_0 \sin\theta_0/g$. The total flight time is $t_{\text{total}} = 2t_{\text{top}}$ because of the symmetry of the parabolic projectile trajectory. The range is the product of the total flight time and the horizontal velocity component: $R = t_{\text{total}} v_{x0} = 2t_{\text{top}} v_0 \cos\theta_0 = 2(v_0 \sin\theta_0/g)v_0 \cos\theta_0 = v_0^2 \sin(2\theta_0)/g$.

PROBLEM-SOLVING GUIDELINES

1. In all problems involving moving reference frames, it is important to clearly distinguish which object has what motion in which frame and relative to what. It is convenient to use subscripts consisting of two letters, where the first letter stands for a particular object and the second letter for the object it is moving relative to. The moving walkway situation discussed in Section 3.6 provides a good example of this use of subscripts.

2. In all problems concerning ideal projectile motion, the motion in the *x*-direction is independent of that in the *y*-direction. To solve these, you can often use the seven kinematical equations (3.11 through 3.17), which describe motion with constant velocity in the horizontal direction and free-fall motion with constant acceleration in the vertical direction. In general, you should avoid cookie-cutter–style application of formulas, but in exam situations, these seven kinematical equations can be your first line of defense. Keep in mind, however, that these equations work only in situations in which the horizontal acceleration component is zero and the vertical acceleration component is constant.

MULTIPLE-CHOICE QUESTIONS

3.1 An arrow is shot horizontally with a speed of 20. m/s from the top of a tower 60. m high. The time to reach the ground will be

a) 8.9 s.

b) 7.1 s.

c) 3.5 s.

d) 2.6 s.

e) 1.0 s.

3.2 A projectile is launched from the top of a building with an initial velocity of 30.0 m/s at an angle of 60.0° above the horizontal. The magnitude of its velocity at t = 5.00 s after the launch is

a) -23.0 m/s.

b) 7.3 m/s.

c) 15.0 m/s.

d) 27.5 m/s.

e) 50.4 m/s.

3.3 A ball is thrown at an angle between 0° and 90° with respect to the horizontal. Its velocity and acceleration vectors are parallel to each other at a launch angle of

a) 0°.

b) 45°.

c) 60°.

d) 90°.

e) none of the above.

3.4 During practice two baseball outfielders throw a ball to the shortstop. In both cases the distance is 40.0 m. Outfielder 1 throws the ball with an initial speed of 20.0 m/s, outfielder 2 throws the ball with an initial speed of 30.0 m/s. In both cases the balls are thrown and caught at the same height above ground.

a) Ball 1 is in the air for a shorter time than ball 2.

b) Ball 2 is in the air for a shorter time than ball 1.

c) Both balls are in the air for the same duration.

d) The answer cannot be decided from the information given.

3.5 A 50-g ball rolls off a countertop and lands 2 m from the base of the counter. A 100-g ball rolls off the same countertop with the same speed. It lands _____ from the base of the counter.

a) less than 1 m

b) 1 m

c) 2 m

d) 4 m

e) more than 4 m

3.6 For a given initial speed of an ideal projectile, there is (are) _____ launch angle(s) for which the range of the projectile is the same.

a) only one

b) two different

c) more than two but a finite number of

d) only one if the angle is 45° but otherwise two different

e) an infinite number of

3.7 A cruise ship moves southward in still water at a speed of 20.0 km/h, while a passenger on the deck of the ship walks toward the east at a speed of 5.0 km/h. The passenger's velocity with respect to Earth is

a) 20.6 km/h, at an angle of 14.04° east of south.

b) 20.6 km/h, at an angle of 14.04° south of east.

c) 25.0 km/h, south.

d) 25.0 km/h, east.

e) 20.6 km/h, south.

3.8 Two cannonballs are shot from different cannons at angles $\theta_{01} = 20^\circ$ and $\theta_{02} = 30^\circ$, respectively. Assuming ideal projectile motion, the ratio of the launching speeds, v_{02}/v_{01}, for which the two cannonballs achieve the same range is

a) 0.742.

b) 0.862.

c) 1.212.

d) 1.093.

e) 2.222.

3.9 The acceleration due to gravity on the Moon is $1.62\ \mathrm{m/s^2}$, approximately a sixth of the value on Earth. For a given initial velocity v_0 and a given launch angle θ_0, the ratio of the range of an ideal projectile on the Moon to the range of the same projectile on Earth, $R_{\mathrm{Moon}}/R_{\mathrm{Earth}}$, will be approximately

a) 6.

b) 3.

c) 12.

d) 5.

e) 1.

3.10 A baseball is launched from the bat at an angle $\theta_0 = 30.0^\circ$ with respect to the positive *x*-axis and with an initial speed of 40.0 m/s, and it is caught at the same height from which it was hit. Assuming ideal projectile motion (positive *y*-axis upward), the velocity of the ball when it is caught is

a) $\left(20.00\ \widehat{x} + 34.64\ \hat{y}\right)\ \mathrm{m/s}$.

b) $\left(-20.00\ \widehat{x} + 34.64\ \hat{y}\right)\ \mathrm{m/s}$.

c) $\left(34.64\ \widehat{x} - 20.00\ \hat{y}\right)\ \mathrm{m/s}$.

d) $\left(34.64\ \widehat{x} + 20.00\ \hat{y}\right)\ \mathrm{m/s}$.

3.11 In ideal projectile motion, the velocity and acceleration of the projectile at its maximum height are, respectively,

a) horizontal, vertical downward.

b) horizontal, zero.

c) zero, zero.

d) zero, vertical downward.

e) zero, horizontal.

3.12 In ideal projectile motion, when the positive *y*-axis is chosen to be vertically upward, the *y*-component of the acceleration of the object during the ascending part of the motion and the *y*-component of the acceleration during the descending part of the motion are, respectively,

a) positive, negative.

b) negative, positive.

c) positive, positive.

d) negative, negative.

3.13 In ideal projectile motion, when the positive y-axis is chosen to be vertically upward, the y-component of the velocity of the object during the ascending part of the motion and the y-component of the velocity during the descending part of the motion are, respectively,

a) positive, negative.

b) negative, positive.

c) positive, positive.

d) negative, negative.

3.14 A projectile is launched from a height $y_0 = 0$. For a given launch angle, if the launch speed is doubled, what will happen to the range R and the maximum height H of the projectile?

a) R and H will both double.

b) R and H will both quadruple.

c) R will double, and H will stay the same.

d) R will quadruple, and H will double.

e) R will double, and H will quadruple.

3.15 A projectile is launched twice from a height $y_0 = 0$ at a given launch speed, v_0. The first launch angle is 30.0°; the second angle is 60.0°. What can you say about the range R of the projectile in these two cases?

a) R is the same for both cases.

b) R is larger for a launch angle of 30.0°.

c) R is larger for a launch angle of 60.0°.

d) None of the preceding statements are true.

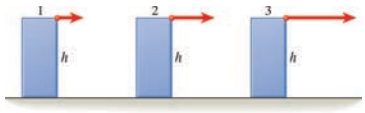
CONCEPTUAL QUESTIONS

3.16 A ball is thrown from ground at an angle between 0° and 90°. Which of the following remain constant: x, y, v_x, v_y, a_x, a_y?

3.17 A ball is thrown straight up by a passenger in a train that is moving with a constant velocity. Where would the ball land—back in his hands, in front of him, or behind him? Does your answer change if the train is accelerating in the forward direction? If yes, how?

3.18 A rock is thrown at an angle 45° below the horizontal from the top of a building. Immediately after release will its acceleration be greater than, equal to, or less than the acceleration due to gravity?

3.19 Three balls of different masses are thrown horizontally from the same height with different initial speeds, as shown in the figure. Rank in order, from the shortest to the longest, the times the balls take to hit the ground.



3.20 To attain maximum height for the trajectory of a projectile, what angle would you choose between 0° and 90°, assuming that you can launch the projectile with the same initial speed independent of the launch angle. Explain your reasoning.

3.21 An airplane is traveling at a constant horizontal speed v, at an altitude h above a lake, when a trapdoor at the bottom of the airplane opens and a package is released (falls) from the plane. The airplane continues horizontally at the same altitude and velocity. Neglect air resistance.

a) What is the distance between the package and the plane when the package hits the surface of the lake?

b) What is the horizontal component of the velocity vector of the package when it hits the lake?

c) What is the speed of the package when it hits the lake?

3.22 Two cannonballs are shot in sequence from a cannon, into the air, with the same muzzle velocity, at the same launch angle. Based on their trajectory and range, how can you tell which one is made of lead and which one is made of wood. If the same cannonballs were launched in vacuum, what would your answer be?

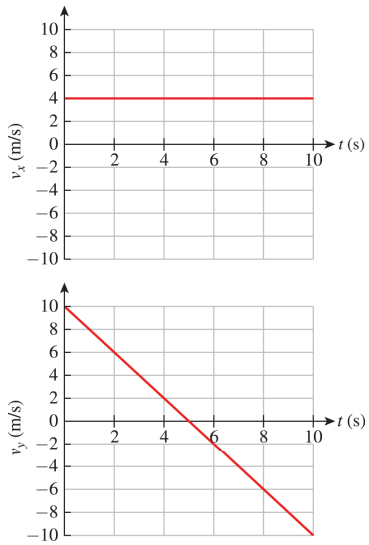
3.23 One should never jump off a moving vehicle (train, car, bus, etc.). Assuming, however, that one does perform such a jump, from a physics standpoint, what would be the best direction to jump in order to minimize the impact of the landing? Explain.

3.24 A boat travels at a speed of v_{BW} relative to the water in a river of width D. The speed at which the water is flowing is v_{W}.

a) Prove that the time required to cross the river to a point exactly opposite the starting point and then to return is $T_1 = 2D/\sqrt{v_{\mathrm{BW}}^2 - v_{\mathrm{W}}^2}$.

b) Prove that the time for the boat to travel a distance D downstream and then return is $T_1 = 2Dv_{BW}/\left(v^2{}_{BW} - v^2{}_{W}\right)$.

3.25 A rocket-powered hockey puck is moving on a (frictionless) horizontal air-hockey table. The x- and y-components of its velocity as a function of time are presented in the graphs below. Assuming that at t = 0 the puck is at (x_0, y_0) = (1, 2), draw a detailed graph of the trajectory $y(x)$.



3.26 For a certain object in three-dimensional motion, the x-, y-, and z-coordinates as a function of time are given by

$$x(t) = \frac{\sqrt{2}}{2}t,\ y(t) = \frac{\sqrt{2}}{2}t,\ \text{and}\ z(t) = -4.9t^2 + \sqrt{3}t.$$

Describe the motion and the trajectory of the object in an *xyz* coordinate system.

3.27 An object moves in the *xy*-plane. The *x*- and *y*-coordinates of the object as a function of time are given by the following equations: $x(t) = 4.9t^2 + 2t + 1$ and $y(t) = 3t + 2$. What is the velocity vector of the object as a function of time? What is its acceleration vector at the time $t = 2$ s?

3.28 A particle's motion is described by the following two parametric equations:

$$x(t) = 5\ \cos(2\pi t)$$
$$y(t) = 5\ \sin(2\pi t)$$

where the displacements are in meters and *t* is the time, in seconds.

a) Draw a graph of the particle's trajectory (that is, a graph of *y* versus *x*).

b) Determine the equations that describe the *x*- and *y*-components of the *velocity*, v_x and v_y, as functions of time.

c) Draw a graph of the particle's speed as a function of time.

3.29 In a proof-of-concept experiment for an antiballistic missile defense system, a missile is fired from the ground of a shooting range toward a stationary target on the ground. The system detects the missile by radar, analyzes in real time its parabolic motion, and determines that it was fired from a distance $x_0 = 5.00\,\text{km}$, with an initial speed of 0.600 km/s in the *xz*-plane such that the *x*-component of the initial velocity is in the negative *x*-direction, and with a launch angle $\theta_0 = 20.0^\circ$. The defense system then calculates the required time delay measured from the launch of the missile and fires a small rocket situated at $y_0 = -1.00$ km with an initial velocity of v_r m/s at a launch angle $\alpha_0 = 60.0^\circ$ in the *yz*-plane, to intercept the missile. Determine the initial speed v_r of the intercept rocket and the required time delay.

3.30 A projectile is launched at an angle of 45.0° above the horizontal. What is the ratio of its horizontal range to its maximum height? How does the answer change if the initial speed of the projectile is doubled?

3.31 In a projectile motion, the horizontal range and the maximum height attained by the projectile are equal.

a) What is the launch angle?

b) If everything else stays the same, how should the launch angle, θ_0, of the projectile be changed for the range to be halved?

3.32 An air-hockey puck has a model rocket rigidly attached to it. The puck is pushed from one corner along the long side of the 2.00-m-long air-hockey table, with the rocket pointing along the short side of the table, and at the same time the rocket is fired. If the rocket thrust imparts an acceleration of 2.00 m/s^2 to the puck, and the table is 1.00 m wide, with what minimum initial velocity should the puck be pushed to make it to the opposite short side of the table without bouncing off either long side? Draw the trajectory of the puck for three initial velocities: $v < v_{\text{min},} v = v_{\text{min}}$ and $v > v_{\text{min}}$. Neglect friction and air resistance.

3.33 On a battlefield, a cannon fires a cannonball up a slope, from ground level, with an initial velocity v_0 at an angle θ_0 above the horizontal. The ground itself makes an angle α above the horizontal ($\alpha < \theta_0$). What is the range *R* of the cannonball, measured along the inclined ground? Compare your result with the equation for the range on horizontal ground (equation 3.25).

3.34 Two swimmers with a soft spot for physics engage in a peculiar race that models a famous optics experiment: the Michelson-Morley experiment. The race takes place in a river 50.0 m wide that is flowing at a steady rate of 3.00 m/s. Both swimmers start at the same point on one bank and swim at the same speed of 5.00 m/s *with respect to the stream*. One of the swimmers swims directly across the river to the closest point on the opposite bank and then turns around and swims back to the starting point. The other swimmer swims *along* the river bank, first upstream a distance exactly equal to the width of the river and then downstream back to the starting point. Who gets back to the starting point first?

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 3.2

3.35 What is the magnitude of an object's average velocity if the object moves from a point with coordinates $x = 2.0$ m, $y = -3.0$ m to a point with coordinates $x = 5.0$ m, $y = -9.0$ m in a time interval of 2.4 s?

3.36 A man in search of his dog drives first 10.0 mi northeast, then 12.0 mi straight south, and finally 8.0 mi in a direction 30.0° north of west. What are the magnitude and direction of his resultant displacement?

3.37 During a jaunt on your sailboat, you sail 2.00 km east, then 4.00 km southeast, and finally an additional distance in an unknown direction. Your final position is 6.00 km directly east of the starting point. Find the magnitude and direction of the third leg of your journey.

3.38 A truck travels 3.02 km north and then makes a 90.0° left turn and drives another 4.30 km. The whole trip takes 5.00 min.

a) With respect to a two-dimensional coordinate system on the surface of Earth such that the y-axis points north, what is the net displacement vector of the truck for this trip?

b) What is the magnitude of the average velocity for this trip?

·3.39 A rabbit runs in a garden such that the x- and y-components of its displacement as functions of time are given by $x(t) = -0.45t^2 - 6.5t + 25$ and $y(t) = 0.35t^2 + 8.3t + 34$. (Both x and y are in meters and t is in seconds.)

a) Calculate the rabbit's position (magnitude and direction) at $t = 10.0$ s.

b) Calculate the rabbit's velocity at $t = 10.0$ s.

c) Determine the acceleration vector at $t = 10.0$ s.

··3.40 Some rental cars have a GPS unit installed, which allows the rental car company to check where you are at all times and thus also know your speed at any time. One of these rental cars is driven by an employee in the company's lot and, during the time interval from 0 to 10.0 s, is found to have a position vector as a function of time given by

$$\vec{r}(t) = \Big((24.4\text{ m}) - t(12.3\text{ m/s}) + t^2(2.43\text{ m/s}^2), \\ (74.4\text{ m}) + t^2(1.80\text{ m/s}^2) - t^3(0.130\text{ m/s}^3) \Big).$$

a) What is the distance of this car from the origin of the coordinate system at t = 5.00 s?

b) What is the velocity vector as a function of time?

c) What is the speed at t = 5.00 s?

Extra credit: Can you produce a plot of the trajectory of the car in the *xy*-plane?

Section 3.3

3.41 A skier launches off a ski jump with a horizontal velocity of 30.0 m/s (and no vertical velocity component). What are the magnitudes of the horizontal and vertical components of her velocity the instant before she lands 2.00 s later?

3.42 An archer shoots an arrow from a height of 1.14 m above ground with an initial speed of 47.5 m/s and a launch angle of 35.2° above the horizontal. At what time after the release of the arrow from the bow will the arrow be flying exactly horizontally?

3.43 A football is punted with an initial speed of 27.5 m/s and a launch angle of 56.7°. What is its hang time (the time until it hits the ground again)?

3.44 You serve a tennis ball from a height of 1.80 m above the ground. The ball leaves your racket with a speed of 18.0 m/s at an angle of 7.00° above the horizontal. The horizontal distance from the court's baseline to the net is 11.83 m, and the net is 1.07 m high. Neglect any spin imparted on the ball as well as air resistance effects. Does the ball clear the net? If yes, by how much? If not, by how much did it miss?

3.45 Stones are thrown horizontally with the same velocity from two buildings. One stone lands twice as far away from its building as the other stone. Determine the ratio of the heights of the two buildings.

3.46 You are practicing throwing darts in your dorm. You stand 3.00 m from the wall on which the board hangs. The dart leaves your hand with a horizontal velocity at a point 2.00 m above the ground. The dart strikes the board at a point 1.65 m from the ground. Calculate:

a) the time of flight of the dart;

b) the initial speed of the dart;

c) the velocity of the dart when it hits the board.

·**3.47** A football player kicks a ball with a speed of 22.4 m/s at an angle of 49.0° above the horizontal from a distance of 39.0 m from the goalpost.

a) By how much does the ball clear or fall short of clearing the crossbar of the goalpost if that bar is 3.05 m high?

b) What is the vertical velocity of the ball at the time it reaches the goalpost?

·**3.48** An object fired at an angle of 35.0° above the horizontal takes 1.50 s to travel the last 15.0 m of its vertical distance and the last 10.0 m of its horizontal distance. With what speed was the object launched? (Note: The

problem does not specify that the initial and final elevation of the object are the same!)

·**3.49** A conveyor belt is used to move sand from one place to another in a factory. The conveyor is tilted at an angle of 14.0° above the horizontal and the sand is moved without slipping at the rate of 7.00 m/s. The sand is collected in a big drum 3.00 m below the end of the conveyor belt. Determine the horizontal distance between the end of the conveyor belt and the middle of the collecting drum.

·**3.50** Your friend's car is parked on a cliff overlooking the ocean on an incline that makes an angle of 17.0° below the horizontal. The brakes fail, and the car rolls from rest down the incline for a distance of 29.0 m to the edge of the cliff, which is 55.0 m above the ocean, and, unfortunately, continues over the edge and lands in the ocean.

a) Find the car's position relative to the base of the cliff when the car lands in the ocean.

b) Find the length of time the car is in the air.

·**3.51** An object is launched at a speed of 20.0 m/s from the top of a tall tower. The height y of the object as a function of the time t elapsed from launch is $y(t) = -4.90t^2 + 19.32t + 60.0$, where h is in meters and t is in seconds. Determine:

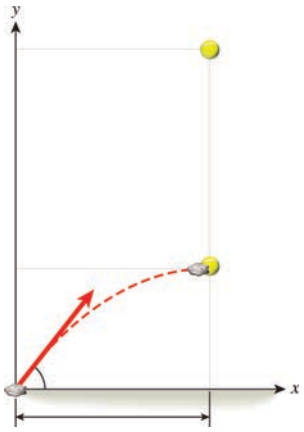
a) the height H of the tower;

b) the launch angle;

c) the horizontal distance traveled by the object before it hits the ground.

·**3.52** A projectile is launched at a 60.0° angle above the horizontal on level ground. The change in its velocity between launch and just before landing is found to be $\Delta\vec{v} = \vec{v}_{\text{landing}} - \vec{v}_{\text{launch}} = -20.0\ \hat{y}\ \text{m/s}$. What is the initial velocity of the projectile? What is its final velocity just before landing?

··**3.53** The figure shows the paths of a tennis ball your friend drops from the window of her apartment and of the rock you throw from the ground at the same instant. The rock and the ball collide at x = 50.0 m, y = 10.0 m and t = 3.00 s. If the ball was dropped from a height of 54.1 m, determine the velocity of the rock initially and at the time of its collision with the ball.



y
x

Section 3.4

3.54 For a science fair competition, a group of high school students build a kicker-machine that can launch a golf ball from the origin with a velocity of 11.2 m/s and a launch angle of 31.5° with respect to the horizontal.

a) Where will the golf ball fall back to the ground?

b) How high will it be at the highest point of its trajectory?

c) What is the ball's velocity vector (in Cartesian components) at the highest point of its trajectory?

d) What is the ball's acceleration vector (in Cartesian components) at the highest point of its trajectory?

3.55 If you want to use a catapult to throw rocks and the maximum range you need these projectiles to have is 0.67 km, what initial speed do the rocks have to have as they leave the catapult?

3.56 What is the maximum height above ground that a projectile of mass 0.790 kg, launched from ground level, can achieve if you are able to give it an initial speed of 80.3 m/s?

·**3.57** During one of the games, you were asked to punt for your football team. You kicked the ball at an angle of 35.0° with a velocity of 25.0 m/s. If your punt goes straight down the field, determine the average speed at which the running back of the opposing team standing at 70.0 m from you must run to catch the ball at the same height as you released it. Assume that the running back starts running as the ball leaves your foot and that the air resistance is negligible.

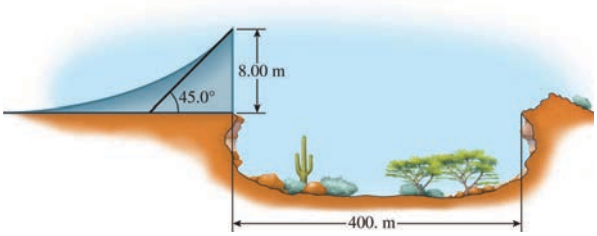
·**3.58** By trial and error, a frog learns that it can leap a maximum horizontal distance of 1.30 m. If, in the course of an hour, the frog spends 20.0% of the time resting and 80.0% of the time performing identical jumps of that maximum length, in a straight line, what is the distance traveled by the frog?

·**3.59** A circus juggler performs an act with balls that she tosses with her right hand and catches with her left hand. Each ball is launched at an angle of 75.0° and reaches a maximum height of 90.0 cm above the launching height. If it takes the juggler 0.200 s to catch a ball with her left hand, pass it to her right hand and toss it back into the air, what is the maximum number of balls she can juggle?

··**3.60** In an arcade game, a ball is launched from the corner of a smooth inclined plane. The inclined plane makes a 30.0° angle with the horizontal and has a width of w = 50.0 cm. The spring-loaded launcher makes an angle of 45.0° with the lower edge of the inclined plane. The

goal is to get the ball into a small hole at the opposite corner of the inclined plane. With what initial speed should you launch the ball to achieve this goal? (*Hint:* If the hole is small, the ball should enter it with zero vertical velocity component.)

••**3.61** A copy cat daredevil tries to reenact Evel Knievel's 1974 attempt to jump the Snake River Canyon in a rocket-powered motorcycle. The canyon is L = 400. m wide, with the opposite rims at the same height. The height of the launch ramp at one rim of the canyon is h = 8.00 m above the rim, and the angle of the end of the ramp is 45.0° with the horizontal.



a) What is the minimum launch speed required for the daredevil to make it across the canyon? Neglect the air resistance and wind.

b) Famous after his successful first jump, but still recovering from the injuries sustained in the crash caused by a strong bounce upon landing, the daredevil decides to jump again but to add a landing ramp with a slope that will match the angle of his velocity at landing. If the height of the landing ramp at the opposite rim is 3.00 m, what is the new required launch speed?

Section 3.5

3.62 A golf ball is hit with an initial angle of 35.5° with respect to the horizontal and an initial velocity of 83.3 mph. It lands a distance of 86.8 m away from where it was hit. By how much did the effects of wind resistance, spin, and so forth reduce the range of the golf ball from the ideal value?

Section 3.6

3.63 You are walking on a moving walkway in an airport. The length of the walkway is 59.1 m. If your velocity relative to the walkway is 2.35 m/s and the walkway moves with a velocity of 1.77 m/s, how long will it take you to reach the other end of the walkway?

3.64 The captain of a boat wants to travel directly across a river that flows due east with a speed of 1.00 m/s. He starts from the south bank of the river and heads toward the north bank. The boat has a speed of 6.10 m/s with respect to the water. In what direction (in degrees) should the captain steer the boat? Note that 90° is east, 180° is south, 270° is west, and 360° is north.

3.65 The captain of a boat wants to travel directly across a river that flows due east. He starts from the south bank of the river and heads toward the north bank. The boat has a speed of 5.57 m/s with respect to the water. The captain steers the boat in the direction 315°. How fast is the water flowing? Note that 90° is east, 180° is south, 270° is west, and 360° is north.

·**3.66** The air-speed indicator of a plane that took off from Detroit reads 350. km/h and the compass indicates that it is heading due east to Boston. A steady wind is blowing due north at 40.0 km/h. Calculate the velocity of the plane with reference to the ground. If the pilot wishes to fly directly to Boston (due east) what must the compass read?

·**3.67** You want to cross a straight section of a river that has a uniform current of 5.33 m/s and is 127. m wide. Your motorboat has an engine that can generate a speed of 17.5 m/s for your boat. Assume that you reach top speed right away (that is, neglect the time it takes to accelerate the boat to top speed).

a) If you want to go directly across the river with a 90.0° angle relative to the riverbank, at what angle relative to the riverbank should you point your boat?

b) How long will it take to cross the river in this way?

c) In which direction should you aim your boat to achieve minimum crossing time?

d) What is the minimum time to cross the river?

e) What is the minimum speed of your boat that will still enable you to cross the river with a 90.0° angle relative to the riverbank?

·**3.68** During a long airport layover, a physicist father and his 8-year-old daughter try a game that involves a moving walkway. They have measured the walkway to be 42.5 m long. The father has a stopwatch and times his daughter. First, the daughter walks with a constant speed in the same direction as the conveyor. It takes 15.2 s to reach the end of the walkway. Then, she turns around and walks with the same speed relative to the conveyor as before, just this time in the opposite direction. The return leg takes 70.8 s. What is the speed of the walkway conveyor relative to the terminal, and with what speed was the girl walking?

·**3.69** An airplane has an air speed of 126.2 m/s and is flying due north, but the wind blows from the northeast to the southwest at 55.5 m/s. What is the plane's actual ground speed?

Additional Exercises

3.70 A cannon is fired from a hill 116.7 m high at an angle of 22.7° with respect to the horizontal. If the muzzle velocity is 36.1 m/s, what is the speed of a 4.35-kg cannonball when it hits the ground 116.7 m below?

3.71 A baseball is thrown with a velocity of 31.1 m/s at an angle of θ= 33.4° above horizontal. What is the horizontal component of the ball's velocity at the highest point of the ball's trajectory?

3.72 A rock is thrown horizontally from the top of a building with an initial speed of v = 10.1 m/s. If it lands d = 57.1 m from the base of the building, how high is the building?

3.73 A car is moving at a constant 19.3 m/s, and rain is falling at 8.90 m/s straight down. What angle θ (in degrees) does the rain make with respect to the horizontal as observed by the driver?

3.74 You tried to pass the salt and pepper shakers to your friend at the other end of a table of height 0.850 m by sliding them across the table. They both slid off the table, with velocities of 5.00 m/s and 2.50 m/s, respectively.

a) Compare the times it takes the shakers to hit the floor.

b) Compare the horizontal distance that each shaker travels from the edge of the table to the point it hits the floor.

3.75 A box containing food supplies for a refugee camp was dropped from a helicopter flying horizontally at a constant elevation of 500. m. If the box hit the ground at a distance of 150. m horizontally from the point of its release, what was the speed of the helicopter? With what speed did the box hit the ground?

3.76 A car is driven straight off the edge of a cliff that is 60.0 m high. The police at the scene of the accident note that the point of impact is 150. m from the base of the cliff. How fast was the car traveling when it went over the cliff?

3.77 At the end of the spring term, a high school physics class celebrates by shooting a bundle of exam papers into the town landfill with a homemade catapult. They aim for a point that is 30.0 m away and at the same height from which the catapult releases the bundle. The initial horizontal velocity component is 3.90 m/s. What is the initial velocity component in the vertical direction? What is the launch angle?

3.78 Salmon often jump upstream through waterfalls to reach their breeding grounds. One salmon came across a waterfall 1.05 m in height,

which she jumped in 2.10 s at an angle of 35.0° above the horizontal to continue upstream. What was the initial speed of her jump?

3.79 A firefighter, 60.0 m away from a burning building, directs a stream of water from a ground-level fire hose at an angle of 37.0° above the horizontal. If the water leaves the hose at 40.3 m/s, which floor of the building will the stream of water strike? Each floor is 4.00 m high.

3.80 A projectile leaves ground level at an angle of 68.0° above the horizontal. As it reaches its maximum height, H, it has traveled a horizontal distance, d, in the same amount of time. What is the ratio H/d?

3.81 The McNamara Delta terminal at the Metro Detroit Airport has moving walkways for the convenience of the passengers. Robert walks beside one walkway and takes 30.0 s to cover its length. John simply stands on the walkway and covers the same distance in 13.0 s. Kathy walks on the walkway with the same speed as Robert's. How long does Kathy take to complete her stroll?

3.82 Rain is falling vertically at a constant speed of 7.00 m/s. At what angle from the vertical do the raindrops appear to be falling to the driver of a car traveling on a straight road with a speed of 60.0 km/h?

3.83 To determine the gravitational acceleration at the surface of a newly discovered planet, scientists perform a projectile motion experiment. They launch a small model rocket at an initial speed of 50.0 m/s and an angle of 30.0° above the horizontal and measure the (horizontal) range on flat ground to be 2165 m. Determine the value of g for the planet.

3.84 A diver jumps from a 40.0-m-high cliff into the sea. Rocks stick out of the water for a horizontal distance of 7.00 m from the foot of the cliff. With what minimum horizontal speed must the diver jump off the cliff in order to clear the rocks and land safely in the sea?

3.85 An outfielder throws a baseball with an initial speed of 32.0 m/s at an angle of 23.0° to the horizontal. The ball leaves his hand from a height of 1.83 m. How long is the ball in the air before it hits the ground?

·**3.86** A rock is tossed off the top of a cliff of height 34.9 m. Its initial speed is 29.3 m/s, and the launch angle is 29.9° above the horizontal. What is the speed with which the rock hits the ground at the bottom of the cliff?

·**3.87** During the 2004 Olympic Games, a shot putter threw a shot put with a speed of 13.0 m/s at an angle of 43.0° above the horizontal. She released the shot put from a height of 2.00 m above the ground.

a) How far did the shot put travel in the horizontal direction?

b) How long was it until the shot put hit the ground?

·**3.88** A salesman is standing on the Golden Gate Bridge in a traffic jam. He is at a height of 71.8 m above the water below. He receives a call on his cell phone that makes him so mad that he throws his phone horizontally off the bridge with a speed of 23.7 m/s.

a) How far does the cell phone travel horizontally before hitting the water?

b) What is the speed with which the phone hits the water?

·**3.89** A security guard is chasing a burglar across a rooftop, both running at 4.20 m/s. Before the burglar reaches the edge of the roof, he has to decide whether or not to try jumping to the roof of the next building, which is 5.50 m away and 4.00 m lower. If he decides to jump horizontally to get away from the guard, can he make it? Explain your answer.

·**3.90** A blimp is ascending at the rate of 7.50 m/s at a height of 80.0 m above the ground when a package is thrown from its cockpit horizontally with a speed of 4.70 m/s.

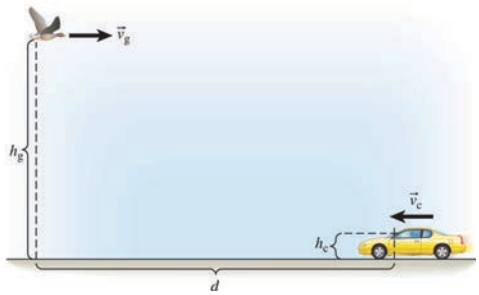
a) How long does it take for the package to reach the ground?

b) With what velocity (magnitude and direction) does it hit the ground?

·**3.91** Wild geese are known for their lack of manners. One goose is flying northward at a level altitude of $h_g = 30.0$ m above a north-south highway, when it sees a car ahead in the distance moving in the southbound lane and decides to deliver (drop) an "egg." The goose is flying at a speed of $v_g = 15.0$ m/s, and the car is moving at a speed of $v_c = 100.0$ km/h.

a) Given the details in the figure, where the separation between the goose and the car's windshield, d = 104.0 m, is specified at the instant when the goose takes action, will the driver have to wash the windshield after this encounter? (The center of the windshield is $h_c = 1.00$ m off the ground.)

b) If the delivery is completed, what is the relative velocity of the "egg" with respect to the car at the moment of the impact?



·**3.92** You are at the mall on the top step of a down escalator when you lean over laterally to see your 1.80-m-tall physics professor on the bottom step of the adjacent up escalator. Unfortunately, the ice cream you hold in your hand falls out of its cone as you lean. The two escalators have identical angles of 40.0° with the horizontal, a vertical height of 10.0 m, and move at the same speed of 0.400 m/s. Will the ice cream land on your professor's head? Explain. If it does land on his head, at what time and at what vertical height does that happen? What is the relative speed of the ice cream with respect to the head at the time of impact?

·**3.93** A basketball player practices shooting three-pointers from a distance of 7.50 m from the hoop, releasing the ball at a height of 2.00 m above the floor. A standard basketball hoop's rim top is 3.05 m above the floor. The player shoots the ball at an angle of 48.0° with the horizontal. At what initial speed must she shoot to make the basket?

·**3.94** Wanting to invite Juliet to his party, Romeo is throwing pebbles at her window with a launch angle of 37.0° from the horizontal. He is launching the pebble 7.00 m below her window and 10.0 m from the base of the wall. What is the initial speed of the pebbles?

·**3.95** An airplane flies horizontally above the flat surface of a desert at an altitude of 5.00 km and a speed of 1000. km/h. If the airplane is to drop a bomb that is supposed to hit a target on the ground, where should the plane be with respect to the target when the bomb is released? If the target covers a circular area with a diameter of 50.0 m, what is the "window of opportunity" (or margin of error allowed) for the release time?

·**3.96** A plane diving with constant speed, at an angle of 49.0° with the vertical, releases a package at an altitude of 600. m. The package hits the ground 3.50 s after release. How far horizontally does the package travel?

··**3.97** At a time of 10.0 s after being fired, a cannonball strikes a point 500. m horizontally from and 100. m vertically above the point of launch.

a) With what initial velocity was the cannonball launched?

b) What maximum height was attained by the ball?

c) What is the magnitude and direction of the ball's velocity just before it strikes the given point?

••**3.98** Neglect air resistance for the following. A soccer ball is kicked from the ground into the air. When the ball is at a height of 12.5 m, its velocity is $\left(5.60\hat{x} + 4.10\hat{y}\right)$ m/s.

a) To what maximum height will the ball rise?

b) What horizontal distance will be traveled by the ball?

c) With what velocity (magnitude and direction) will it hit the ground?

MULTI-VERSION EXERCISES

3.99 For a Science Olympiad competition, a group of middle school students build a trebuchet that can fire a tennis ball from a height of 1.55 m with a velocity of 10.5 m/s and a launch angle of 35.0° above the horizontal. What horizontal distance will the tennis ball cover before it hits the ground?

3.100 For a Science Olympiad competition, a group of middle school students build a trebuchet that can fire a tennis ball from a height of 1.55 m with a velocity of 10.5 m/s and a launch angle of 35.0° above the horizontal. What is the x-component of the velocity of the tennis ball just before it hits the ground?

3.101 For a Science Olympiad competition, a group of middle school students build a trebuchet that can fire a tennis ball from a height of 1.55 m with a velocity of 10.5 m/s and a launch angle of 35.0° above the horizontal. What is the y-component of the velocity of the tennis ball just before it hits the ground?

3.102 For a Science Olympiad competition, a group of middle school students build a trebuchet that can fire a tennis ball from a height of 1.55 m with a velocity of 10.5 m/s and a launch angle of 35.0° above the horizontal. What is the speed of the tennis ball just before it hits the ground?

3.103 A pilot flies her airplane from its initial position to a position 200.0 km north of that spot. The airplane flies with a speed of 250.0 km/h with respect to the air. The wind is blowing west to east with a speed of 45.0 km/h. In what direction should the pilot steer her plane to accomplish this trip? (Express your answer in degrees, noting that east is 90°, south is 180°, west is 270°, and north is 360°.)

3.104 A pilot flies her airplane from its initial position to a position 200.0 km north of that spot. The airplane flies with a speed of 250.0 km/h with respect to the air. The wind is blowing west to east with a speed of 45.0 km/h. What is the speed of the plane with respect to the ground?

3.105 A pilot flies her airplane from its initial position to a position 200.0 km north of that spot. The airplane flies with a speed of 250.0 km/h with

respect to the air. The wind is blowing west to east with a speed of 45.0 km/h. How long will it take to make the trip?

FIGURE 4.1 The Space Shuttle *Columbia* lifts off from the Kennedy Space Center.

NASA

The launch of a space shuttle was an awesome sight, as captured in Figure 4.1. Huge clouds of smoke obscured the shuttle until it rose up high enough to be seen above them, with brilliant exhaust flames exiting the main engines. The boosters provided a force of over 30 meganewtons, enough to shake the ground for miles around. This tremendous force accelerated the shuttle (whose mass was over 2 million kilograms) sufficiently for lift off.

The space shuttle has been called one of the greatest technological achievements of the 20th century, but the basic principles of force, mass, and acceleration that govern its operation have been known for over 300 years. First stated by Isaac Newton in 1687, the laws of motion apply to all interactions between objects. Just as kinematics

describes how objects move, Newton's laws of motion are the foundation of **dynamics**, which describes what makes objects move. We will study dynamics for the next several chapters.

In this chapter, we examine Newton's laws of motion and explore the various kinds of forces they describe. The process of identifying the forces that act on an object, determining the motion caused by those forces, and interpreting the overall vector result is one of the most common and important types of analysis in physics, and we will use it numerous times throughout this book. Many of the kinds of forces introduced in this chapter, such as contact forces, friction forces, and weight, will play a role in many of the concepts and principles discussed later.

WHAT WE WILL LEARN

- A force is a vector quantity that is a measure of how an object interacts with other objects.
- Fundamental forces include gravitational attraction and electromagnetic attraction and repulsion. In daily experience, important forces include tension and normal, friction, and spring forces.
- Multiple forces acting on an object sum to a net force.
- Free-body diagrams are valuable aids in working problems.
- Newton's three laws of motion govern the motion of objects under the influence of forces.
  a) The first law deals with objects for which external forces are balanced.
  b) The second law describes those cases for which external forces are not balanced.
  c) The third law addresses equal (in magnitude) and opposite (in direction) forces that two bodies exert on each other.
- The gravitational mass and the inertial mass of an object are equivalent.
- Kinetic friction opposes the motion of moving objects; static friction opposes the impending motion of objects at rest.
- Friction is important to the understanding of real-world motion, but its causes and exact mechanisms are still under investigation.
- Newton's laws of motion apply to situations involving multiple objects, multiple forces, and friction; applying the laws to analyze a situation is among the most important problem-solving techniques in physics.

4.1 Types of Forces

You are probably sitting on a chair as you are reading this page. The chair exerts a force on you, which prevents you from falling to the ground. You can feel this force from the chair on the underside of your legs and your backside. Conversely, you exert a force on the chair.

If you pull on a string, you exert a force on the string, and that string, in turn, can exert a force on something tied to its other end. This force, as well as the force you exert on a chair you're sitting in, is an example of a **contact force**, in which one object has to be in contact with another to exert a force on it. If you push or pull on an object, you exert a contact force on it. Pulling on an object, such as a rope or a string, gives rise to the contact force called **tension**. Pushing on an object causes the contact force called **compression**. The force that acts on you when you sit on a chair is called a **normal force**, where the word *normal* means "perpendicular to the surface." We will examine normal forces in more detail a little later in this chapter.

The **friction force** is another important contact force that we will study in more detail in this chapter. If you push a glass across the surface of a table, it comes to rest rather quickly. The force that causes the glass's motion to stop is the friction force, sometimes also simply called *friction*. Interestingly, the exact nature and microscopic origin of the friction force are still under intense investigation, as we'll see.

A force is needed to compress a spring as well as to extend it. The **spring force** has the special property of being linearly dependent on the change in length of the spring. Chapter 5 will introduce the spring force and describe some of its properties. Chapter 14 will focus on oscillations, a special kind of motion resulting from the action of spring forces.

Contact forces, friction forces, and spring forces are the results of the **fundamental forces** of nature acting between the constituents of objects. The **gravitational force**, often simply called *gravity,* is one example of a fundamental force. If you hold an object in your hand and let go of it, it falls downward. We know what causes this effect: the gravitational attraction between the Earth and the object.

Gravitational acceleration was introduced in Chapter 2, and this chapter describes how it is related to the gravitational force. Gravity is also responsible for holding the Moon in orbit around the Earth and the Earth in orbit around the Sun. In a famous story (which may even be true!), Isaac Newton was reported to have had this insight in the 17th century, after sitting under an apple tree and being hit by an apple falling off the tree: The same type of gravitational force acts between celestial objects as operates between terrestrial objects. However, keep in mind that the gravitational force discussed in this chapter is a limited instance, valid only near the surface of Earth, of the more general gravitational force. Near the surface of Earth, a constant gravitational force acts on all objects, which is sufficient to solve practically all trajectory problems of the kind covered in Chapter 3. The more general form of the gravitational interaction, however, is inversely proportional to the square of the distance between the two objects exerting the gravitational force on each other. Chapter 12 is devoted to this force.

Another fundamental force that can act at a distance is the **electromagnetic force**, which, like the gravitational force, is inversely proportional to the square of the distance over which it acts. The most apparent manifestation of this force is the attraction or repulsion between two magnets, depending on their relative orientation. The entire Earth also acts as a huge magnet, which makes compass needles orient themselves toward the North Pole. The electromagnetic force was the big physics discovery of the 19th century, and its refinement during the 20th century led to many of the high-tech conveniences (basically everything that plugs into an electrical outlet or uses batteries) we enjoy today. Chapters 21 through 31 will provide an extensive tour of the electromagnetic force and its many manifestations.

In particular, we will see that all of the contact forces listed above (normal force, tension, friction, spring force) are fundamentally consequences of the electromagnetic force. Why then study these contact forces in the first place? The answer is that phrasing a problem in terms of contact forces gives us great insight and allows us to formulate simple solutions to real-world problems whose

solutions would otherwise require the use of supercomputers if we tried to analyze them in terms of the electromagnetic interactions between atoms.

The other two fundamental forces—called the **strong nuclear force** and the **weak nuclear force**—act only on the length scales of atomic nuclei and between elementary particles. These forces between elementary particles will be discussed in Chapter 39 on particle physics and Chapter 40 on nuclear physics. In general, forces can be defined as the means for objects to influence each other (Figure 4.2).

(a)

(b)

(c)

FIGURE 4.2 Some common types of forces. (a) A grinding wheel works by using the force of friction to remove the outer surface of an object. (b) Springs are often used as shock absorbers in cars to reduce the force transmitted to the wheels by the ground. (c) Some dams are among the largest structures

ever built. They are designed to resist the force exerted by the water they hold back.

a: Dex Image/CORBIS; **b:** Richard McDowell/Alamy Stock Photo; **c:** photo by Lynn Betts, USDA Natural Resources Conservation Service

Most of the forces mentioned here have been known for hundreds of years. However, the ways in which scientists and engineers use forces continue to evolve as new materials and new designs are created. For example, the idea of a bridge to cross a river or deep ravine has been used for thousands of years, starting with simple forms such as a log dropped across a stream or a series of ropes strung across a gorge. Over time, engineers developed the idea of an arch bridge that can support a heavy roadway and a load of traffic using compressive forces. Many such bridges were built from stone or steel, materials that can support compression well (Figure 4.3a). In the late 19th and 20th centuries, bridges were built with the roadway suspended from steel cables supported by tall piers (Figure 4.3b). The cables supported tension, and these bridges could be lighter as well as longer than previous bridge designs. In the late 20th century, cable-stayed bridges began to appear, with the roadway supported by cables attached directly to the piers (Figure 4.3c). These bridges are not generally as long as suspension bridges but are less expensive and time-consuming to build.

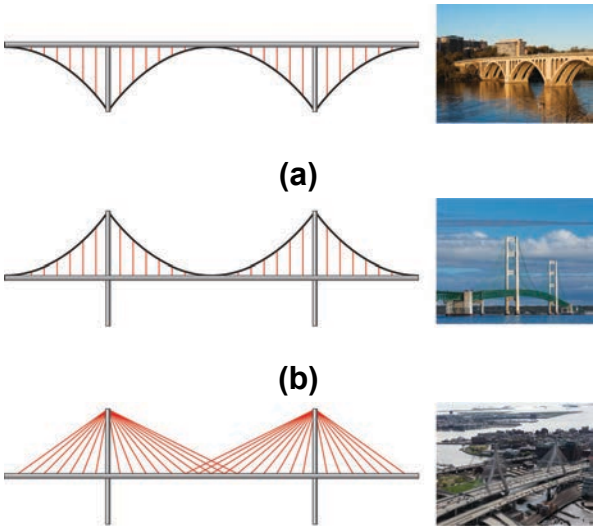

FIGURE 4.3 Different ways to use forces. (a) Arch bridges (such as Francis Scott Key Bridge in Washington, DC) support a road by compressive forces, with each end of the arch anchored in place. (b) Suspension bridges (such as Mackinac Bridge in Michigan) support the roadway by tension forces in the cables, which are in turn supported by compressive forces in the tall piers sunk into the ground below the water. (c) Cable-stayed bridges (such as Zakim Bridge in Boston) also use tension forces in cables to support the roadway, but the load is distributed over many more cables, which do not need to be as strong as in suspension bridges.

4.2 Gravitational Force Vector, Weight, and Mass

Having had a general introduction to forces, it is time to get more quantitative. Let's start with an obvious fact: Forces have a direction. For example, if you are holding a laptop computer in your hand, you can easily tell that the gravitational force acting on the computer points downward. This direction is the direction of the **gravitational force vector** (Figure 4.4). Again, to characterize a quantity as a vector quantity throughout this book, a small right-pointing arrow appears above the symbol for the quantity. Thus, the gravitational force vector acting on the laptop is denoted by $\overrightarrow{F}_{\text{g}}$ in the figure.

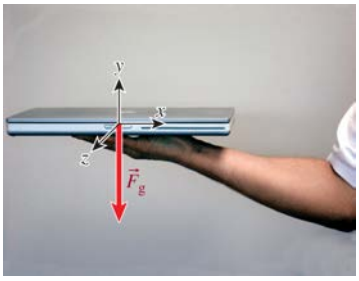

FIGURE 4.4 Force vector of gravity acting on a laptop computer, in relation to the conventional right-handed Cartesian coordinate system.

W. Bauer and G. D. Westfall

Figure 4.4 also shows a convenient Cartesian coordinate system, which follows the convention introduced in Chapter 3 but has been rotated so that up is the positive y-direction (and down the negative y-direction). The x- and z-directions then lie in the horizontal plane,

as shown. As always, we use a right-handed coordinate system. Also, we restrict ourselves to two-dimensional coordinate systems with x- and y-axes wherever possible.

In the coordinate system in Figure 4.4, the force vector of the gravitational force acting on the laptop is pointing in the negative y-direction:

$$\overrightarrow{F}_{\mathrm{g}} = -F_{\mathrm{g}}\hat{y}. \tag{4.1}$$

Here we see that the force vector is the product of its magnitude, F_{g}, and its direction, $-\hat{y}$. The magnitude F_{g} is called the **weight** of the object.

Near the surface of the Earth (within a few hundred meters above the ground), the magnitude of the gravitational force acting on an object is given by the product of the mass of the object, m, and the Earth's gravitational acceleration, g:

$$F_{\mathrm{g}} = mg. \tag{4.2}$$

We have used the magnitude of the Earth's gravitational acceleration in previous chapters: It has the value g = 9.81 m/s^2. Note that this constant value is valid only up to a few hundred meters above the ground, as we will see in Chapter 12.

With equation 4.2, we find that the unit of force is the product of the unit of mass (kg) and the unit of acceleration (m/s^2), which makes the unit of force kg m/s^2. (Perhaps it is worth repeating that we represent units with roman letters and physical quantities with italic letters. Thus, m is the unit of length; m stands for the physical quantity of mass.) Since dealing with forces is so common in physics, the unit of force has received its own name, the newton (N), after Sir Isaac Newton, the British physicist who made a key contribution to the analysis of forces.

$$1\ \mathrm{N} \equiv 1\ \mathrm{kg\ m/s^2}. \tag{4.3}$$

Weight versus Mass

Before discussing forces in greater detail, we need to clarify the concept of mass. Under the influence of gravity, an object has a weight that is proportional to its **mass**, which is (intuitively) the amount of matter in the object. This weight is the magnitude of a force that acts on an object due to its gravitational interaction with the Earth (or another object). Near the surface of Earth, the magnitude of this force is $F_{\mathrm{g}} = mg$, as stated in equation 4.2. The mass in this equation is also called the **gravitational mass** to indicate that it is responsible for the gravitational interaction. However, mass has a role in dynamics as well.

Newton's laws of motion, which will be introduced later in this chapter, deal with inertial mass. To understand the concept of inertial mass, consider the following examples: It is a lot easier to throw a tennis ball than a shot put. It is also easier to pull open a door made of lightweight materials like foam-core with wood veneer than one made of a heavy material like iron. The more massive objects seem to resist being put into motion more than the less massive ones do. This property of an object is referred to as its **inertial mass**. However, the gravitational mass and the inertial mass are identical, so most of the time we refer simply to the mass of an object.

Concept Check 4.1

Consider two steel balls. Ball 1 has a weight of 1.5 N. Ball 2 has a weight of 15 N. Both balls are released simultaneously from a height of 2.0 m. Which ball hits the ground first?

a) Ball 1 hits the ground first.

b) Ball 2 hits the ground first.

c) Both balls hit the ground at the same time.

d) It can't be determined from the information provided.

For a laptop computer with mass m = 3.00 kg, for example, the magnitude of the gravitational force is $F_g = mg = (3.00\ \text{kg})\left(9.81\ \text{m/s}^2\right) = 29.4\ \text{kg}\ \text{m/s}^2 = 29.4\ \text{N}$. Now we can write an equation for the force vector that contains both the magnitude and the direction of the gravitational force acting on the laptop computer (see Figure 4.4):

$$\vec{F}_g = -mg\hat{y}. \tag{4.4}$$

To summarize, the mass of an object is measured in kilograms and the weight of an object is measured in newtons. The mass and the weight of an object are related to each other by multiplying the mass (in kilograms) by the gravitational acceleration constant, g = 9.81 m/s^2, to arrive at the weight (in newtons). For example, if your mass is 70.0 kg, then your weight is 687 N.

Orders of Magnitude of Forces

The concept of a force is a central theme of this book, and we will return to it again and again. For this reason, it is instructive to look at the orders of magnitude that different forces can have. Figure 4.5 gives an overview of magnitudes of some typical forces with the aid of a logarithmic scale, similar to those used in Chapter 1 for length and mass.

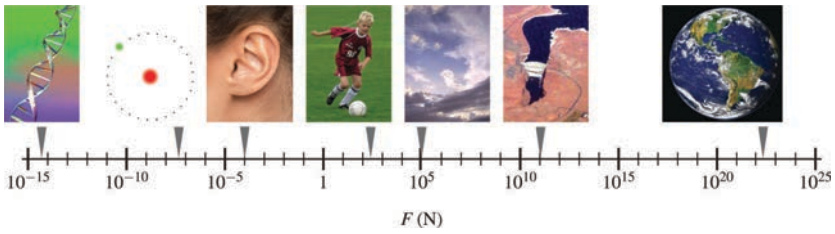

FIGURE 4.5 Typical magnitudes for different forces.

(DNA helix): Radius Images/Alamy Stock Photo; **(Ear):** Blackday/Shutterstock; **(Boy playing soccer):** W. Bauer and G. D. Westfall; **(Sunlight through Clouds):** Photo 24/Getty Images; **(Aerial view of dam):** W. Bauer and G. D. Westfall; **(Earth):** Reto Stöckli, Nazmi El Saleous, and Marit Jentoft-Nilsen, NASA

A human's body weight is in the range between 100 and 1000 N and is represented by the young soccer player in Figure 4.5. The ear to the player's left in Figure 4.5 symbolizes the force exerted by sound on our eardrums, which can be as large as 10^{-4}N, but is still detectable when it is as small as 10^{-13}N. (Chapter 16 will focus on sound.) A single electron is kept in orbit around a proton by an electrostatic force of approximately 10^{-7}N, which will be introduced in Chapter 21 on electrostatics. Forces as small as $10^{-15}\text{N} \equiv 1$ fN can be measured in the lab; these forces are typical of those needed to stretch the double-helical DNA molecule.

The Earth's atmosphere exerts quite a sizable force on our bodies, on the order of 10^{5}N, which is approximately 100 times the average body weight. Chapter 13 on solids and fluids will expand on this topic and will also show how to calculate the force of water on a dam. For example, the Hoover Dam (shown in Figure 4.5) has to withstand a force close to 10^{11}N, a huge force, more than 30 times the weight of

the Empire State Building. But this force pales, of course, in comparison to the gravitational force that the Sun exerts on Earth, which is $3.5 \cdot 10^{22}$N. (Chapter 12 on gravity will describe how to calculate this force.)

Higgs Particle

As far as our studies are concerned, mass is an intrinsic, or given, property of an object. The origin of mass is still under intense study in nuclear and particle physics. Different elementary particles have been observed to vary widely in mass—in fact, some are several thousand times more massive than others. Why? We don't really know. In recent years, particle physicists have theorized that the so-called **Higgs particle** (named after Scottish physicist Peter Higgs, who first proposed it) may be responsible for imparting mass to all other particles, with the mass of a particular type of particle depending on how it interacts with the Higgs particle. On July 4, 2012, the ATLAS and CMS Collaborations at the Large Hadron Collider at CERN in Geneva, Switzerland, announced the discovery of the Higgs particle, which was the last undiscovered particle predicted by the standard model of particle physics.

4.3 Net Force

Because forces are vectors, we must add them as vectors, using the methods developed in Chapter 1. We define the **net force** as the vector sum of all force vectors that act on an object:

$$\vec{F}_{\text{net}} = \sum_{i=1}^{n} \vec{F}_i = \vec{F}_1 + \vec{F}_2 + \cdots + \vec{F}_n. \qquad \textbf{(4.5)}$$

Following the rules for the addition of vectors using components, we can write the Cartesian components of the net force:

$$\begin{aligned} F_{\text{net},x} &= \sum_{i=1}^{n} F_{i,x} = F_{1,x} + F_{2,x} + \cdots + F_{n,x} \\ F_{\text{net},y} &= \sum_{i=1}^{n} F_{i,y} = F_{1,y} + F_{2,y} + \cdots + F_{n,y} \\ F_{\text{net},z} &= \sum_{i=1}^{n} F_{i,z} = F_{1,z} + F_{2,z} + \cdots + F_{n,z}. \end{aligned} \qquad \textbf{(4.6)}$$

To explore the concept of the net force, let's return again to the example of the laptop held up by a hand.

Normal Force

So far we have only looked at the gravitational force acting on the laptop computer. However, other forces are also acting on it. What are they?

In Figure 4.6, the force exerted on the laptop computer by the hand is represented by the yellow arrow labeled $\vec{N}$. (Careful—the magnitude of the normal force is represented by the italic letter *N*, whereas the force unit, the newton, is represented by the roman letter N.) Note in the figure that the magnitude of the vector $\vec{N}$ is exactly equal to that of the vector $\vec{F}_{\text{g}}$ and that the two vectors point in opposite directions, or $\vec{N} = -\vec{F}_{\text{g}}$. This situation is not an accident. We will see shortly that there is no net force on an object at rest. If we calculate the net force acting on the laptop computer, we obtain

$$\vec{F}_{\text{net}} = \sum_{i=1}^{n} \vec{F}_i = \vec{F}_{\text{g}} + \vec{N} = \vec{F}_{\text{g}} - \vec{F}_{\text{g}} = 0.$$

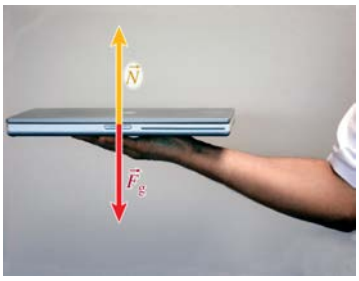

FIGURE 4.6 Force of gravity acting downward and normal force acting upward exerted by the hand holding the laptop computer.

W. Bauer and G. D. Westfall

In general, we can characterize the *normal force,* $\vec{N}$, as a contact force that acts at the surface between two objects. The normal force is always directed perpendicular to the plane of the contact surface. (Hence the name—*normal* means "perpendicular.") The normal force is just large enough that the objects do not penetrate each other and is not necessarily equal to the force of gravity in all situations.

For the hand holding the laptop computer, the contact surface between the hand and the computer is the bottom surface of the computer, which is aligned with the horizontal plane. By definition, the normal force has to point perpendicular to this plane, or vertically upward in this case.

Free-body diagrams greatly ease the task of determining net forces on objects.

Free-Body Diagrams

We have represented the entire effect that the hand has in holding up the laptop computer by the force vector $\vec{N}$. We do not need to consider the influence of the arm, the person to whom the arm belongs, or the entire rest of the world when we want to consider the forces acting on the laptop computer. We can just eliminate them from our consideration, as illustrated in Figure 4.7a, where everything but the laptop computer and the two force vectors has been removed. For that matter, a realistic representation of the laptop computer is not necessary either; it can be shown as a dot, as in Figure 4.7b. This type of drawing of an object, in which all connections to the rest of the world are ignored and only the force vectors that act on it are drawn, is called a **free-body diagram**.

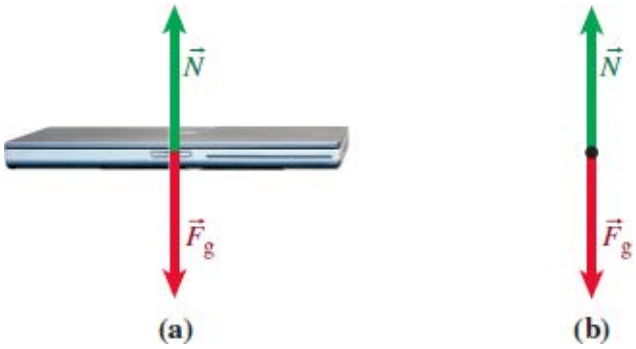

FIGURE 4.7 (a) Forces acting on a real object, a laptop computer; (b) abstraction of the object as a free body being acted on by two forces.

4.4 Newton's Laws

So far this chapter has introduced several types of forces without really explaining how they work and how we can deal with them. The key to working with forces involves understanding Newton's laws. We discuss these laws in this section and then present several examples showing how they apply to practical situations.

Sir Isaac Newton (1642–1727) was perhaps the most influential scientist who ever lived. He is generally credited with being the founder of modern mechanics, as well as calculus (along with the German mathematician Gottfried Leibniz). The first few chapters of this book are basically about Newtonian mechanics. Although he formulated his three famous laws in the 17th century, these laws are still the foundation of our understanding of forces. To begin this discussion, we simply list Newton's three laws, published in 1687.

Newton's First Law:

If the net force on an object is equal to zero, the object will remain at rest if it was at rest. If it was moving, it will remain in motion in a straight line with the same constant velocity.

Newton's Second Law:

If a net external force, $\vec{F}_{\text{net}}$, acts on an object with mass m, the force will cause an acceleration, $\vec{a}$, in the same direction as the force:

$$\vec{F}_{\text{net}} = m\vec{a}.$$

Newton's Third Law:

The forces that two interacting objects exert on each other are always exactly equal in magnitude and opposite in direction:

$$\vec{F}_{1\to 2} = -\vec{F}_{2\to 1}.$$

Newton’s First Law

The earlier discussion of net force mentioned that zero net external force is the necessary condition for an object to be at rest. We can use this condition to find the magnitude and direction of any unknown forces in a problem. That is, if we know that an object is at rest and we know its weight force, then we can use the condition $\overrightarrow{F}_{\text{net}} = 0$ to solve for other forces acting on the object. This kind of analysis led to the magnitude and direction of the force $\overrightarrow{N}$ in the example of the laptop computer being held at rest.

We can use this way of thinking as a general principle: If object 1 rests on object 2, then the normal force $\overrightarrow{N}$ equal to the object’s weight keeps object 1 at rest, and therefore the net force on object 1 is zero. If $\overrightarrow{N}$ were larger than the object’s weight, object 1 would lift off into the air. If $\overrightarrow{N}$ were smaller than the object’s weight, object 1 would sink into object 2.

Newton’s First Law says there are two possible states for an object with no net force on it: An object at rest is said to be in **static equilibrium**. An object moving with constant velocity is said to be in **dynamic equilibrium**.

Before we move on, it is important to state that the equation $\overrightarrow{F}_{\text{net}} = 0$ as a condition for static equilibrium really represents one equation for each dimension of the coordinate space that we are considering. Thus, in three-dimensional space, we have three independent equilibrium conditions:

$$F_{\text{net},x} = \sum_{i=1}^{n} F_{i,x} = F_{1,x} + F_{2,x} + \cdots + F_{n,x} = 0$$

$$F_{\text{net},y} = \sum_{i=1}^{n} F_{i,y} = F_{1,y} + F_{2,y} + \cdots + F_{n,y} = 0$$

$$F_{\text{net},z} = \sum_{i=1}^{n} F_{i,z} = F_{1,z} + F_{2,z} + \cdots + F_{n,z} = 0.$$

However, Newton's First Law also addresses the case when an object is already in motion with respect to some particular reference frame. For this case, the law specifies that the acceleration is zero, provided the net external force is zero. Newton's abstraction claims something that seemed at the time in conflict with everyday experience. Today, however, we have the benefit of having seen videos or movies showing objects floating in a spaceship, moving with unchanged velocities until an astronaut pushes them and thus exerts a force on them. This visual experience is in complete accord with what Newton's First Law claims, but no one in Newton's time had seen it.

Consider a car that is out of gas and needs to be pushed to the nearest gas station on a horizontal street. As long as you push the car, you can make it move. However, as soon as you stop pushing, the car slows down and comes to a stop. It seems that as long as you push the car, it moves at constant velocity, but as soon as you stop exerting a force on it, it stops moving. This idea that a constant force is required to move something with a constant speed was the Aristotelian view, which originated from the ancient Greek philosopher Aristotle (384–322 BC) and his students. Galileo (1564–1642) proposed a law of inertia and theorized that moving objects slowed down because of friction. Newton's First Law builds on this law of inertia.

What about the car that slows down once you stop pushing? This situation is not a case of zero net force. Instead, a force *is* acting on the car to slow it down—the force of friction. Because the friction force acts as a nonzero net force, the example of the car slowing down turns out to be an example not of Newton's First Law, but of Newton's Second Law. We will work more with friction later in this chapter.

Newton's First Law is sometimes also called the *law of inertia*. Inertial mass was defined earlier (Section 4.2), and the definition implied that inertia is an object's resistance to a change in its motion. This is exactly what Newton's First Law says: To change an object's motion, you need to apply an external net force—the motion won't change by itself, neither in magnitude nor in direction.

Newton's Second Law

The second law relates the concept of acceleration, for which we use the symbol $\overrightarrow{a}$, to the force. We have already considered acceleration as the time derivative of the velocity and the second time derivative of the position. Newton's Second Law tells us what causes acceleration.

Newton's Second Law:

If a net external force, $\overrightarrow{F}_{\text{net}}$, acts on an object with mass m, the force will cause an acceleration, $\overrightarrow{a}$, in the same direction as the force:

$$\overrightarrow{F}_{\text{net}} = m\overrightarrow{a}. \qquad \textbf{(4.7)}$$

This formula, $F = ma$, is arguably the second-most famous equation in all of physics. (We will encounter the most famous, $E = mc^2$, later in the book.) Equation 4.7 tells us that the magnitude of the acceleration of an object is proportional to the magnitude of the net external force acting on it. It also tells us that for a given external force, the magnitude of the acceleration is inversely proportional to the mass of the object. All things being equal, more massive objects are harder to accelerate than less massive ones.

However, equation 4.7 tells us even more, because it is a vector equation. It says that the acceleration vector experienced by the object with mass m is in the same direction as the net external force vector that is acting on the object to cause this acceleration. Because it is a vector equation, we can immediately write the equations for the three spatial components:

$$F_{\text{net},x} = ma_x, \;\; F_{\text{net},y} = ma_y, \;\; F_{\text{net},z} = ma_z.$$

This result means that $F = ma$ holds independently for each Cartesian component of the force and acceleration vectors.

Concept Check 4.2

The second-most famous equation in physics is

a) $E = mc^2$.

b) $F = ma$.

c) $pV = nRT$.

d) $p = mv$.

e) $K = (1/2)mv^2$.

Newton’s Third Law

If you have ever ridden a skateboard, you must have made the following observation: If you are standing at rest on the skateboard, and you step off over the front or back, the skateboard shoots off into the opposite direction. In the process of stepping off, the skateboard exerts a force on your foot, and your foot exerts a force onto the skateboard. This experience seems to suggest that these forces point in opposite directions, and it provides one example of a general truth, quantified in Newton’s Third Law.

Newton’s Third Law:

The forces that two interacting objects exert on each other are always exactly equal in magnitude and opposite in direction:

$$\overrightarrow{F}_{1\to 2} = -\overrightarrow{F}_{2\to 1}. \tag{4.8}$$

Note that these two forces do not act on the same body but are the forces with which two bodies act on each other.

Newton’s Third Law seems to present a paradox. For example, if a horse pulls forward on a wagon with the same force with which the wagon pulls backward on the horse, then how do horse and wagon move anywhere? The answer is that these forces act on different objects in the system. The wagon experiences the pull from the horse and moves forward. The horse feels the pull from the wagon and pushes hard enough against the ground to overcome this force and move forward. A free-body diagram of an object can show only half of such an action-reaction pair of forces.

Newton’s Third Law is a consequence of the requirement that internal forces—that is, forces that act between different components of the same system—must add to zero; otherwise, their sum would contribute to a net external force and cause an acceleration, according to Newton’s Second Law. No object or group of objects can accelerate itself or themselves without interacting with external objects. The story of Baron Münchhausen, who claimed to have pulled himself out of a swamp by simply pulling very hard on his own hair, is unmasked by Newton’s Third Law as complete fiction.

We'll consider some examples of the use of Newton's laws to solve problems, after we discuss how ropes and pulleys convey forces. Many problems involving Newton's laws involve forces on a rope (or a string), often one wrapped around a pulley.

4.5 Ropes and Pulleys

Problems that involve ropes and pulleys are very common. In this chapter, we consider only massless (idealized) ropes and pulleys. Whenever a rope is involved, the direction of the force due to the pull on the rope acts exactly in the direction along the rope. The force with which we pull on the massless rope is transmitted through the entire rope unchanged. The magnitude of this force is referred to as the *tension* in the rope. Every rope can withstand only a certain maximum force, but for now we will assume that all applied forces are below this limit. Ropes cannot support a *compression* force.

If a rope is guided over a pulley, the direction of the force is changed, but the magnitude of the force is still the same everywhere inside the rope. In Figure 4.8, the right end of the green rope was tied down and someone pulled on the other end with a certain force, 11.5 N, as indicated by the inserted force measurement devices. As you can clearly see, the magnitude of the force on both sides of the pulley is the same. (The weight of the force measurement devices themselves is a small real-world complication, but enough pulling force was used that it is reasonably safe to neglect this effect.)

FIGURE 4.8 A rope passing over a pulley with force measurement devices attached, showing that the magnitude of the force is constant throughout the rope.

W. Bauer and G. D. Westfall

EXAMPLE 4.1 Modified Tug-of-War

In a tug-of-war competition, two teams try to pull each other across a line. If neither team is moving, then the two teams exert equal and opposite forces on a rope. This is an immediate consequence of Newton's Third Law. That is, if the team shown in Figure 4.9 pulls on the rope with a force of magnitude F, the other team necessarily has to pull on the rope with a force of the same magnitude but in the opposite direction.

FIGURE 4.9 Men competing in a tug-of-war competition at Braemar Games Highland Gathering, Scotland, UK.

Tim Graham/Alamy Stock Photo

PROBLEM

Now let's consider the situation where three ropes are tied together at one point, with a team pulling on each rope. Suppose team 1 is pulling due west with a force of 2750 N, and team 2 is pulling due north with a force of 3630 N. Can a third team pull in such a way that the three-team tug-of-war ends at a standstill, that is, no team is able to move the rope? If yes, what is the magnitude and direction of the force needed to accomplish this?

SOLUTION

The answer to the first question is yes, no matter with what force and in what direction teams 1 and 2 pull. This is the case because the two forces will always add up to a combined force, and all

that team 3 has to do is pull with a force equal to and opposite in direction to that combined force. Then all three forces will add up to zero, and by Newton's First Law, the system has achieved static equilibrium. Nothing will accelerate, so if the ropes start at rest, nothing will move.

Figure 4.10 represents this physical situation. The vector addition of forces exerted by teams 1 and 2 is particularly simple, because the two forces are perpendicular to each other. We choose a conventional coordinate system with its origin at the point where all the ropes meet, and we designate north to be in the positive y-direction and west to be in the negative x-direction. Thus, the force vector for team 1, $\overrightarrow{F_1}$, points in the negative x-direction and the force vector for team 2, $\overrightarrow{F_2}$, points in the positive y-direction. We can now write the two force vectors and their sum as follows:

$$\overrightarrow{F_1} = -(2750\ \text{N})\hat{x}$$

$$\overrightarrow{F_2} = (3630\ \text{N})\hat{y}$$

$$\overrightarrow{F_1} + \overrightarrow{F_2} = -(2750\ \text{N})\hat{x} + (3630\ \text{N})\hat{y}.$$

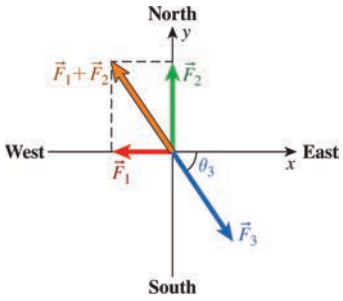

FIGURE 4.10 Addition of force vectors in the three-team tug-of-war.

The addition was made easier by the fact that the two forces pointed along the chosen coordinate axes. However, more general cases of two forces can be added in terms of their components. Because the sum of all three forces has to be zero

for a standstill, we obtain the force that the third team has to exert:

$$\begin{aligned} 0 &= \overrightarrow{F_1} + \overrightarrow{F_2} + \overrightarrow{F_3} \\ \Leftrightarrow \overrightarrow{F_3} &= -\left(\overrightarrow{F_1}, +, \overrightarrow{F_2}\right) \\ &= \left(2750\text{ N}\right)\hat{x} - \left(3630\text{ N}\right)\hat{y}. \end{aligned}$$

This force vector is also shown in Figure 4.10. Having the Cartesian components of the force vector we were looking for, we can get the magnitude and direction by using trigonometry:

$$\begin{aligned} F_3 &= \sqrt{F_{3,x}^2 + F_{3,y}^2} = \sqrt{\left(2750\text{ N}\right)^2 + \left(-3630\text{ N}\right)^2} = 4554\text{ N} \\ \theta_3 &= \tan^{-1}\left(\frac{F_{3,y}}{F_{3,x}}\right) = \tan^{-1}\left(\frac{-3630\text{ N}}{2750\text{ N}}\right) = -52.9^\circ. \end{aligned}$$

These results complete our answer.

Because this type of problem occurs frequently, let's work through another example.

EXAMPLE 4.2 Still Rings

A gymnast of mass 55 kg hangs vertically from a pair of parallel rings (Figure 4.11a).

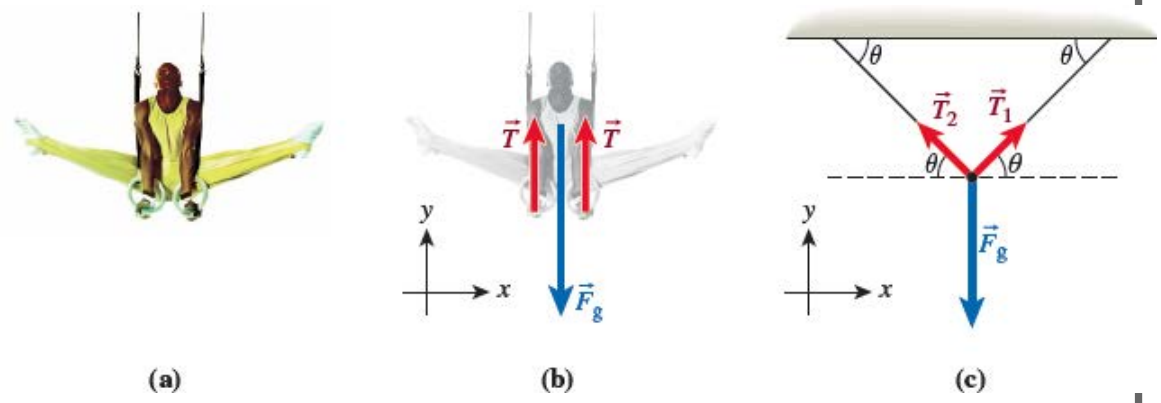

FIGURE 4.11 (a) Still rings in men's gymnastics. (b) Free-body diagram for problem 1. (c) Free-body diagram for problem 2.

a-b: Chad Baker/Jason Reed/Ryan McVay/Getty Images

PROBLEM 1

If the ropes supporting the rings are vertical and attached to the ceiling directly above, what is the tension in each rope?

SOLUTION 1

In this example, we define the x-direction to be horizontal and the y-direction to be vertical. The free-body diagram is shown Figure 4.11b. For now, there are no forces in the x-direction. In the y-direction, we have $\sum_i F_{y,i} = T_1 + T_2 - mg = 0$. Because both ropes support the gymnast equally, the tension has to be the same in both ropes, $T_1 = T_2 \equiv T$, and we get

$$T + T - mg = 0$$
$$\Rightarrow T = \tfrac{1}{2}mg = \tfrac{1}{2}(55\ \text{kg})\left(9.81\ \text{m/s}^2\right) = 270\ \text{N}.$$

PROBLEM 2

If the ropes are attached so that they make an angle $\theta = 45^\circ$ with the ceiling (Figure 4.11c), what is the tension in each rope?

SOLUTION 2

In this part, forces do occur in both x- and y-directions. We will work in terms of a general angle and then plug in the specific angle, $\theta = 45^\circ$, at the end.

In the x-direction, we have for our equilibrium condition:

$$\sum_i F_{x,i} = T_1 \cos\theta - T_2 \cos\theta = 0.$$

In the y-direction, our equilibrium condition is

$$\sum_i F_{y,i} = T_1 \sin\theta + T_2 \sin\theta - mg = 0.$$

From the equation for the x-direction, we again get $T_1 = T_2 \equiv T$, and from the equation for the y-direction, we then obtain:

$$2T \sin\theta - mg = 0 \Rightarrow T = \frac{mg}{2\sin\theta}.$$

Putting in the numbers, we obtain the tension in each rope:

$$T = \frac{(55\ \text{kg})\left(9.81\ \text{m/s}^2\right)}{2\sin\ 45^\circ} = 382\ \text{N}$$

PROBLEM 3

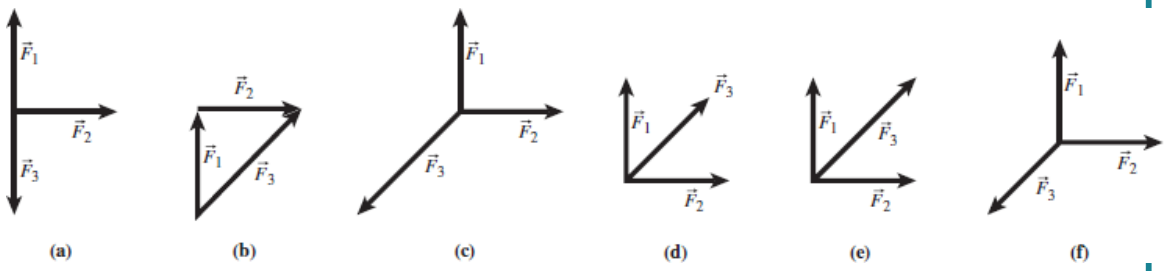
How does the tension in the ropes change as the angle θ between the ceiling and the ropes becomes smaller and smaller?

SOLUTION 3

As the angle θ between the ceiling and the ropes becomes smaller, the tension in the ropes, $T = mg/2\sin\theta$, gets larger. As θ approaches zero, the tension becomes infinitely large. In reality, of course, the gymnast has only finite strength and cannot hold his position with small angles.

Concept Check 4.3

Choose the set of three coplanar vectors that sum to a net force of zero: $\overrightarrow{F_1} + \overrightarrow{F_2} + \overrightarrow{F_3} = 0$.



Force Multiplier

Ropes and pulleys can be combined to lift objects that are too heavy to lift otherwise. In order to see how this can be done, consider Figure 4.12. The system shown consists of rope 1, which is tied to the ceiling (upper right) and then guided over pulleys B and A. Pulley A is also tied to the ceiling with rope 2. Pulley B is free to move vertically and is attached to rope 3. The object of mass m, which we want to lift, is hanging from the other end of rope 3. We assume that the two pulleys have negligible mass and that rope 1 can glide across the pulleys without friction.

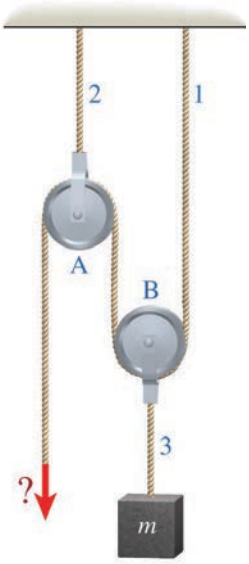


FIGURE 4.12
Rope guided over two pulleys.

What force do we need to apply to the free end of rope 1 to keep the system in static equilibrium? We will call the tension force in rope 1, $\overrightarrow{T_1}$, that in rope 2, $\overrightarrow{T_2}$, and that in rope 3, $\overrightarrow{T_3}$. Again, the key idea is that the magnitude of this tension force is the same everywhere in a given rope.

Figure 4.13 again shows the system in Figure 4.12, but with dashed lines and shaded areas, indicating the free-body diagrams of the two pulleys and the object of mass m. We start with the mass m. For the condition of zero net force to be fulfilled, we need

$$\vec{T}_3 + \vec{F}_g = 0$$

or

$$F_g = mg = T_3.$$

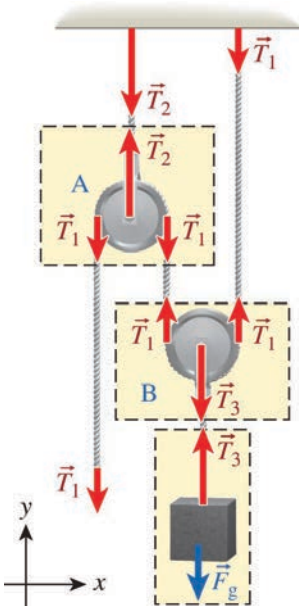

FIGURE 4.13 Free-body diagrams for the two pulleys and the mass to be lifted.

From the free-body diagram of pulley B, we see that the tension force applied from rope 1 acts on both sides of pulley B. This tension has to balance the tension from rope 3, giving pus

$$2T_1 = T_3.$$

Combining the last two equations, we see that

$$T_1 = \frac{1}{2}mg.$$

This result means that the force we need to apply to suspend the object of mass m in this way is only half as large as the force we

would have to use to simply hold it up with a rope, without pulleys. This change in force is why a pulley is called a *force multiplier*.

Even greater force multiplication is achieved if rope 1 passes a total of n times over the same two pulleys. In this case, the force needed to suspend the object of mass m is

$$T = \frac{1}{2n} mg. \qquad \textbf{(4.9)}$$

Figure 4.14 shows the situation for the lower pulley in Figure 4.13 with $n = 3$. This arrangement results in $2n = 6$ force arrows of magnitude T pointing up, able to balance a downward force of magnitude $6T$, as expressed by equation 4.9.

FIGURE 4.14 Pulley with three loops.

Concept Check 4.4

Using a pulley pair with two loops, we can lift a weight of 440 N. If we add two loops to the pulley, with the same force, we can lift

a) half the weight.

b) twice the weight.

c) one-fourth the weight.

d) four times the weight.

e) the same weight.

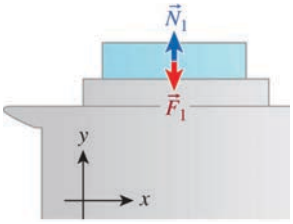
4.6 Applying Newton's Laws

Now let's look at how Newton's laws allow us to solve various kinds of problems involving force, mass, and acceleration. We will make frequent use of free-body diagrams and will assume massless ropes and pulleys. We will also neglect friction for now but will consider it in Section 4.7.

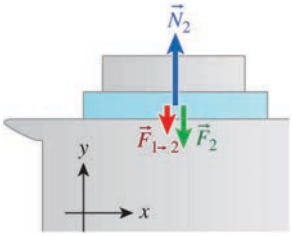
EXAMPLE 4.3 Two Books on a Table

We have considered the simple situation of one object (a laptop computer) supported from below and held at rest. Now let's look at two objects at rest: two books on a table (Figure 4.15a).

(a)



(b)



(c)

FIGURE 4.15 (a) Two books on top of a table. (b) Free-body diagram for book 1. (c) Free-body diagram for book 2.

a: W. Bauer and G. D. Westfall

PROBLEM

What is the magnitude of the force that the table exerts on the lower book?

SOLUTION

We start with a free-body diagram of the book on top, book 1 (Figure 4.15b). This situation is the same as that of the laptop computer held steady by the hand. The gravitational force due to the Earth's attraction that acts on the upper book is indicated by $\vec{F}_1$. It has the magnitude $m_1 g$, where m_1 is the mass of the upper book, and it points straight down. The magnitude of the normal force, $\vec{N}_1$, that the lower book exerts on the upper book from below is then $N_1 = F_1 = m_1 g$, from the condition of zero net force on the upper book (Newton's First Law). The force $\vec{N}_1$ points straight up, as shown in the free-body diagram, $\vec{N}_1 = -\vec{F}_1$.

Newton's Third Law now allows us to calculate the force that the upper book exerts on the lower book. This force is equal in magnitude and opposite in direction to the force that the lower book exerts on the upper one:

$$\vec{F}_{1\to 2} = -\vec{N}_1 = -\left(-\vec{F}_1\right) = \vec{F}_1.$$

This relationship says that the force that the upper book exerts on the lower one is exactly equal to the gravitational force acting on the upper book—that is, its weight. You may find this result trivial at this point, but the application of this general principle allows us to analyze and do calculations for complicated situations.

Now consider the free-body diagram of the lower book, book 2 (Figure 4.15c). This free-body diagram allows us to calculate the normal force that the table exerts on the lower book. We sum up all the forces acting on this book:

$$\vec{F}_{1\to 2} + \vec{N}_1 + \vec{F}_2 = 0 \Rightarrow \vec{N}_2 = -\left(\vec{F}_{1\to 2}, +, \vec{F}_2\right) = -\left(\vec{F}_1, -\right.$$

where $\overrightarrow{N}_2$ is the normal force exerted by the table on the lower book, $\overrightarrow{F}_{1\to 2}$ is the force exerted by the upper book on the lower book, and $\overrightarrow{F}_2$ is the gravitational force on the lower book. In the last step, we used the result we obtained from the free-body diagram of book 1. This result means that the force that the table exerts on the lower book is exactly equal in magnitude and opposite in direction to the sum of the weights of the two books.

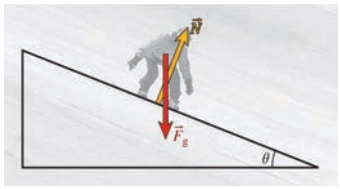
The use of Newton's Second Law enables us to perform a wide range of calculations involving motion and acceleration. The following problem is a classic example: Consider an object of mass m located on a plane that is inclined at an angle θ relative to the horizontal. Assume that there is no friction force between the plane and the object. What can Newton's Second Law tell us about this situation?

SOLVED PROBLEM 4.1 Snowboarding

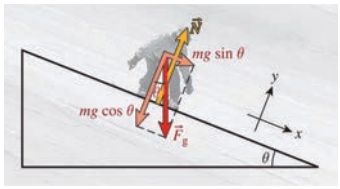
PROBLEM

A snowboarder (mass 72.9 kg, height 1.79 m) glides down a slope with an angle of 22° with respect to the horizontal (Figure 4.16a). If we can neglect friction, what is his acceleration?

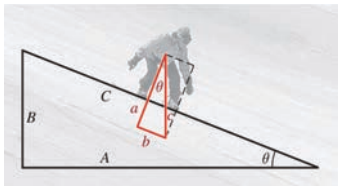
(a)



(b)



(c)



(d)

FIGURE 4.16 (a) Snowboarding as an example of motion on an inclined plane. (b) Free-body diagram of the snowboarder on the inclined plane. (c) Free-body diagram of the snowboarder, with a coordinate system added. (d) Similar triangles in the inclined-plane problem.

a-d: W. Bauer and G. D. Westfall

SOLUTION

THINK

The motion is restricted to motion along the slope (or inclined plane) because the snowboarder cannot sink into the snow, and he cannot lift off from its surface. (At least not without jumping!) It is always advisable to start with a free-body diagram. Figure 4.16b shows the force vectors for gravity, $\vec{F}_g$, and the normal force, $\vec{N}$. Note that the normal force vector is directed perpendicular to the contact surface, as required by the definition of the normal force. Also observe that the normal force and the force of gravity do not point in exactly opposite directions and thus do not cancel each other out completely.

SKETCH

Now we pick a convenient coordinate system. As shown in Figure 4.16c, we choose a coordinate system with the x-axis along the direction of the inclined plane. This choice ensures that the acceleration is only in the x-direction. Another advantage of this choice of coordinate system is that the normal force is pointing exactly in the y-direction. The price we pay for this convenience is that the gravitational force vector does not point along one of the major axes in our coordinate system but has an x- and a y-component. The red arrows in the figure indicate the two components of the gravitational force vector. Note that the angle of inclination of the plane, θ, also appears in the rectangle constructed from the two components of the gravity force vector, which is the diagonal of that rectangle. You can see this relationship by considering the similar triangles with sides abc and ABC in Figure 4.16d. Because a is perpendicular to C and c is perpendicular to A, it follows that the angle between a and c is the same as the angle between A and C.

RESEARCH

The x- and y-components of the gravitational force vector are found from trigonometry:

$$F_{\mathrm{g},x} = F_{\mathrm{g}} \sin\theta = mg \sin\theta$$
$$F_{\mathrm{g},y} = -F_{\mathrm{g}} \cos\theta = -mg \cos\theta.$$

SIMPLIFY

Now we do the math in a straightforward way, separating calculations by components.

First, there is no motion in the y-direction, which means that, according to Newton's First Law, all the external force components in the y-direction have to add up to zero:

$$F_{\mathrm{g},y} + N = 0 \Rightarrow$$
$$-mg \cos\theta + N = 0 \Rightarrow$$
$$N = mg \cos\theta.$$

Our analysis of the motion in the y-direction has given us the magnitude of the normal force, which balances the component of the weight of the snowboarder perpendicular to the slope. This is a very typical result. The normal force almost always balances the net force perpendicular to the contact surface that is contributed by all other forces. Thus, objects do not sink into or lift off from surfaces.

The information we are interested in comes from looking at the x-direction. In this direction, there is only one force component, the x-component of the gravitational force. Therefore, according to Newton's Second Law, we obtain

$$F_{g,x} = mg \sin\theta = ma_x \Rightarrow$$
$$a_x = g \sin\theta.$$

Thus, we now have the acceleration vector in the specified coordinate system:

$$\vec{a} = (g \sin\theta)\hat{x}.$$

Note that the mass, m, dropped out of our answer. The acceleration does not depend on the mass of the snowboarder; it depends only on the angle of inclination of the plane. Thus, the

mass of the snowboarder given in the problem statement turns out to be just as irrelevant as his height.

CALCULATE

Putting in the given value for the angle leads to

$$a_x = \left(9.81\ \mathrm{m/s^2}\right)(\sin 22^\circ) = 3.67489\ \mathrm{m/s^2}.$$

ROUND

Because the angle of the slope was given to only two-digit accuracy, it makes no sense to give our result to a greater precision. The final answer is

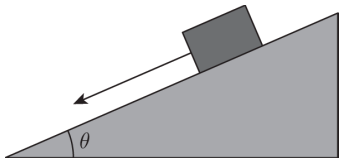
$$\mathrm{a}_x = 3.7\ \mathrm{m/s^2}.$$

DOUBLE-CHECK

The units of our answer, $\mathrm{m/s^2}$, are those of acceleration. The number we obtained is positive, which means a positive acceleration down the slope in the coordinate system we have chosen. Also the number is less than 9.81, which is comforting. It means that our calculated acceleration is less than that for free fall. As a final step, let's check for consistency of our answer, $a_x = g \sin\theta$, in limiting cases. In the case where $\theta \to 0^\circ$, the sine also converges to zero, and the acceleration vanishes. This result is consistent because we expect no acceleration of the snowboarder if he rests on a horizontal surface. As $\theta \to 90^\circ$, the sine approaches 1, and the acceleration is the acceleration due to gravity, as we expect as well. In this limiting case, the snowboarder would be in free fall.

Concept Check 4.5

A block with mass *m* is on a frictionless inclined plane as shown.



The magnitude of the component of the force of gravity acting parallel to the surface of the inclined plane represented by the arrow is

a) *mg*.

b) *mg* sin θ.

c) *mg* cos θ.

d) none of these.

Inclined-plane problems, like the one we have just solved, are very common and provide practice with component decomposition of forces. Another common type of problem involves redirection of forces via pulleys and ropes. The next solved problem shows how to proceed in a simple case.

SOLVED PROBLEM 4.2 Two Blocks Connected by a Rope

In this classic problem, a hanging mass causes the acceleration of a second mass that is resting on a horizontal surface (Figure 4.17a). Block 1, of mass $m_1 = 3.00\,\text{kg}$, rests on a horizontal frictionless surface and is connected via a massless rope (for simplicity, oriented in the horizontal direction) running over a massless pulley to block 2, of mass $m_2 = 1.30\,\text{kg}$.

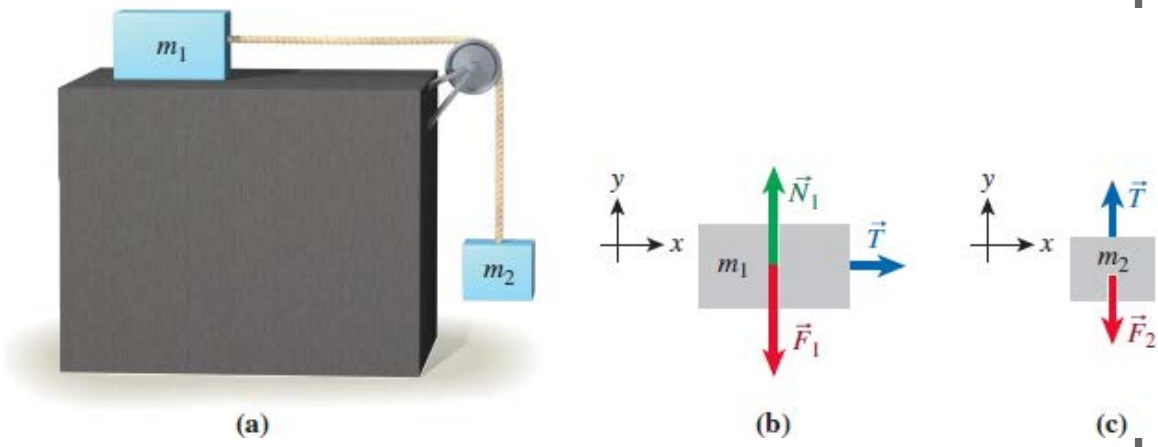


FIGURE 4.17 (a) Block 2 hanging vertically from a rope that runs over a pulley and is connected to block 1, resting on a horizontal frictionless surface. (b) Free-body diagram for block 1. (c) Free-body diagram for block 2.

PROBLEM

What is the acceleration of block 1 and of block 2?

SOLUTION

THINK

From the figure, it is clear that block 1 can only move horizontally and that block 2 can only move vertically. Since the two blocks are connected by a rope, they exert a force on each other via the tension in the rope. Newton's Third Law tells us that the magnitude of the tension acting on either block is the same. We also assume that the rope does not stretch appreciably. This means that any displacement of block 1 results in a displacement

of equal magnitude of block 2. This also means that the blocks have the same speed at any time and thus their accelerations have the same magnitude, a. Finally, let's think about the sign of the acceleration: If block 1 moves to the right, then block 2 moves down. It is important to note this consequence, because otherwise sign errors can creep into our calculations.

SKETCH

Again, we start with a free-body diagram for each object. For block 1, the free-body diagram is shown in Figure 4.17b. The gravitational force vector, F_1, points straight down. The tension force in the rope, $\vec{T}$ acts along the direction of the rope and thus is in the horizontal direction, which we have chosen as the x-direction. The normal force, $\vec{N}_1$, acting on block 1 is perpendicular to the contact surface between that block and the supporting surface. Because the surface is horizontal, $\vec{N}_1$ acts in the vertical direction. Figure 4.17c shows the free-body diagram for block 2. The tension force, $\vec{T}$, acts in the upward direction, and the gravitational force vector, $\vec{F}_2$, acting on this block points straight down, just like $\vec{F}_1$.

RESEARCH

Let's start with the forces acting on block 1 and write the equations (based on Newton's Second Law) for the x- and y-components:

$$T = m_1 a$$
$$N_1 - m_1 g = 0.$$

The second equation just tells us that the normal force acting on block 1 is equal to the weight of block 1. However, the first equation contains the acceleration, a, which we want to find. All we have to do now is to find the tension, T.

The free-body diagram for block 2 allows us to write one more equation. In the horizontal direction, there are no forces acting on it, but in the vertical direction, from Newton's Second Law, we have

$$T - m_2 g = -m_2 a.$$

Note the negative sign on the right side! As block 1 accelerates in the positive x-direction (to the right), block 2 has to accelerate in the negative y-direction (downward).

SIMPLIFY

We substitute from $T = m_1 a$ into $T - m_2 g = -m_2 a$ and find

$$T - m_2 g = m_1 a - m_2 g = -m_2 a \Rightarrow m_1 a + m_2 a = m_2 g \Rightarrow$$
$$a = g \frac{m_2}{m_1 + m_2}.$$

CALCULATE

Now all we have to do is insert the values for the masses:

$$a = \left(9.81 \text{ m/s}^2\right) \frac{1.30 \text{ kg}}{3.00 \text{ kg} + 1.30 \text{ kg}} = 2.96581 \text{ m/s}^2.$$

ROUND

Since the gravitational acceleration was given to only three significant digits and the masses were specified to the same precision, we round our result to $a = 2.97 \text{ m/s}^2$.

DOUBLE-CHECK

This result makes sense: In the limit where m_1 is very large compared to m_2, there will be almost no acceleration, whereas if m_1 is very small compared to m_2, then m_2 will accelerate with almost the full acceleration due to gravity, as if m_1 were not there.

Finally, we can calculate the magnitude of the tension by substituting our result for the acceleration into one of the two equations we obtained using Newton's Second Law:

$$T = m_1 a = g\frac{m_1 m_2}{m_1 + m_2}.$$

In Solved Problem 4.2, it is clear in which direction the acceleration will occur. In more complicated cases, the direction in which objects begin to accelerate may not be clear at the beginning. You just have to define a direction as positive and use this assumption consistently throughout your calculations. If the acceleration value you obtain in the end turns out to be negative, this result means that the objects accelerate in the direction opposite to the one you initially assumed. The calculated value will remain correct. Example 4.4 illustrates such a situation.

EXAMPLE 4.4 Atwood Machine

The Atwood machine consists of two hanging weights (with masses m_1 and m_2) connected via a rope running over a pulley. For now, we consider a friction-free case, where the pulley does not move, and the rope glides over it. (In Chapter 10 on rotation, we will return to this problem and solve it with friction present, which causes the pulley to rotate.) We also assume that $m_1 > m_2$. In this case, the acceleration is as shown in Figure 4.18a. (The formula derived in the following is correct for any case. If $m_1 < m_2$, then the value of the acceleration, a, will have a negative sign, which will mean that the acceleration direction is opposite to what we have assumed in working the problem.)

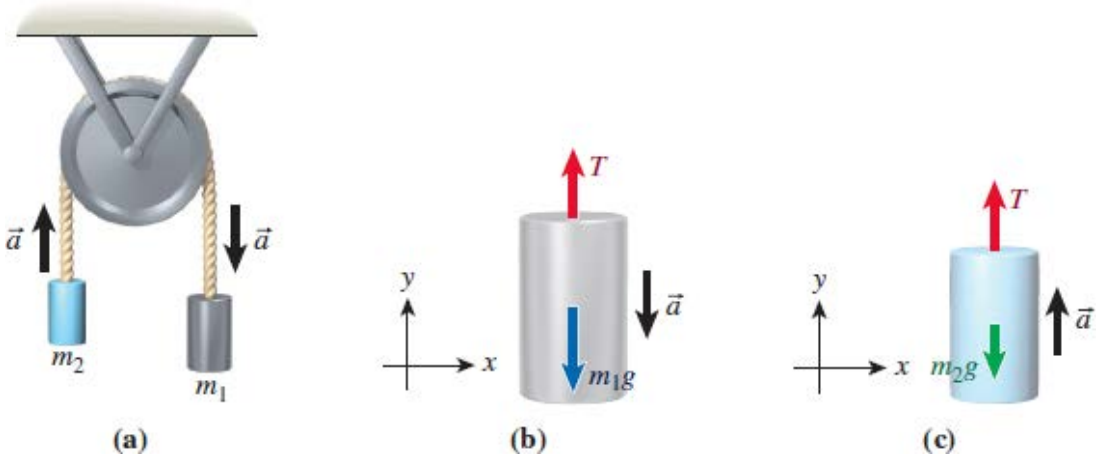

FIGURE 4.18 (a) Atwood machine with the direction of positive acceleration assumed to be as indicated. (b) Free-body diagram for the weight on the right side of the Atwood machine. (c) Free-body diagram for the weight on the left side of the Atwood machine.

We start with free-body diagrams for m_1 and m_2, as shown in Figure 4.18b and Figure 4.18c. For both free-body diagrams, we elect to point the positive y-axis upward, and both diagrams show our choice for the direction of the acceleration. The rope exerts a tension T, of magnitude still to be determined, upward

on both m_1 and m_2. With our choices of coordinate system and acceleration direction, the downward acceleration of m_1 is acceleration in a negative direction. This leads to an equation that can be solved for T:

$$T - m_1 g = -m_1 a \Rightarrow T = m_1 g - m_1 a = m_2 (g - a).$$

From the free-body diagram for m_2 and the assumption that the upward acceleration of m_2 corresponds to acceleration in a positive direction, we get

$$T - m_2 g = m_2 a \Rightarrow T = m_2 g + m_2 a = m_2 (g + a).$$

Equating the two expressions for T, we obtain

$$m_1(g - a) = m_2(g + a)$$

which leads to an expression for the acceleration:

$$(m_1 - m_2)g = (m_1 + m_2)a \Rightarrow$$
$$a = g\left(\frac{m_1 - m_2}{m_1 + m_2}\right).$$

From this equation, you can see that the magnitude of the acceleration, a, is always smaller than g in this situation. If the masses are equal, we obtain the expected result of no acceleration. By selecting the proper combination of masses, we can generate any value of acceleration between zero and g that we desire.

Self-Test Opportunity 4.2

What is the acceleration of the masses on the Atwood machine at the limits where m_1 approaches infinity, m_1 approaches zero, and $m_1 = m_2$?

Self-Test Opportunity 4.3

For the Atwood machine, can you write a formula for the magnitude of the tension in the rope?

Concept Check 4.6

If you double both masses in an Atwood machine, the resulting acceleration will be

a) twice as large.

b) half as large.

c) the same.

d) one-quarter as large.

e) four times as large.

Concept Check 4.7

An Atwood machine is a frictionless pulley with two masses, m_1 and m_2, connected by a string as shown.

The mass of the object m_1 is twice the mass of the object m_2, and the masses are moving.

The tension T in the string connected to m_2 is

a) $T = m_2 g$.

b) $T = m_1 g$.

c) neither of these.

EXAMPLE 4.5 Collision of Two Vehicles

Suppose that an SUV of mass $m = 3260$ kg has a head-on collision with a subcompact car of mass $m = 1194$ kg and exerts a force of magnitude $2.9 \cdot 10^5$ N on the subcompact.

PROBLEM

What is the magnitude of the force that the subcompact exerts on the SUV in the collision?

SOLUTION

As paradoxical as it may seem at first, the little subcompact exerts just as much force on the SUV as the SUV exerts on it. This equality is a straightforward consequence of Newton's Third Law, equation 4.8. So, the answer is $2.9 \cdot 10^5$ N.

DISCUSSION

The answer may be straightforward, but it is by no means intuitive. The subcompact will usually sustain much more damage in such a collision, and its passengers will have a much bigger chance of getting hurt. However, this difference is due to Newton's Second Law, which says that the same force applied to a less massive object yields a higher acceleration than if applied to a more massive one. Even in a head-on collision between a mosquito and a car on the freeway, the forces exerted on each body are equal; the difference in damage to the car (none) and to the mosquito (obliteration) is due to their different resulting accelerations and the fact that the mosquito's body is made of organic matter and thus much more easily damaged than the car's windshield. We will revisit collisions in Chapter 7.

Concept Check 4.8

For the collision in Example 4.5, if we call the absolute value of the acceleration experienced by the SUV a_{SUV} and that for the subcompact car a_{car}, we find that approximately

a) $a_{SUV} \approx \frac{1}{9} a_{car}$.

b) $a_{SUV} \approx \frac{1}{3} a_{car}$.

c) $a_{SUV} \approx a_{car}$.

d) $a_{SUV} \approx 3a_{car}$.

e) $a_{SUV} \approx 9a_{car}$.

4.7 Friction Force

So far, we have neglected the force of friction and considered only frictionless approximations. However, in general, we have to include friction in most of our calculations when we want to describe physically realistic situations.

We could conduct a series of very simple experiments to learn about the basic characteristics of friction. Here are the findings we would obtain:

- If an object is at rest, it takes an external force with a certain threshold magnitude and acting parallel to the contact surface between the object and the surface to overcome the friction force and make the object move.
- The friction force that has to be overcome to make an object at rest move is larger than the friction force that has to be overcome to keep the object moving at a constant velocity.
- The magnitude of the friction force acting on a moving object is proportional to the magnitude of the normal force.
- The friction force is independent of the size of the contact area between object and surface.
- The friction force depends on the roughness of the surfaces; that is, a smoother interface generally provides less friction force than a rougher one.
- The friction force is independent of the velocity of the object.

These statements about friction are not principles in the same way as Newton's laws. Instead, they are general observations based on experiments. For example, you might think that the contact of two extremely smooth surfaces would yield very low friction. However, in some cases, extremely smooth surfaces actually fuse together as a cold weld. Investigations into the nature and causes of friction continue, as we discuss later in this section.

From these findings, it is clear that we need to distinguish between the case where an object is at rest relative to its supporting surface (static friction) and the case where an object is moving across

the surface (kinetic friction). The case in which an object is moving across a surface is easier to treat, and so we consider kinetic friction first.

Kinetic Friction

The above general observations can be summarized in the following approximate formula for the magnitude of the kinetic friction force, f_k:

$$f_k = \mu_k N. \tag{4.10}$$

Here N is the magnitude of the normal force and μ_k is the **coefficient of kinetic friction**. This coefficient is always equal to or greater than zero. (The case where $\mu_k = 0$ corresponds to a frictionless approximation. In practice, however, it can never be reached perfectly.) In almost all cases, μ_k is also less than 1. (Some special tire surfaces used for car racing, though, have a coefficient of friction with the road that can significantly exceed 1.) Some representative coefficients of kinetic friction are shown in Table 4.1.

Table 4.1	Typical Coefficients of Both Static and Kinetic Friction Between Material 1 and Material 2*		
Material 1	**Material 2**	μ_s	μ_k
rubber	dry concrete	1	0.8
rubber	wet concrete	0.7	0.5
steel	steel	0.7	0.6
wood	wood	0.5	0.3
waxed ski	snow	0.1	0.05
steel	oiled steel	0.12	0.07
Teflon	steel	0.04	0.04
curling stone	ice		0.017

*Note that these values are approximate and depend strongly on the condition of the contact surface between the two materials.

The direction of the kinetic friction force is *always opposite to the direction of motion* of the object relative to the surface it moves on.

If you push an object with an external force parallel to the contact surface, and the force has a magnitude exactly equal to that of the force of kinetic friction on the object, then the total net external force is zero, because the external force and the friction force cancel each other. In that case, according to Newton's First Law, the object will continue to slide across the surface with constant velocity.

Static Friction

If an object is at rest, it takes a certain threshold amount of external force to set it in motion. For example, if you push lightly against a refrigerator, it will not move. As you push harder and harder, you reach a point where the refrigerator finally slides across the kitchen floor.

For any external force acting on an object that remains at rest, the friction force is exactly equal in magnitude and opposite in direction to the component of that external force that acts along the contact surface between the object and its supporting surface. However, the magnitude of the static friction force has a maximum value: $f_{\mathrm{s}} \leq f_{\mathrm{s,max}}$. This maximum magnitude of the static friction force is proportional to the normal force, but with a different proportionality constant than the coefficient of kinetic friction: $f_{\mathrm{s,max}} = \mu_{\mathrm{s}} N$. For the magnitude of the force of static friction, we can write

$$f_{\mathrm{s}} \leq \mu_{\mathrm{s}} N = f_{\mathrm{s,max}}, \tag{4.11}$$

where μ_{s} is called the **coefficient of static friction**. Some typical coefficients of static friction are shown in Table 4.1. In general, for any object on any supporting surface, the maximum static friction force is greater than the force of kinetic friction. You may have experienced this when trying to slide a heavy object across a surface: As soon as the object starts moving, a lot less force is required to keep it in constant sliding motion. We can express this finding as a mathematical inequality between the two coefficients:

$$\mu_{\mathrm{s}} > \mu_{\mathrm{k}}. \tag{4.12}$$

Figure 4.19 presents a graph showing how the friction force depends on an external force, F_{ext}, applied to an object. If the object is initially at rest, a small external force results in a small force of friction, rising linearly with the external force until it reaches a value of $\mu_{\mathrm{s}} N$. Then it drops rather quickly to a value of $\mu_{\mathrm{k}} N$ when the object is set in motion. At this point, the external force has a value of $F_{\mathrm{ext}} = \mu_{\mathrm{s}} N$, resulting in a sudden acceleration of the object. This

dependence of the friction force on the external force is shown in Figure 4.19 as a red line.

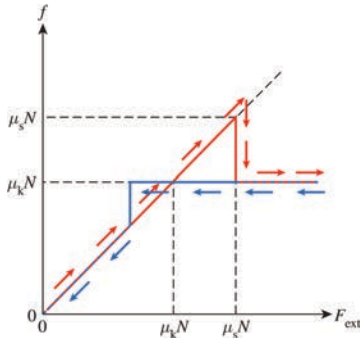

FIGURE 4.19
Magnitudes of the forces of friction as a function of the magnitude of an external force. The red line represents the forces for an object initially at rest, with the external force increasing from zero. The blue line represents the forces for an object initially in motion under the influence of an external force that is larger than the friction force but is then gradually reduced.

On the other hand, if we start with a large external force and the object is already in motion, then we can reduce the external force below a value of $\mu_s N$, but still above $\mu_k N$, and the object will keep moving and accelerating. Thus, the friction coefficient retains a value

of μ_k until the external force is reduced to a value of $\mu_k N$. At this point (and only at this point!), the object will move with a constant velocity, because the external force and the friction force are equal in magnitude. If we reduce the external force further, the object decelerates (horizontal segment of the blue line left of the red diagonal in Figure 4.19), because the kinetic friction force is bigger than the external force. Eventually, the object comes to rest because of the kinetic friction, and the external force is not sufficient to move it anymore. Then static friction takes over, and the friction force is reduced proportionally to the external force until both reach zero. The blue line in Figure 4.19 illustrates this dependence of the friction force on the external force. Where the blue line and the red line overlap, this is indicated by alternating blue and red dashes. The most interesting feature of Figure 4.19 is that the blue and red lines do not coincide between $\mu_k N$ and $\mu_s N$.

Let's return to the attempt to move a refrigerator across the kitchen floor. Initially, the refrigerator sits on the floor, and the static friction force resists your effort to move it. Once you push hard enough, the refrigerator jars into motion. In this process, the friction force follows the red path in Figure 4.19. Once the refrigerator moves, you can push less hard and still keep it moving. If you push with less force so that it moves with constant velocity, the external force you apply follows the blue path in Figure 4.19 until it is reduced to $F_{\text{ext}} = \mu_k N$. Then the friction force and the force you apply to the fridge add up to zero, and there is no net force acting on the refrigerator, allowing it to move with constant velocity.

EXAMPLE 4.6 Realistic Snowboarding

Let's reconsider the snowboarding situation from Solved Problem 4.1, but now include friction. A snowboarder moves down a slope for which $\theta = 22^\circ$. Suppose the coefficient of kinetic friction between his board and the snow is 0.21, and his velocity, which is along the direction of the slope, is measured as 8.3 m/s at a given instant.

PROBLEM 1

Assuming a constant slope, what will be the speed of the snowboarder along the direction of the slope when he is 100 m farther down the slope?

SOLUTION 1

Figure 4.20 shows a free-body diagram for this problem. The gravitational force points downward and has magnitude mg, where m is the mass of the snowboarder and his equipment. We choose convenient x- and y-axes parallel and perpendicular to the slope, respectively, as indicated in Figure 4.20. The angle θ that the slope makes with the horizontal (22° in this case) also appears in the decomposition of the components of the gravitational force parallel and perpendicular to the slope. (This analysis is a general feature of any inclined-plane problem.) The force component along the plane is then $mg \sin\theta$, as shown in Figure 4.20. The normal force is given by $N = mg \cos\theta$, and the force of kinetic friction is $f_k = -\mu_k mg \cos\theta$, with the minus sign indicating that the force is acting in the negative x-direction, in our chosen coordinate system.

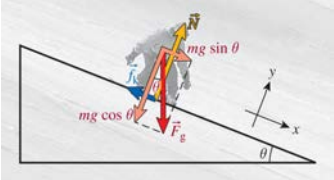

FIGURE 4.20 Free-body diagram of a snowboarder, including the friction force.

W. Bauer and G. D. Westfall

We thus get for the total force component in the x-direction:

$$mg\ \sin\theta - \mu_{\mathrm{k}} mg\ \cos\theta = ma_x \Rightarrow$$
$$a_{\mathrm{x}} = \mathrm{g}(\sin\theta - \mu_{\mathrm{k}}\ \cos\theta).$$

Here we have used Newton's Second Law, $F_x = ma_x$, in the first line. The mass of the snowboarder drops out, and the acceleration, a_x, along the slope is constant. Inserting the numbers given in the problem statement, we obtain

$$a \equiv a_x = \left(9.81\ \mathrm{m/s^2}\right)(\sin 22^\circ - 0.21\ \cos\ 22^\circ) = 1.76\ \mathrm{m/s^2}$$

Thus, we see that this is a problem of motion in a straight line in one direction with constant acceleration. We can apply the relationship between the squares of the initial and final velocities and the acceleration that we have derived for one-dimensional motion with constant acceleration:

$$v^2 = v_0^2 + 2a(x - x_0).$$

With $v_0 = 8.3$ m/s and $x - x_0 = 100$ m, we calculate the final speed:

$$
\begin{aligned}
v &= \sqrt{v_0^2 + 2a(x - x_0)} \\
&= \sqrt{(8.3\ \text{m/s})^2 + 2(1.76\ \text{m/s}^2)(100\ \text{m})} \\
&= 20.5\ \text{m/s}
\end{aligned}
$$

PROBLEM 2

How long does it take the snowboarder to reach this speed?

SOLUTION 2

Since we now know the acceleration and the final speed and were given the initial speed, we use

$$
v = v_0 + at \Rightarrow t = \frac{v - v_0}{a} = \frac{(20.5 - 8.3)\ \text{m/s}}{1.76\ \text{m/s}^2} = 6.9\ \text{s}.
$$

PROBLEM 3

Given the same coefficient of friction, what would the angle of the slope have to be for the snowboarder to glide with constant velocity?

SOLUTION 3

Motion with constant velocity implies zero acceleration. We have already derived an equation for the acceleration as a function of the slope angle. We set this expression equal to zero and solve the resulting equation for the angle θ:

$$
\begin{aligned}
&a_x = g(\sin\theta - \mu_\text{k}\cos\theta) = 0 \\
&\Rightarrow \sin\ \theta = \mu_\text{k}\cos\ \theta \\
&\Rightarrow \tan\ \theta = \mu_\text{k} \\
&\Rightarrow \theta = \tan^{-1}\mu_\text{k}
\end{aligned}
$$

Because $\mu_\text{k} = 0.21$ was given, the angle is $\theta = \tan^{-1} 0.21 = 12^\circ$. With a steeper slope, the snowboarder will accelerate, and with a

shallower slope, the snowboarder will slow down until he comes to a stop.

Air Resistance

So far we have ignored the friction due to moving through the air. Unlike the force of kinetic friction that acts when you drag or push one object across the surface of another, air resistance increases as speed increases. Thus, we need to express the friction force as a function of the velocity of the object relative to the medium it moves through. The direction of the force of air resistance is opposite to the direction of the velocity vector.

In general, the magnitude of the friction force due to air resistance, or **drag force**, can be expressed as $F_{\text{frict}} = K_0 + K_1 v + K_2 v^2 + \ldots$, with the constants K_0, K_1, K_2, ... determined experimentally. For the drag force on macroscopic objects moving at relatively high speeds, we can neglect the linear term in the velocity. The magnitude of the drag force is then approximately

$$F_{\text{drag}} = Kv^2. \tag{4.13}$$

This equation means that the force due to air resistance is proportional to the square of the speed.

When an object falls through air, the force from air resistance increases as the object accelerates until it reaches a **terminal speed**. At this point, the upward force of air resistance and the downward force due to gravity equal each other. Thus, the net force is zero, and there is no more acceleration. Because there is no more acceleration, the falling object has constant terminal speed:

$$F_{\text{g}} = F_{\text{drag}} \Rightarrow m\text{g} = Kv^2.$$

Solving this for the terminal speed, we obtain

$$v = \sqrt{\frac{m\text{g}}{K}}. \tag{4.14}$$

Note that the terminal speed depends on the mass of the object, whereas the mass of the object does not affect the object's motion

when air resistance is neglected. In the absence of air resistance, all objects fall at the same rate, but the presence of air resistance explains why heavy objects fall faster than light ones that have the same (drag) constant *K*.

To compute the terminal speed for a falling object, we need to know the value of the constant *K*. This constant depends on many variables, including the size of the cross-sectional area, *A*, exposed to the air stream. In general terms, the bigger the area, the bigger is the constant *K*. *K* also depends linearly on the air density, ρ. All other dependences on the shape of the object, on its inclination relative to the direction of motion, on air viscosity, and compressibility are usually collected in a drag coefficient, c_{d}:

$$K = \frac{1}{2} c_{\mathrm{d}} A \rho. \qquad \textbf{(4.15)}$$

Equation 4.15 has the factor $\frac{1}{2}$ to simplify calculations involving the energy of objects undergoing free fall with air resistance. We will return to this subject when we discuss kinetic energy in Chapter 5.

Concept Check 4.9

An unused coffee filter reaches its terminal speed very quickly if you let it fall. Suppose you release a single coffee filter from a height of 1 m. From what height do you have to release a stack of two coffee filters at the same instant so that they will hit the ground at the same time as the single coffee filter? (You can safely neglect the time needed to reach terminal speed.)

a) 0.5 m

b) 0.7 m

c) 1 m

d) 1.4 m

e) 2 m

Creating a low drag coefficient is an important consideration in automotive design, because it has a strong influence on the maximum speed of a car and its fuel consumption. Numerical computations are useful, but the drag coefficient is usually optimized experimentally by putting car prototypes into wind tunnels and testing the air resistance at different speeds. The same wind tunnel tests are also used to optimize the performance of equipment and athletes in events such as downhill ski racing and bicycle racing.

For motion in very viscous media or at low velocities, the linear velocity term of the friction force cannot be neglected. In such cases, the friction force can be approximated by the form $F_{\text{frict}} = K_1 v$. This form applies to most biological processes, including motion of large biomolecules or even microorganisms such as bacteria through liquids. This approximation of the friction force is also useful when analyzing the sinking of an object in a fluid, for example, a small stone or fossil shell in water.

EXAMPLE 4.7 Sky Diving

An 80.0-kg skydiver falls through air with a density of 1.15 kg/m^3. Assume that his drag coefficient is $c_d = 0.570$. When he falls in the spread-eagle position, as shown in Figure 4.21a, his body presents an area $A_1 = 0.940\ \text{m}^2$ to the wind, whereas when he dives head first, with arms close to the body and legs together, as shown in Figure 4.21b, his area is reduced to $A_2 = 0.210\ \text{m}^2$.

(a)

(b)

FIGURE 4.21 (a) Skydiver in the high-resistance position. (b) Skydiver in low-resistance position.

a: Digital Vision/Getty Images; **b:** Oliver Furrer/Getty Images

PROBLEM

What are the terminal speeds in both cases?

SOLUTION

We use equation 4.14 for the terminal speed, substitute the expression for the air resistance constant from equation 4.15, and insert the given numbers:

$$v = \sqrt{\frac{mg}{K}} = \sqrt{\frac{mg}{\frac{1}{2}c_{\mathrm{d}}A\rho}}$$

$$v_1 = \sqrt{\frac{(80.0\,kg)\left(9.81\,\mathrm{m/s^2}\right)}{\frac{1}{2}0.570(0.940\,\mathrm{m^2})\left(1.5\,\mathrm{kg/m^3}\right)}} = 50.5\,\mathrm{m/s}$$

$$v_2 = \sqrt{\frac{(80.0\,\mathrm{kg})\left(9.81\,\mathrm{m/s^2}\right)}{\frac{1}{2}0.570(0.210\,\mathrm{m^2})\left(1.5\,\mathrm{kg/m^3}\right)}} = 107\,\mathrm{m/s}.$$

These results show that, by diving head first, the skydiver can reach higher velocities during free fall than when he uses the spread-eagle position. Therefore, it is possible to catch up to a person who has fallen out of an airplane, assuming that the person is not diving head first, too. However, in general, this technique cannot be used to save such a person because it would be nearly impossible to hold onto him or her during the sudden deceleration shock caused by the rescuer's parachute opening.

Tribology

What causes friction? The answer to this question is not at all easy or obvious. When surfaces rub against each other, different atoms (more on atoms in Chapter 13) from the two surfaces make contact with each other in different ways. Atoms get dislocated in the process of dragging surfaces across each other. Electrostatic interactions (more on these in Chapter 21) between the atoms on the surfaces cause additional static friction. A true microscopic understanding of friction is beyond the scope of this book and is currently the focus of great research activity.

The science of friction has a name: **tribology**. The laws of friction we have discussed were already known 300 years ago. Their discovery is generally credited to Guillaume Amontons and Charles Augustin de Coulomb, but even Leonardo da Vinci may have known them. Yet amazing things are still being discovered about friction, lubrication, and wear.

Perhaps the most interesting advance in tribology that occurred in the last two decades was the development of atomic and friction force microscopes. The basic principle that these microscopes employ is the dragging of a very sharp tip across a surface with analysis by cutting-edge computer and sensor technology. Such friction force microscopes can measure friction forces as small as $10\ \mathrm{pN} = 10^{-11}\mathrm{N}$. Figure 4.22a shows a diagram of an atomic force microscope (AFM); Figure 4.22b is a close-up photograph (magnification 1000×) of its cantilever tip. State-of-the-art microscopic simulations of friction are still not able to completely explain it, and so this research area is of great interest in the field of nanotechnology.

a: Eye of Science/Science Source

Friction is responsible for the breaking off of small particles from surfaces that rub against each other, causing wear. This phenomenon is of particular importance in high-performance car engines, which require specially formulated lubricants. Understanding the influence of small surface impurities on the friction force is of great interest in this context. Research into lubricants continues to try to find ways to reduce the coefficient of kinetic friction, μ_k, to a value as close to zero as possible. For example, modern lubricants include *buckyballs*—molecules consisting of 60 carbon atoms arranged in the shape of a soccer ball, which were discovered in 1985. These molecules act like microscopic ball bearings.

Solving problems involving friction is also important to car racing. In the Formula 1 circuit, using the right tires that provide optimally high friction is essential for winning races. While friction coefficients are normally in the range between 0 and 1, it is not unusual for top fuel race cars to have tires that have friction coefficients with the track surface of 3 or even larger.

4.8 Applications of the Friction Force

With Newton's three laws, we can solve a huge class of problems. Knowing about static and kinetic friction allows us to approximate real-world situations and come to meaningful conclusions. Because it is helpful to see various applications of Newton's laws, we will solve several practice problems. These examples are designed to demonstrate a range of techniques that are useful in the solution of many kinds of problems.

EXAMPLE 4.8 Two Blocks Connected by a Rope—with Friction

We solved this problem in Solved Problem 4.2, with the assumptions that block 1 slides without friction across the horizontal support surface and that the rope slides without friction across the pulley. Here we will allow for friction between block 1 and the surface it slides across. For now, we will still assume that the rope slides without friction across the pulley. (Chapter 10 will present techniques that let us deal with the pulley being set into rotational motion by the rope moving across it.)

PROBLEM 1

Let the coefficient of static friction between block 1 (mass $m_1 = 2.3\,\text{kg}$) and its support surface have a value of 0.73 and the coefficient of kinetic friction have a value of 0.60. (Refer back to Figure 4.17.) If block 2 has mass $m_2 = 1.9\,\text{kg}$, will block 1 accelerate from rest?

SOLUTION 1

All the force considerations from Solved Problem 4.2 remain the same, except that the free-body diagram for block 1 (Figure 4.23) now has a force arrow corresponding to the friction force, f. Keep in mind that in order to draw the direction of the friction force, you need to know in which direction movement would occur in the absence of friction. Because we have already solved the frictionless case, we know that block 1 would move to the right. Because the friction force is directed opposite to the movement, the friction vector thus points to the left.

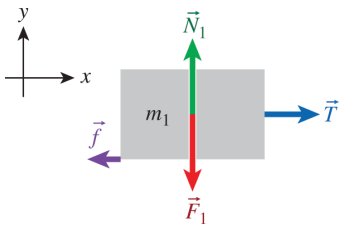

FIGURE 4.23 Free-body diagram for block 1, including the force of friction.

The equation we derived in Solved Problem 4.2 by applying Newton's Second Law to block 1 changes from $m_1a = T$ to

$$m_1a = T - f.$$

Combining this with the equation we obtained in Solved Problem 4.2 via application of Newton's Second Law to $m_2, T - m_2g = -m_2a$, and again eliminating T gives us

$$m_1a + f = T = m_2g - m_2a \Rightarrow$$
$$a = \frac{m_2g\text{-}f}{m_1 + m_2}.$$

So far, we have avoided specifying any further details about the friction force. We now do so by first calculating the maximum magnitude of the static friction force, $f_{s,max} = \mu_s N_1$. For the magnitude of the normal force, we already found $N_1 = m_1g$, so we have for the maximum static friction force:

$$f_{s,max} = \mu_s N_1 = \mu_s m_1 g = (0.73)(2.3\text{ kg})\,(9.81\,\text{m/s}^2) = 16$$

We need to compare this value to that of m_2g in the numerator of our equation for the acceleration, $a = (m_2g - f)/(m_1 + m_2)$. If $f_{s,max} \geq m_2g$, then the static friction force will assume a value exactly equal to m_2g, causing the acceleration to be zero. In other words, there will be no motion, because the pull due to block 2 hanging from the rope is not sufficient to overcome the force of static friction between block 1 and its supporting surface. If $f_{s,max} < m_2g$, then there will be positive acceleration, and the

two blocks will start moving. In the present case, because $m_2 g = (1.9\ \text{kg})\left(9.81\,\text{m/s}^2\right) = 18.6\,\text{N}$, the blocks will start moving.

PROBLEM 2

What is the value of the acceleration?

SOLUTION 2

As soon as the static friction force is overcome, kinetic friction takes over. We can then use our equation for the acceleration, $a = (m_2 g - f)/(m_1 + m_2)$, substitute $f = \mu_\text{k} N_1 = \mu_\text{k} m_1 g$, and obtain

$$a = \frac{m_2 g - \mu_\text{k} m_1 g}{m_1 + m_2} = g\left(\frac{m_2 - \mu_\text{k} m_1}{m_1 + m_2}\right).$$

Inserting the numbers, we find

$$a = (9.81\ \text{m/s}^2\left[\frac{(1.9\,\text{kg} - 0.6 \cdot (2.3\ \text{kg})}{(2.3\ \text{kg}) + (1.9\ \text{kg})}\right] = 1.21\,\text{m/s}^2.$$

Self-Test Opportunity 4.4

(a) What is the maximum mass m_2 for which the system of these two blocks does not move? (b) What is the value of the friction force if m_2 is smaller than this value?

SOLVED PROBLEM 4.3 Wedge

A wedge of mass $m = 37.7$ kg is held in place on a fixed plane that is inclined by an angle $\theta = 20.5^\circ$ with respect to the horizontal. A force $F = 309.3\,\text{N}$ in the horizontal direction pushes on the wedge, as shown in Figure 4.24a. The coefficient of kinetic friction between the wedge and the plane is $\mu_k = 0.171$. Assume that the coefficient of static friction is low enough that the net force will move the wedge.

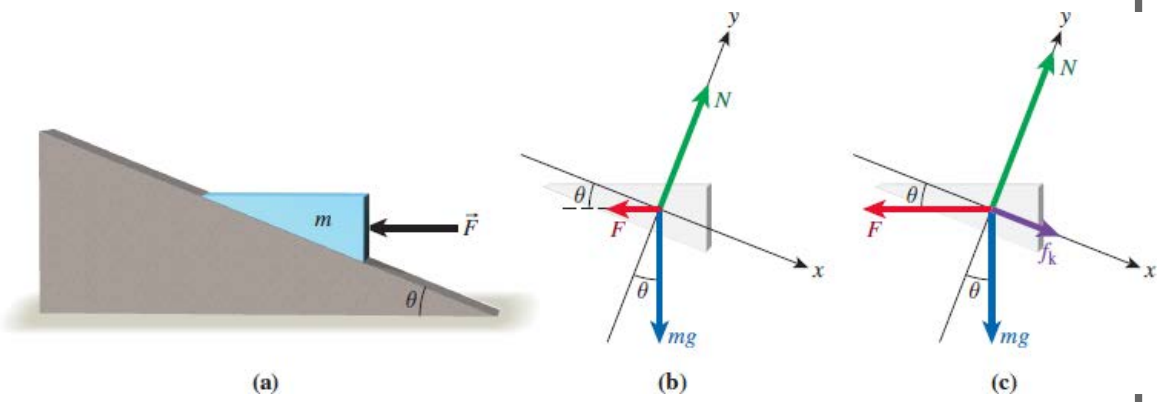

FIGURE 4.24 (a) A wedge-shaped block being pushed on an inclined plane. (b) Free-body diagram of the wedge, including the external force, the force of gravity, and the normal force. (c) Free-body diagram including the external force, the force of gravity, the normal force, and the friction force.

PROBLEM

What is the acceleration of the wedge along the plane when it is released and free to move?

SOLUTION

THINK

We want to know the acceleration a of the wedge of mass m along the plane, which requires us to determine the component of the net force that acts on the wedge parallel to the surface of the inclined plane. Also, we need to find the component of the net force that acts on the wedge perpendicular to the plane, to allow us to determine the force of kinetic friction.

The forces acting on the wedge are gravity, the normal force, the force of kinetic friction f_k, and the external force F. The coefficient of kinetic friction, μ_k, is given, so we can calculate the friction force once we determine the normal force. Before we can continue with our analysis of the forces, we must determine in which direction the wedge will move after it is released as a result of force F. Once we know in which direction the wedge will go, we can determine the direction of the friction force and complete our analysis.

To determine the net force before the wedge begins to move, we need a free-body diagram with just the forces F, N, and mg. Once we determine the direction of motion, we can determine the direction of the friction force, using a second free-body diagram with the friction force added.

SKETCH

A free-body diagram showing the forces acting on the wedge before it is released is presented in Figure 4.24b. We have defined a coordinate system in which the x-axis is parallel to the surface of the inclined plane, with the positive x-direction pointing down the plane. The sum of the forces in the x-direction is

$$mg \sin\theta - F \cos\theta = ma.$$

We need to determine if the mass will move to the right (positive x-direction, or down the plane) or to the left (negative x-direction, or up the plane). We can see from the equation that the quantity $mg \sin\theta - F \cos\theta$ will determine the direction of the motion. With the given numerical values, we have

$$\begin{aligned} mg \sin\theta - F \cos\theta &= (37.7 \text{ kg})\ (9.8 \text{ m/s}^2)(\sin 20.5^\circ) - (30 \\ &= -160.193 \text{ N} \end{aligned}$$

Thus, the mass will move up the plane (to the left, or in the negative x-direction). Now we can redraw the free-body diagram as shown in Figure 4.24c by inserting the arrow for the force of kinetic friction, f_k, pointing down the plane (in the positive x-

direction), because the friction force always opposes the direction of motion.

RESEARCH

Now we can write the components of the forces in the x- and y-directions based on the final free-body diagram. For the x-direction, we have

$$mg\sin\theta - F\cos\theta + f_{\mathrm{k}} = ma. \qquad \textbf{(i)}$$

For the y-direction we have

$$N - mg\cos\theta - F\sin\theta = 0.$$

From this equation, we can get the normal force N that we need to calculate the friction force:

$$f_{\mathrm{k}} = \mu_{\mathrm{k}}N = \mu_{\mathrm{k}}(mg\cos\theta + F\sin\theta). \qquad \textbf{(ii)}$$

SIMPLIFY

Having related all the known and unknown quantities to each other, we can get an expression for the acceleration of the mass using equations i and ii:

$$mg\sin\theta - F\cos\theta + \mu_{\mathrm{k}}(mg\cos\theta + F\sin\theta) = ma.$$

We can rearrange the left side:

$$\begin{aligned} mg\sin\theta - F\cos\theta + \mu_{\mathrm{k}}mg\cos\theta + \mu_{\mathrm{k}}F\sin\theta &= ma \\ (mg + \mu_{\mathrm{k}}F)\sin\theta + (\mu_{\mathrm{k}}mg - F)\cos\theta &= ma, \end{aligned}$$

and then solve for the acceleration:

$$a = \frac{(mg + \mu_k F)\sin\theta + (\mu_k mg - F)\cos\theta}{m}. \quad \textbf{(iii)}$$

CALCULATE

Now we put in the numbers and get a numerical result. The first term in the numerator of equation iii is

$$\left((37.7\,\text{kg})\left(9.81\,\text{m/s}^2\right) + (0.171)(309.3\,\text{N})\right)(\sin 20.5^\circ) = 1$$

Note that we have not rounded this result yet. The second term in the numerator of equation iii is

$$\left((0.171)(37.7\,\text{kg})\left(9.81\,\text{m/s}^2\right) - (309.3\,\text{N})\right)(\cos 20.5^\circ) =$$

Again we have not yet rounded the result. Now we calculate the acceleration using equation iii:

$$a = \frac{(148.042\,\text{N}) + (-230.476\,\text{N})}{37.7\,\text{kg}} = -2.1866\,\text{m/s}^2.$$

ROUND

Because all of the numerical values were initially given with three significant figures, we report our final result as

$$a = -2.19\,\text{m/s}^2.$$

DOUBLE-CHECK

Looking at our answer, we see that the acceleration is negative, which means it is in the negative x-direction. We had determined that the mass would move to the left (up the plane, or in the negative x-direction), which agrees with the sign of the acceleration in our final result. The magnitude of the acceleration

is a fraction of the acceleration of gravity (9.81 m/s^2), which makes physical sense.

SOLVED PROBLEM 4.4 Two Blocks

Two rectangular blocks are stacked on a table as shown in Figure 4.25a. The upper block has a mass of 3.40 kg, and the lower block has a mass of 38.6 kg. The coefficient of kinetic friction between the lower block and the table is 0.260. The coefficient of static friction between the blocks is 0.551. A string is attached to the lower block, and an external force $\vec{F}$ is applied horizontally, pulling on the string as shown.

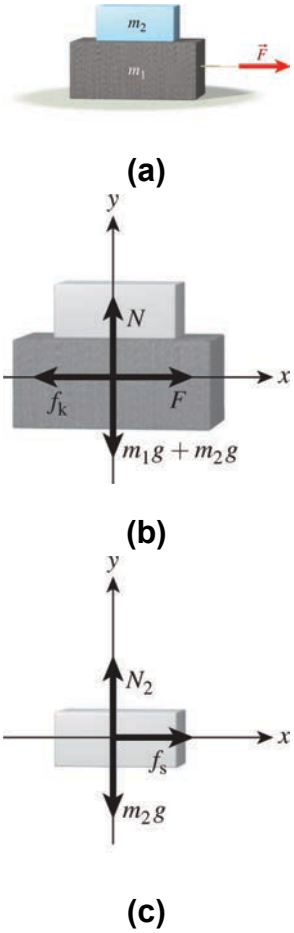

FIGURE 4.25 (a) Two stacked blocks being pulled to the right. (b) Free-body diagram for the two blocks moving together. (c) Free-body diagram for the upper block.

PROBLEM

What is the maximum force that can be applied to the string without having the upper block slide off?

SOLUTION

THINK

To begin this problem, we note that as long as the force of static friction between the two blocks is not overcome, the two blocks will travel together. Thus, if we pull gently on the lower block, the upper block will stay in place on top of it, and the two blocks will slide as one. However, if we pull hard on the lower block, the force of static friction between the blocks will not be sufficient to keep the upper block in place and it will begin to slide off the lower block.

The forces acting in this problem are the external force F pulling on the string, the force of kinetic friction f_k between the lower block and the surface on which the blocks are sliding, the weight $m_1 g$ of the lower block, the weight $m_2 g$ of the upper block, and the force of static friction f_s between the blocks and the normal forces.

SKETCH

We start with a free-body diagram of the two blocks moving together (Figure 4.25b), because we will treat the two blocks as one system for the first part of this analysis. We define the x-direction to be parallel to the surface on which the blocks are sliding and parallel to the external force pulling on the string, with the positive direction to the right, in the direction of the external force. The sum of the forces in the x-direction is

$$F - f_k = (m_1 + m_2)a. \qquad \textbf{(i)}$$

The sum of the forces in the y-direction is

$$N - (m_1 g + m_2 g) = 0. \qquad \textbf{(ii)}$$

Equations i and ii describe the motion of the two blocks together.

Now we need a second free-body diagram to describe the forces acting on the upper block. The forces in the free-body diagram for the upper block (Figure 4.25c) are the normal force N_2 exerted by the lower block, the weight $m_2 g$, and the force of static friction f_s. The sum of the forces in the x-direction is

$$f_s = m_2 a. \tag{iii}$$

The sum of the forces in the y-direction is

$$N_2 - m_2 g = 0. \tag{iv}$$

RESEARCH

The maximum value of the force of static friction between the upper and lower blocks is given by

$$f_s = \mu_s N_2 = \mu_s (m_2 g).$$

where we have used equations iii and iv. Thus, the maximum acceleration that the upper block can have without sliding is

$$a_{\max} = \frac{f_s}{m_2} = \frac{\mu_s m_2 g}{m_2} = \mu_s g. \tag{v}$$

This maximum acceleration for the upper block is also the maximum acceleration for both blocks together. From equation ii, we get the normal force between the lower block and the sliding surface:

$$N = m_1 g + m_2 g. \tag{vi}$$

The force of kinetic friction between the lower block and the sliding surface is then

$$f_k = \mu_k (m_1 g + m_2 g). \tag{vii}$$

SIMPLIFY

We can now relate the maximum acceleration to the maximum force, $F_{\text{max},}$ that can be exerted without the upper block sliding off, using equations v and vii:

$$F_{\text{max}} = \mu_{\text{k}}(m_1 g + m_2 g) = (m_1 + m_2)\mu_{\text{s}} g.$$

We solve this for the maximum force to obtain

$$F_{\text{max}} = \mu_{\text{k}}(m_1 g + m_2 g) = (m_1 + m_2)\mu_{\text{s}} g = g(m_1 + m_2)(\mu$$

CALCULATE

Putting in the given numerical values, we get

$$F_{\text{max}} = (9.81\,\text{m/s}^2) = (38.6\ \text{kg} + 3.40\ \ \text{kg}\,)(0.260 + 0.551)$$

ROUND

All of the numerical values were given to three significant figures, so we report our answer as

$$F_{\text{max}} = 334\,\text{N}.$$

DOUBLE-CHECK

The answer is a positive value, implying a force to the right, which agrees with the free-body diagram in Figure 4.25b.

The maximum acceleration is

$$a_{\text{max}} = \mu_{\text{s}} g = (0.551)\left(9.81\,\text{m/s}^2\right) = 5.41\,\text{m/s}^2,$$

which is a fraction of the acceleration due to gravity, which seems reasonable. If there were no friction between the lower block and

the surface on which it slides, the force required to accelerate both blocks would be

$$F = (m_1 + m_2)a_{\text{max}} = (38.6\ \text{kg} + 3.40\ \text{kg})\left(5.41\ \text{m/s}^2\right) =$$

Thus, our answer of 334 N for the maximum force seems reasonable because it is higher than the force calculated when there is no friction.

EXAMPLE 4.9 Pulling a Sled

Suppose you are pulling a sled across a level snow-covered surface by exerting constant force on a rope, at an angle θ relative to the ground.

PROBLEM 1

If the sled, including its load, has a mass of 15.3 kg, the coefficients of friction between the sled and the snow are $\mu_s = 0.076$ and $\mu_k = 0.070$, and you pull with a force of 25.3 N on the rope at an angle of 24.5° relative to the horizontal ground, what is the sled's acceleration?

SOLUTION 1

Figure 4.26 shows the free-body diagram for the sled, with all the forces acting on it. The directions of the force vectors are correct, but the magnitudes are not necessarily drawn to scale. The acceleration of the sled will, if it occurs at all, be directed along the horizontal, in the x-direction. In terms of components, Newton's Second Law gives:

$$x\text{- component: } ma = T\cos\theta - f$$

and

$$y\text{- component: } 0 = T\sin\theta - mg + N.$$

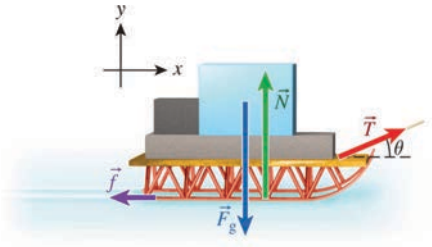

FIGURE 4.26 Free-body diagram of the sled and its load.

For the friction force, we will use the form $f = \mu N$ for now, without specifying whether it is kinetic or static friction, but in the end we will have to return to this point. The normal force can be calculated from the above equation for the y-component and then substituted into the equation for the x-component:

$$\begin{aligned} N &= mg - T\sin\theta \\ ma &= T\cos\theta - \mu(mg - T\sin\theta) \Rightarrow \\ a &= \frac{T}{m}(\cos\theta + \mu\sin\theta) - \mu g. \end{aligned}$$

We see that the normal force is less than the weight of the sled, because the force pulling on the rope has an upward y-component. The vertical component of the force pulling on the rope also contributes to the acceleration of the sled since it affects the normal force and hence the horizontal frictional force.

When putting in the numbers, we first use the value of the coefficient of static friction to see if enough force is applied by pulling on the rope to generate a positive acceleration. If the resulting value for a turns out to be negative, this means that there is not enough pulling force to overcome the static friction force. With the given value of $\mu_s(0.076)$, we obtain

$$a' = \frac{25.3\,\mathrm{N}}{15.3\,\mathrm{kg}}(\cos 24.5^\circ + 0.076\sin 24.5^\circ) - 0.076\left(9.81\ \mathrm{m/s^2}\right.$$

Because this calculation results in a positive value for a', we know that the force is strong enough to overcome the friction force. We now use the given value for the coefficient of kinetic friction to calculate the actual acceleration of the sled:

$$a = \frac{25.3\,\mathrm{N}}{15.3\,\mathrm{kg}}(\cos 24.5^\circ + 0.076\sin 24.5^\circ) - 0.070\left(9.81\ \mathrm{m/s^2}\right.$$

PROBLEM 2

What angle of the rope with the horizontal will produce the maximum acceleration of the sled for the given value of the magnitude of the pulling force, T? What is that maximum value of a?

SOLUTION 2

In calculus, to find the extremum of a function, we take the first derivative and find the value of the independent variable for which that derivative is zero:

$$\frac{d}{d\theta}a = \frac{d}{d\theta}\left(\frac{T}{m}(\cos\theta + \mu\sin\theta) - \mu g\right) = \frac{T}{m}(-\sin\theta + \mu$$

Searching for the root of this equation results in

$$\left.\frac{da}{d\theta}\right|_{\theta=\theta_{\max}} = \frac{T}{m}(-\sin\theta_{\max} + \mu\cos\theta_{\max}) = 0 \Rightarrow$$
$$\Rightarrow \sin\theta_{\max} = \mu\cos\theta_{\max} \Rightarrow$$
$$\theta_{\max} = \tan^{-1}\mu.$$

Inserting the given value for the coefficient of kinetic friction, 0.070, into this equation results in $\theta_{\max} = 4.0^\circ$. This means that the rope should be oriented almost horizontally. The resulting value of the acceleration can be obtained by inserting the numbers into the equation for a we used in Solution 1:

$$a_{\max} \equiv a(\theta_{\max}) = 0.97\,\mathrm{m/s^2}.$$

Note: A zero first derivative is only a necessary condition for a maximum, not a sufficient one. You can convince yourself that we have indeed found the maximum by first realizing that we obtained only one root of the first derivative, meaning that the function $a(\theta)$ has only one extremum. Also, because the value of the acceleration we calculated at this point is bigger than the value we previously obtained for 24.5°, we are assured that our single extremum is indeed a maximum. Alternatively, we could have taken the second derivative and found that it is negative at

the point $\theta_{max} = 4.0^{\circ}$; then, we could have compared the value of the acceleration obtained at that point with those at θ = 0° and θ= 90°.

Self-Test Opportunity 4.5

What is the value of the second derivative if the angle of the sled's rope relative to the ground is 4.0°?

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- The net force on an object is the vector sum of the forces acting on the object: $\overrightarrow{F}_{\text{net}} = \sum_{i=1}^{n} \overrightarrow{F}_i$.
- Mass is an intrinsic quality of an object that quantifies both the object's ability to resist acceleration and the gravitational force on the object.
- A free-body diagram is an abstraction showing all forces acting on an isolated object.
- Newton's three laws are as follows:

  Newton's First Law. In the absence of a net force on an object, the object will remain at rest if it was at rest. If it was moving, it will remain in motion in a straight line with the same velocity.

  Newton's Second Law. If a net external force, $\overrightarrow{F}_{\text{net}}$, acts on an object with mass m, the force will cause an acceleration, $\overrightarrow{a}$, in the same direction as the force: $\overrightarrow{F}_{\text{net}} = m\overrightarrow{a}$.

  Newton's Third Law. The forces that two interacting objects exert on each other are always exactly equal in magnitude and opposite in direction: $\overrightarrow{F}_{1\to 2} = -\overrightarrow{F}_{2\to 1}$.
- Two types of friction occur: static and kinetic friction. Both types of friction are proportional to the normal force, N.

  Static friction describes the force of friction between an object at rest on a surface in terms of the coefficient of static friction, μ_s. The static friction force, f_s, opposes a force trying to move an object and has a maximum value, $f_{s,\max}$, such that $f_s \leq \mu_s N = f_{s,\max}$.

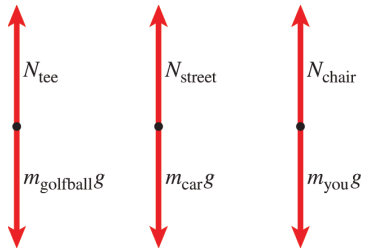
  Kinetic friction describes the force of friction between a moving object and a surface in terms of the coefficient of

kinetic friction, μ_{k}. Kinetic friction is given by $f_{\mathrm{k}} = \mu_{\mathrm{k}} N$
.

In general, $\mu_{\mathrm{s}} > \mu_{\mathrm{k}}$.

ANSWERS TO SELF-TEST OPPORTUNITIES

4.1



4.2 We have found for the acceleration of the two masses the general result $a = g(m_1 - m_2)(m_1 + m_2)$. If m_1 approaches infinity, we can neglect m_2 compared to m_1. This means that the numerator and denominator of the fraction both approach 1, and we have $a = g$. For $m_1 = 0$, we have $a = -g$, and for $m_1 = m_2$, we have a = 0.

4.3 Using $T = m_2(g + a)$ and inserting the value for the acceleration, $a = g\left(\frac{m_1 - m_2}{m_1 + m_2}\right)$, we find

$$T = m_2(g + a) = m_2\left(g + g\frac{m_1 - m_2}{m_1 + m_2}\right) = m_2 g\left(\frac{m_1 + m_2}{m_1 + m_2} + \right.$$
$$= 2g\frac{m_1 m_2}{m_1 + m_2}.$$

4.4 (a) From $a = (m_2 g - f)/(m_1 + m_2)$ and the condition that $f \leq f_{s,\max} = \mu_s m_1 g$, we see that the largest value m_2 can have is $m_2 = f_{s,\max}/g = \mu_s m_1$. (b) For $m_2 < \mu_s m_1$, nothing moves; so the acceleration has to be zero, which means that the numerator of the expression for the acceleration must be zero. Therefore, in this case, $f = m_2 g$.

4.5 Taking the second derivative, we find

$$\frac{d^2a}{d\theta^2} = \frac{d}{d\theta}\left(\frac{T}{m}(-\sin\theta + \mu\cos\theta)\right) = \frac{T}{m}(-\cos\theta - \mu\sin\theta) =$$

Since we have found $a(\theta_{max})$ = 0.97 m/s², the value of the second derivative at 4.00° is −0.97 m/s², which is smaller than zero, confirming that our extremum is indeed a maximum.

PROBLEM-SOLVING GUIDELINES: NEWTON'S LAWS

Analyzing a situation in terms of forces and motion is a vital skill in physics. One of the most important techniques is the proper application of Newton's laws. The following guidelines can help you solve mechanics problems in terms of Newton's three laws. These are part of the seven-step strategy for solving all types of physics problems and are most relevant to the Sketch, Think, and Research steps.

1. An overall sketch can help you visualize the situation and identify the concepts involved, but you also need a separate free-body diagram for each object to identify which forces act on that particular object and no others. Drawing correct free-body diagrams is the key to solving all problems in mechanics, whether they involve static (nonmoving) objects or kinetic (moving) ones. Remember that the $m\vec{a}$ from Newton's Second Law should not be included as a force in any free-body diagram.

2. Choosing the coordinate system is important—often the choice of coordinate system makes the difference between very simple equations and very difficult ones. Placing an axis along the same direction as an object's acceleration, if there is any, is often very helpful. In a statics problem, orienting an axis along a surface, whether horizontal or inclined, is often useful. Choosing the most advantageous coordinate system is an acquired skill gained through experience as you work many problems.

3. Once you have chosen your coordinate directions, determine whether the situation involves acceleration in either direction. If no acceleration occurs in the y-direction, for example, then Newton's First Law applies in that direction, and the sum of forces (the net force) equals zero. If acceleration does occur in a given direction, for example, the x-direction, then Newton's Second Law

applies in that direction, and the net force equals the object's mass times its acceleration.

4. When you decompose a force vector into components along the coordinate directions, be careful about which direction involves the sine of a given angle and which direction involves the cosine. Do not generalize from past problems and think that all components in the x-direction involve the cosine; you will find problems where the x-component involves the sine. Rely instead on clear definitions of angles and coordinate directions and the geometry of the given situation. Often the same angle appears at different points and between different lines in a problem. This usually results in similar triangles, often involving right angles. If you create a sketch of a problem with a general angle θ, try to use an angle that is not close to 45°, because it is hard to distinguish between such an angle and its complement in your sketch.

5. Always check your final answer. Do the units make sense? Are the magnitudes reasonable? If you change a variable to approach some limiting value, does your answer make a valid prediction about what happens? Sometimes you can estimate the answer to a problem by using order-of-magnitude approximations, as discussed in Chapter 1; such an estimate can often reveal whether you made an arithmetical mistake or wrote down an incorrect formula.

6. The friction force always opposes the direction of motion and acts parallel to the contact surface; the static friction force opposes the direction in which the object would move, if the friction force were not present. Note that the kinetic friction force is *equal* to the product of the coefficient of friction and the normal force, whereas the static friction force is *less than or equal* to that product.

MULTIPLE-CHOICE QUESTIONS

4.1 A car of mass M travels in a straight line at constant speed along a level road with a coefficient of friction between the tires and the road of μ and a drag force of D. The magnitude of the net force on the car is

a) μMg.

b) $\mu Mg + D$.

c) $\sqrt{(\mu Mg)^2 + D^2}$.

d) zero.

4.2 A person stands on the surface of the Earth. The mass of the person is m, and the mass of the Earth is M. The person jumps upward, reaching a maximum height h above the Earth. When the person is at this height h, the magnitude of the force exerted on the Earth by the person is

a) mg.

b) Mg.

c) M^2g/m.

d) m^2g/M.

e) zero.

4.3 Leonardo da Vinci discovered that the magnitude of the friction force is simply proportional to the magnitude of the normal force only; that is, the friction force does not depend on the width or length of the contact area. Thus, the main reason to use wide tires on a race car is that they

a) look cool.

b) have more apparent contact area.

c) cost more.

d) can be made of softer materials.

4.4 The Tornado is a carnival ride that consists of a hollow vertical cylinder that rotates rapidly about its vertical axis. As the Tornado rotates, the riders are pressed against the inside wall of the cylinder by the rotation, and the floor of the cylinder drops away. The force that points upward, preventing the riders from falling downward, is

a) friction force.

b) a normal force.

c) gravity.

d) a tension force.

4.5 When a bus makes a sudden stop, passengers tend to jerk forward. Which of Newton's laws can explain this?

a) Newton's First Law

b) Newton's Second Law

c) Newton's Third Law

d) It cannot be explained by Newton's laws.

4.6 Only two forces, $\overrightarrow{F_1}$ and $\overrightarrow{F_2}$ are acting on a block. Which of the following can be the magnitude of the net force, F, acting on the block (indicate all possibilities)?

a) $F > F_1 + F_2$

b) $F = F_1 + F_2$

c) $F < F_1 + F_2$

d) none of the above

4.7 Which of the following observations about the friction force is (are) incorrect?

a) The magnitude of the kinetic friction force is always proportional to the normal force.

b) The magnitude of the static friction force is always proportional to the normal force.

c) The magnitude of the static friction force is always proportional to the external applied force.

d) The direction of the kinetic friction force is always opposite the direction of the relative motion of the object with respect to the surface the object moves on.

e) The direction of the static friction force is always opposite that of the impending motion of the object relative to the surface it rests on.

f) All of the above are correct.

4.8 A horizontal force equal to the object's weight is applied to an object resting on a table. What is the acceleration of the moving object when the coefficient of kinetic friction between the object and floor is 1 (assuming the object is moving in the direction of the applied force)?

a) zero

b) $1\,\mathrm{m/s^2}$

c) Not enough information is given to find the acceleration.

4.9 Two blocks of equal mass are connected by a massless horizontal rope and resting on a frictionless table. When one of the blocks is

pulled away by a horizontal external force F, what is the ratio of the net forces acting on the blocks?

a) 1:1

b) 1:1.41

c) 1:2

d) none of the above

4.10 If a cart sits motionless on level ground, there are no forces acting on the cart.

a) true

b) false

c) maybe

4.11 An object whose mass is 0.092 kg is initially at rest and then attains a speed of 75.0 m/s in 0.028 s. What average net force acted on the object during this time interval?

a) $1.2 \cdot 10^2$ N

b) $2.5 \cdot 10^2$ N

c) $2.8 \cdot 10^2$ N

d) $4.9 \cdot 10^2$ N

4.12 You push a large crate across the floor at constant speed, exerting a horizontal force *F* on the crate. There is friction between the floor and the crate. The force of friction has a magnitude that is

a) zero.

b) *F*.

c) greater than *F*.

d) less than *F*.

e) impossible to quantify without further information.

4.13 Which of the following fundamental forces are not apparent to us in our everyday lives?

a) gravitational force

b) electromagnetic force

c) strong nuclear force

d) weak nuclear force

4.14 An SUV of mass 3250 kg has a head-on collision with a 1250-kg subcompact. Identify all the statements that are incorrect.

a) The SUV exerts a larger force on the subcompact than the subcompact exerts on the SUV.

b) The subcompact exerts a larger force on the SUV than the SUV exerts on the subcompact.

c) The subcompact experiences a larger acceleration than the SUV.

d) The SUV experiences a larger acceleration that the subcompact.

4.15 Which one of the following statements is correct?

a) The gravitational force on an object is always directed upward.

b) The gravitational force on an object is always directed downward.

c) The gravitational force on an object depends on the vertical speed of the object.

d) The gravitational force on an object depends on the horizontal speed of the object.

4.16 A normal force is a contact force that acts at the surface between two objects. Which of the following statements concerning the normal force is not correct?

a) The normal force is always equal to the force of gravity.

b) The normal force is just large enough to keep the two objects from penetrating each other.

c) The normal force is not necessarily equal to the force of gravity.

d) The normal force is perpendicular to the plane of the contact surface between the two objects.

CONCEPTUAL QUESTIONS

4.17 You are at the shoe store to buy a pair of basketball shoes that have the greatest traction on a specific type of hardwood. To determine the coefficient of static friction, μ, you place each shoe on a plank of the wood and tilt the plank to an angle θ, at which the shoe just starts to slide. Obtain an expression for μ as a function of θ.

4.18 A heavy wooden ball is hanging from a ceiling by a piece of string that is attached to the ceiling and to the top of the ball. A similar piece of string is attached to the bottom of the ball. If the loose end of the lower string is pulled down sharply, which is the string that is most likely to break?

4.19 A car pulls a trailer down the highway. Let F_{t} be the magnitude of the force on the trailer due to the car, and let F_{c} be the magnitude of the force on the car due to the trailer. If the car and trailer are moving at a constant velocity across level ground, then $F_{\mathrm{t}} = F_{\mathrm{c}}$. If the car and trailer are accelerating up a hill, what is the relationship between the two forces?

4.20 A car accelerates down a level highway. What is the force in the direction of motion that accelerates the car?

4.21 If the forces that two interacting objects exert on each other are always exactly equal in magnitude and opposite in direction, how is it possible for an object to accelerate?

4.22 True or false: A physics book on a table will not move at all if and only if the net force is zero.

4.23 A mass slides on a ramp that is at an angle of θ above the horizontal. The coefficient of friction between the mass and the ramp is μ.

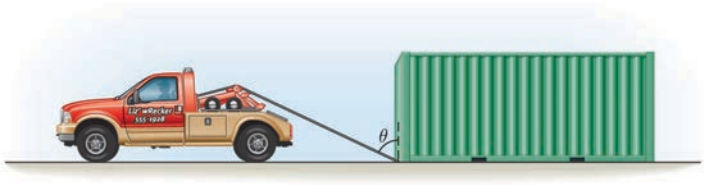
a) Find an expression for the magnitude and direction of the acceleration of the mass as it slides up the ramp.

b) Repeat part (a) to find an expression for the magnitude and direction of the acceleration of the mass as it slides down the ramp.

4.24 A shipping crate that weighs 340 N is initially stationary on a loading dock. A forklift arrives and lifts the crate with an upward force of 500 N, accelerating the crate upward. What is the magnitude of the force due to gravity acting on the shipping crate while it is accelerating upward?

4.25 A block is sliding on a (near) frictionless slope with an incline of 30.0°. Which force is greater in magnitude, the net force acting on the block or the normal force acting on the block?

4.26 A tow truck of mass M is using a cable to pull a shipping container of mass m across a horizontal surface as shown in the figure. The cable is attached to the container at the front bottom corner and makes an angle θ with the vertical as shown. The coefficient of kinetic friction between the surface and the crate is μ.



a) Draw a free-body diagram for the container.

b) Assuming that the truck pulls the container at a constant speed, write an equation for the magnitude T of the string tension in the cable.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 4.2

4.27 The gravitational acceleration on the Moon is a sixth of that on Earth. The weight of an apple is 1.00 N on Earth.

a) What is the weight of the apple on the Moon?

b) What is the mass of the apple?

Section 4.4

4.28 A 423.5-N force accelerates a go-cart and its driver from 10.4 m/s to 17.9 m/s in 5.00 s. What is the mass of the go-cart plus driver?

4.29 You have just joined an exclusive health club, located on the top floor of a skyscraper. You reach the facility by using an express elevator. The elevator has a precision scale installed so that members can weigh themselves before and after their workouts. A member steps into the elevator and gets on the scale before the elevator doors close. The scale shows a weight of 183.7 lb. Then the elevator accelerates upward with an acceleration of 2.43 m/s^2, while the member is still standing on the scale. What is the weight shown by the scale's display while the elevator is accelerating?

4.30 An elevator cabin has a mass of 358.1 kg, and the combined mass of the people inside the cabin is 169.2 kg. The cabin is pulled upward by a cable, with a constant acceleration of 4.11 m/s^2. What is the tension in the cable?

4.31 An elevator cabin has a mass of 363.7 kg, and the combined mass of the people inside the cabin is 177.0 kg. The cabin is pulled upward by a cable, in which there is a tension force of 7638 N. What is the acceleration of the elevator?

4.32 Two blocks are in contact on a frictionless, horizontal tabletop.

An external force, F, is applied to block 1, and the two blocks are moving with a constant acceleration of 2.45 m/s^2. Use $M_1 = 3.20$ kg and $M_2 = 5.70$ kg.

a) What is the magnitude, F, of the applied force?

b) What is the contact force between the blocks?

c) What is the net force acting on block 1?

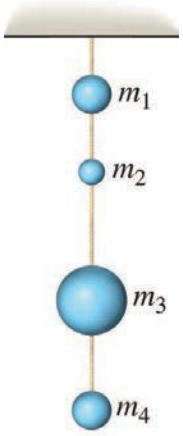
·**4.33** The density (mass per unit volume) of ice is 917 kg/m^3, and the density of seawater is 1024 kg/m^3. Only 10.45% of the volume of

an iceberg is above the water's surface. If the volume of a particular iceberg that is above water is 4205.3 m^3, what is the magnitude of the force that the seawater exerts on this iceberg?

·**4.34** In a physics laboratory class, three massless ropes are tied together at a point. A pulling force is applied along each rope: $F_1 = 150.\text{N}$ at 60.0°, $F_2 = 200.\text{N}$ at 100.°, $F_3 = 100.\text{N}$ at 190.°. What is the magnitude of a fourth force and the angle at which it acts to keep the point at the center of the system stationary? (All angles are measured from the positive *x*-axis.)

Section 4.5

4.35 Four weights, of masses $m_1 = 6.50$ kg, $m_2 = 3.80$ kg, $m_3 = 10.70$ kg, and $m_4 = 4.20$ kg, are hanging from a ceiling as shown in the figure. They are connected with ropes. What is the tension in the rope connecting masses m_1 and m_2?



4.36 A hanging mass, $M_1 = 0.500$ kg, is attached by a light string that runs over a frictionless pulley to a mass $M_2 = 1.50$ kg that is initially at rest on a frictionless table. Find the magnitude of the acceleration, a, of M_2.

·**4.37** A hanging mass, $M_1 = 0.500$ kg, is attached by a light string that runs over a frictionless pulley to the front of a mass $M_2 = 1.50$ kg that is initially at rest on a frictionless table. A third mass $M_3 = 2.50$ kg, which is also initially at rest on the same frictionless table, is attached to the back of M_2 by a light string.

a) Find the magnitude of the acceleration, a, of mass M_3.

b) Find the tension in the string between masses M_1 and M_2.

·**4.38** A hanging mass, $M_1 = 0.400$ kg, is attached by a light string that runs over a frictionless pulley to a mass $M_2 = 1.20$ kg that is initially at rest on a frictionless ramp. The ramp is at an angle of $\theta = 30.0^\circ$ above the horizontal, and the pulley is at the top of the ramp. Find the magnitude and direction of the acceleration, a_2, of M_2.

·**4.39** A force table is a circular table with a small ring that is to be balanced in the center of the table. The ring is attached to three hanging masses by strings of negligible mass that pass over

frictionless pulleys mounted on the edge of the table. The magnitude and direction of each of the three horizontal forces acting on the ring can be adjusted by changing the amount of each hanging mass and the position of each pulley, respectively. Given a mass $m_1 = 0.0400\,\text{kg}$ pulling in the positive x-direction and a mass $m_2 = 0.0300\,\text{kg}$ pulling in the positive y-direction, find the mass (m_3) and the angle (θ, counterclockwise from the positive x-axis) that will balance the ring in the center of the table.

·**4.40** A monkey is sitting on a wood plate attached to a rope whose other end is passed over a tree branch, as shown in the figure. The monkey holds the rope and tries to pull it down. The combined mass of the monkey and the wood plate is 100. kg. Assume that you can neglect the friction between the rope and the branch.

a) What is the minimum force the monkey has to apply to lift itself and the plate off the ground?

b) What applied force is needed to move the monkey with an upward acceleration of 2.45 m/s^2?

c) Explain how the answers would change if a second monkey on the ground pulled on the rope instead.

Section 4.6

4.41 A bosun's chair is a device used by a boatswain to lift himself to the top of the mainsail of a ship. A simplified device consists of a chair, a rope of negligible mass, and a frictionless pulley attached to the top of the mainsail. The rope goes over the pulley, with one end attached to the chair, and the boatswain pulls on the other end, lifting himself upward. The chair and boatswain have a total mass M = 90.0 kg.

a) If the boatswain is pulling himself up at a constant speed, with what magnitude of force must he pull on the rope?

b) If, instead, the boatswain moves in a jerky fashion, accelerating upward with a maximum acceleration of magnitude a = 2.00 m/s^2, with what maximum magnitude of force must he pull on the rope?

4.42 A granite block of mass 3311 kg is suspended from a pulley system as shown in the figure. The rope is wound around the pulleys six times. What is the force with which you would have to pull on the rope to hold the granite block in equilibrium?

4.43 Arriving on a newly discovered planet, the captain of a spaceship performed the following experiment to calculate the gravitational acceleration for the planet: She placed masses of 100.0

g and 200.0 g on an Atwood device made of massless string and a frictionless pulley and measured that it took 1.52 s for each mass to travel 1.00 m from rest.

a) What is the gravitational acceleration for the planet?

b) What is the tension in the string?

·**4.44** A store sign of mass 4.25 kg is hung by two wires that each make an angle of $\theta = 42.4^\circ$ with the ceiling. What is the tension in each wire?

·**4.45** A crate of oranges slides down an inclined plane without friction. If it is released from rest and reaches a speed of 5.832 m/s after sliding a distance of 2.29 m, what is the angle of inclination of the plane with respect to the horizontal?

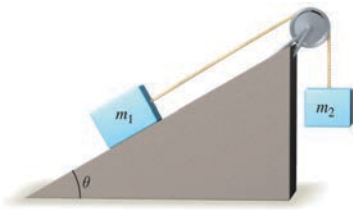
·**4.46** A load of bricks of mass $M = 200.0$ kg is attached to a crane by a cable of negligible mass and length $L = 3.00$ m. Initially, when the cable hangs vertically downward, the bricks are a horizontal distance $D = 1.50$ m from the wall where the bricks are to be placed. What is the magnitude of the horizontal force that must be applied to the load of bricks (without moving the crane) so that the bricks will rest directly above the wall?

·**4.47** A large ice block of mass $M = 80.0$ kg is held stationary on a frictionless ramp. The ramp is at an angle of $\theta = 36.9^\circ$ above the horizontal.

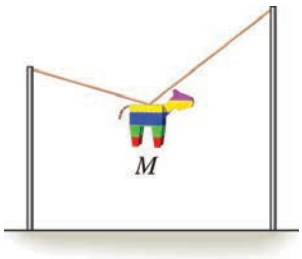
a) If the ice block is held in place by a tangential force along the surface of the ramp (at angle θ above the horizontal), find the magnitude of this force.

b) If, instead, the ice block is held in place by a horizontal force, directed horizontally toward the center of the ice block, find the magnitude of this force.

·**4.48** A mass, $m_1 = 20.0$ kg, on a frictionless ramp is attached to a light string. The string passes over a frictionless pulley and is attached to a hanging mass, m_2. The ramp is at an angle of $\theta = 30.0^\circ$ above the horizontal. The mass m_1 moves up the ramp uniformly (at constant speed). Find the value of m_2.



·**4.49** A piñata of mass M = 8.00 kg is attached to a rope of negligible mass that is strung between the tops of two vertical poles. The horizontal distance between the poles is D = 2.00 m, and the top of the right pole is a vertical distance h = 0.500 m higher than the top of the left pole. The piñata is attached to the rope at a horizontal position halfway between the two poles and at a vertical distance s = 1.00 m below the top of the left pole. Find the tension in each part of the rope due to the weight of the piñata.



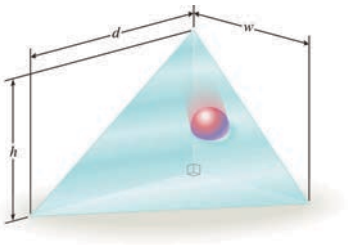
··**4.50** A piñata of mass M = 12.0 kg hangs on a rope of negligible mass that is strung between the tops of two vertical poles. The horizontal distance between the poles is D = 2.00 m, the top of the right pole is a vertical distance h = 0.500 m higher than the top of the left pole, and the total length of the rope between the poles is L = 3.00 m. The piñata is attached to a ring, with the rope passing through the center of the ring. The ring is frictionless, so that it can slide freely along the rope until the piñata comes to a point of static equilibrium.

a) Determine the distance from the top of the left (lower) pole to the ring when the piñata is in static equilibrium.

b) What is the tension in the rope when the piñata is at this point of static equilibrium?

••4.51 Three objects with masses $m_1 = 36.5$ kg, $m_2 = 19.2$ kg, and $m_3 = 12.5$ kg are hanging from ropes that run over pulleys. What is the acceleration of m_1?

••4.52 A rectangular block of width w = 116.5 cm, depth d = 164.8 cm, and height h = 105.1 cm is cut diagonally from one upper corner to the opposing lower corners so that a triangular surface is generated, as shown in the figure. A paperweight of mass m = 16.93 kg is sliding down the incline without friction. What is the magnitude of the acceleration that the paperweight experiences?



••4.53 A large cubical block of ice of mass M = 64.0 kg and sides of length L = 0.400 m is held stationary on a frictionless ramp. The ramp is at an angle of $\theta = 26.0^\circ$ above the horizontal. The ice cube is held in place by a rope of negligible mass and length l = 1.60 m. The rope is attached to the surface of the ramp and to the upper edge of the ice cube, a distance L above the surface of the ramp. Find the tension in the rope.

••**4.54** A bowling ball of mass $M_1 = 6.00\,\text{kg}$ is initially at rest on the sloped side of a wedge of mass $M_2 = 9.00\,\text{kg}$ that is on a frictionless horizontal floor. The side of the wedge is sloped at an angle of $\theta = 36.9^\circ$ above the horizontal.

a) What is the magnitude of the horizontal force that should be exerted on the bowling ball to keep it at a constant height on the slope?

b) What is the magnitude of the acceleration of the wedge, if no external force is applied?

Section 4.7

4.55 A skydiver of mass 82.3 kg (including outfit and equipment) floats downward suspended from her parachute, having reached terminal speed. The drag coefficient is 0.533, and the area of her parachute is 20.11 m^2. The density of air is 1.14 kg/m^3. What is the air's drag force on her?

4.56 The elapsed time for a top fuel dragster to start from rest and travel in a straight line a distance of $\frac{1}{4}$ mile (402 m) is 4.441 s. Find the minimum coefficient of friction between the tires and the track needed to achieve this result. (Note that the minimum coefficient of friction is found from the simplifying assumption that the dragster accelerates with constant acceleration. For this problem we neglect the downward forces from spoilers and the exhaust pipes.)

4.57 An engine block of mass M is on the flatbed of a pickup truck that is traveling in a straight line down a level road with an initial speed of 30.0 m/s. The coefficient of static friction between the block and the bed is $\mu_s = 0.540$. Find the minimum distance in which the truck can come to a stop without the engine block sliding toward the cab.

·**4.58** A box of books is initially at rest a distance D = 0.540 m from the end of a wooden board. The coefficient of static friction between the box and the board is $\mu_s = 0.320$, and the coefficient of kinetic friction is $\mu_k = 0.250$. The angle of the board is increased slowly, until the box just begins to slide; then the board is held at this angle. Find the speed of the box as it reaches the end of the board.

·**4.59** A block of mass $M_1 = 0.640$ kg is initially at rest on a cart of mass $M_2 = 0.320$ kg with the cart initially at rest on a level air track. The coefficient of static friction between the block and the cart is $\mu_s = 0.620$, but there is essentially no friction between the air track and the cart. The cart is accelerated by a force of magnitude F parallel to the air track. Find the maximum value of F that allows the block to accelerate with the cart, without sliding on top of the cart.

Section 4.8

4.60 Coffee filters behave like small parachutes, with a drag force that is proportional to the velocity squared, $f_{\text{drag}} = Kv_2$. A single coffee filter, when dropped from a height of 2.00 m, reaches the ground in a time of 3.00 s. When a second coffee filter is nestled within the first, the drag coefficient remains the same, but the weight is doubled. Find the time for the combined filters to reach the ground. (Neglect the brief period when the filters are accelerating up to their terminal speed.)

4.61 Your refrigerator has a mass of 112.2 kg, including the food in it. It is standing in the middle of your kitchen, and you need to move it. The coefficients of static and kinetic friction between the fridge and the tile floor are 0.460 and 0.370, respectively. What is the magnitude of the force of friction acting on the fridge, if you push against it horizontally with a force of each magnitude?

a) 300.0 N

b) 500.0 N

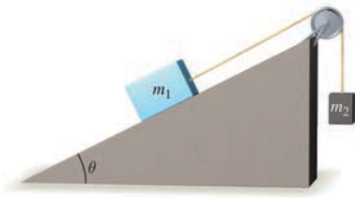
c) 700.0 N

·**4.62** On the bunny hill at a ski resort, a towrope pulls the skiers up the hill with constant speed of 1.74 m/s. The slope of the hill is 12.4° with respect to the horizontal. A child is being pulled up the hill. The coefficients of static and kinetic friction between the child's skis and the snow are 0.152 and 0.104, respectively, and the child's mass is 62.4 kg, including clothing and equipment. What is the force with which the towrope has to pull on the child?

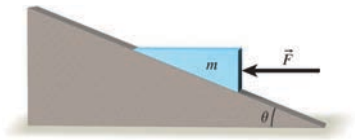
·**4.63** A skier starts with a speed of 2.00 m/s and skis straight down a slope with an angle of 15.0° relative to the horizontal. The coefficient of kinetic friction between her skis and the snow is 0.100. What is her speed after 10.0 s?

··**4.64** A block of mass $m_1 = 21.9$ kg is at rest on a plane inclined at $\theta = 30.0^\circ$ above the horizontal. The block is connected via a rope and massless pulley system to another block of mass $m_2 = 25.1$ kg, as shown in the figure. The coefficients of static and kinetic friction between block 1 and the inclined plane are $\mu_s = 0.109$ and $\mu_k = 0.086$, respectively. If the blocks are released from rest, what is the displacement of block 2 in the vertical direction after 1.51 s? Use

positive numbers for the upward direction and negative numbers for the downward direction.



••**4.65** A wedge of mass m = 36.1 kg is located on a plane that is inclined by an angle $\theta = 21.3^\circ$ with respect to the horizontal. A force F = 302.3 N in the horizontal direction pushes on the wedge, as shown in the figure. The coefficient of kinetic friction between the wedge and the plane is 0.159. What is the acceleration of the wedge along the plane?

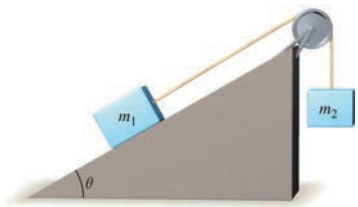


••**4.66** A chair of mass M rests on a level floor, with a coefficient of static friction $\mu_s = 0.560$ between the chair and the floor. A person wishes to push the chair across the floor. He pushes downward on the chair with a force F at an angle θ relative to the horizontal. What is the minimum value of θ for which the chair will not start to move across the floor, no matter how large F gets?

••**4.67** As shown in the figure, blocks of masses $m_1 = 250.0$ g and $m_2 = 500.0$ g are attached by a massless string over a frictionless and massless pulley. The coefficients of static and kinetic friction between the block and inclined plane are 0.250 and 0.123, respectively. The angle of the incline is $\theta = 30.0^\circ$, and the blocks are at rest initially.

a) In which direction do the blocks move?

b) What is the acceleration of the blocks?



••**4.68** A block of mass M = 500.0 g sits on a horizontal tabletop. The coefficients of static and kinetic friction are 0.530 and 0.410, respectively, at the contact surface between table and block. The block is pushed on with a 10.0 N external force at an angle θ with the horizontal.

a) What angle will lead to the maximum acceleration of the block for a given pushing force?

b) What is the maximum acceleration?

Additional Exercises

4.69 A car without ABS (antilock brake system) was moving at 15.0 m/s when the driver slammed on the brakes to make a sudden stop. The coefficients of static and kinetic friction between the tires and the road are 0.550 and 0.430, respectively.

a) What was the acceleration of the car during the interval between braking and stopping?

b) How far did the car travel before it stopped?

4.70 A 2.00-kg block (M_1) and a 6.00-kg block (M_2) are connected by a massless string. Applied forces, $F_1 = 10.0\,\text{N}$ and $F_2 = 5.00\,\text{N}$, act on the blocks, as shown in the figure.

a) What is the acceleration of the blocks?

b) What is the tension in the string?

c) What is the net force acting on M_1? (Neglect friction between the blocks and the table.)

4.71 An elevator contains two masses: $M_1 = 2.00\,\text{kg}$ is attached by a string (string 1) to the ceiling of the elevator, and $M_2 = 4.00\,\text{kg}$ is attached by a similar string (string 2) to the bottom of mass 1.

a) Find the tension in string 1 (T_1) if the elevator is moving upward at a constant velocity of v = 3.00 m/s.

b) Find T_1 if the elevator is accelerating upward with an acceleration of a = 3.00 m/s^2.

4.72 What coefficient of friction is required to stop a hockey puck sliding at 12.5 m/s initially over a distance of 60.5 m?

4.73 A spring of negligible mass is attached to the ceiling of an elevator. When the elevator is stopped at the first floor, a mass M is attached to the spring, stretching the spring a distance D until the mass is in equilibrium. As the elevator starts upward toward the

second floor, the spring stretches an additional distance $D/4$. What is the magnitude of the acceleration of the elevator? Assume the force provided by the spring is linearly proportional to the distance stretched by the spring.

4.74 A crane of mass $M = 1.00 \cdot 10^4$ kg lifts a wrecking ball of mass m = 1200. kg directly upward.

a) Find the magnitude of the normal force exerted on the crane by the ground while the wrecking ball is moving upward at a constant speed of v = 1.00 m/s.

b) Find the magnitude of the normal force if the wrecking ball's upward motion slows at a constant rate from its initial speed v = 1.00 m/s to a stop over a distance D = 0.250 m.

4.75 A block of mass 20.0 kg supported by a vertical massless cable is initially at rest. The block is then pulled upward with a constant acceleration of 2.32 m/s^2.

a) What is the tension in the cable?

b) What is the net force acting on the mass?

c) What is the speed of the block after it has traveled 2.00 m?

4.76 Three identical blocks, A, B, and C, are on a horizontal frictionless table. The blocks are connected by strings of negligible mass, with block B between the other two blocks. If block C is pulled horizontally by a force of magnitude F = 12.0 N, find the tension in the string between blocks B and C.

·**4.77** A block of mass $m_1 = 3.00$ kg and a block of mass $m_2 = 4.00$ kg are suspended by a massless string over a frictionless pulley with negligible mass, as in an Atwood machine. The blocks are held motionless and then released. What is the acceleration of the two blocks?

·**4.78** Two blocks of masses m_1 and m_2 are suspended by a massless string over a frictionless pulley with negligible mass, as in an Atwood machine. The blocks are held motionless and then released. If $m_1 = 3.50$ kg, what value does m_2 have to have for the system to experience an acceleration of a = 0.400 g? (*Hint:* There are two solutions to this problem.)

·**4.79** A tractor pulls a sled of mass M = 1000. kg across level ground. The coefficient of kinetic friction between the sled and the ground is $\mu_k = 0.600$. The tractor pulls the sled by a rope that connects to the sled at an angle of $\theta = 30.0^\circ$ above the horizontal. What magnitude of tension in the rope is necessary to move the sled horizontally with an acceleration a = 2.00 m/s^2?

·**4.80** A 2.00-kg block is on a plane inclined at 20.0° with respect to the horizontal. The coefficient of static friction between the block and the plane is 0.600.

a) How many forces are acting on the block?

b) What is the normal force?

c) Is this block moving? Explain.

·**4.81** A block of mass 5.00 kg is sliding at a constant velocity down an inclined plane that makes an angle of 37.0° with respect to the horizontal.

a) What is the friction force?

b) What is the coefficient of kinetic friction?

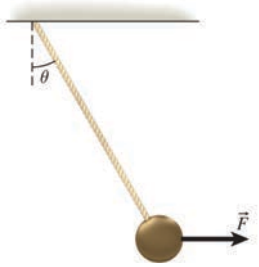
·**4.82** A skydiver of mass 83.7 kg (including outfit and equipment) falls in the spread-eagle position, having reached terminal speed. Her drag coefficient is 0.587, and her surface area that is exposed to the air stream is 1.035 m^2. How long does it take her to fall a vertical distance of 296.7 m? (The density of air is 1.14 kg/m^3.)

·**4.83** A 0.500-kg physics textbook is hanging from two massless wires of equal length attached to a ceiling. The tension on each wire is measured as 15.4 N. What is the angle of the wires with the horizontal?

·**4.84** In the figure, an external force $\vec{F}$ is holding a bob of mass 500. g in a stationary position. The angle that the massless rope makes with the vertical is $\theta = 30.0^\circ$.

a) What is the magnitude, F, of the force needed to maintain equilibrium?

b) What is the tension in the rope?



·**4.85** In a physics class, a 2.70-g Ping-Pong ball was suspended from a massless string. The string makes an angle of $\theta = 15.0^\circ$ with the vertical when air is blown horizontally at the ball at a speed of 20.5 m/s. Assume that the friction force is proportional to the squared speed of the air stream.

a) What is the proportionality constant in this experiment?

b) What is the tension in the string?

·**4.86** A nanowire is a (nearly) one-dimensional structure with a diameter on the order of a few nanometers. Suppose a 100.0-nm-long nanowire made of pure silicon (density of Si = 2.33 g/cm^3) has a diameter of 5.00 nm. This nanowire is attached at the top and hanging down vertically due to the force of gravity.

a) What is the tension at the top?

b) What is the tension in the middle?

(*Hint:* Treat the nanowire as a cylinder of diameter 5.00 nm and length 100.0 nm, made of silicon.)

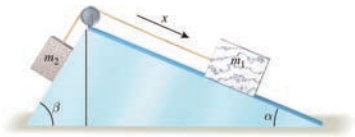
·**4.87** Two blocks are stacked on a frictionless table, and a horizontal force F is applied to the top block (block 1). Their masses are $m_1 = 2.50\,\text{kg}$ and $m_2 = 3.75\,\text{kg}$. The coefficients of static and kinetic friction between the blocks are 0.456 and 0.380, respectively.

a) What is the maximum applied force F for which m_1 will not slide off m_2?

b) What are the accelerations of m_1 and m_2 when the force F = 24.5 N is applied to m_1?

·**4.88** Two blocks ($m_1 = 1.23\,\text{kg}$ and $m_2 = 2.46\,\text{kg}$) are glued together and are moving downward on an inclined plane having an angle of 40.0° with respect to the horizontal. Both blocks are lying flat on the surface of the inclined plane. The coefficients of kinetic

friction are 0.23 for m_1 and 0.35 for m_2. What is the acceleration of the blocks?



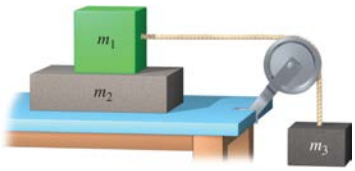
·**4.89** A marble block of mass $m_1 = 567.1$ kg and a granite block of mass $m_2 = 266.4$ kg are connected to each other by a rope that runs over a pulley, as shown in the figure. Both blocks are located on inclined planes, with angles $\alpha = 39.3^\circ$ and $\beta = 53.2^\circ$. Both blocks move without friction, and the rope glides over the pulley without friction. What is the acceleration of the marble block? Note that the positive *x*-direction is indicated in the figure.

··**4.90** A marble block of mass $m_1 = 559.1$ kg and a granite block of mass $m_2 = 128.4$ kg are connected to each other by a rope that runs over a pulley as shown in the figure with Problem 4.89. Both blocks are located on inclined planes with angles $\alpha = 38.3^\circ$ and $\beta = 57.2^\circ$. The rope glides over the pulley without friction, but the coefficient of friction between block 1 and the inclined plane is $\mu_1 = 0.130$, and that between block 2 and the inclined plane is $\mu_2 = 0.310$. (For simplicity, assume that the coefficients of static and kinetic friction are the same in each case.) What is the acceleration of the marble block? Note that the positive *x*-direction is indicated in the figure.

··**4.91** As shown in the figure, two masses, $m_1 = 3.50$ kg and $m_2 = 5.00$ kg, are on a frictionless tabletop and mass $m_3 = 7.60$ kg is hanging from m_1. The coefficients of static and kinetic friction between m_1 and m_2 are 0.600 and 0.500, respectively.

a) What are the accelerations of m_1 and m_2?

b) What is the tension in the string between m_1 and m_3?



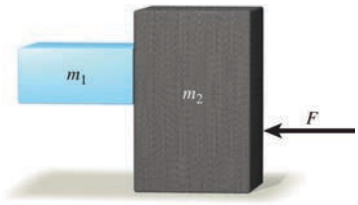
••**4.92** A block of mass $m_1 = 2.30\,\text{kg}$ is placed in front of a block of mass $m_2 = 5.20\,\text{kg}$, as shown in the figure. The coefficient of static friction between m_1 and m_2 is 0.65, and there is negligible friction between the larger block and the tabletop.

a) What forces are acting on m_1?

b) What is the minimum external force F that can be applied to m_2 so that m_1 does not fall?

c) What is the contact force between m_1 and m_2?

d) What is the net force acting on m_2 when the force found in part (b) is applied?

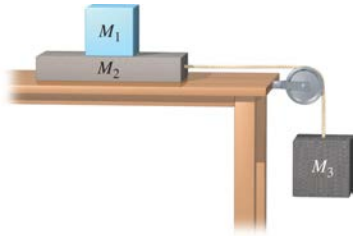


••**4.93** A suitcase of weight Mg = 450. N is being pulled by a small strap across a level floor. The coefficient of kinetic friction between the suitcase and the floor is $\mu_k = 0.640$.

a) Find the optimal angle of the strap above the horizontal. (The optimal angle minimizes the force necessary to pull the suitcase at constant speed.)

b) Find the minimum tension in the strap needed to pull the suitcase at constant speed.

••**4.94** As shown in the figure, a block of mass $M_1 = 0.450\,\text{kg}$ is initially at rest on a slab of mass $M_2 = 0.820\,\text{kg}$, and the slab is initially at rest on a level table. A string of negligible mass is connected to the slab, runs over a frictionless pulley on the edge of the table, and is attached to a hanging mass M_3. The block rests on the slab but is not tied to the string, so friction provides the only horizontal force on the block. The slab has a coefficient of kinetic friction $\mu_k = 0.340$ and a coefficient of static friction $\mu_s = 0.560$ with both the table and the block. When released, M_3 pulls on the string and accelerates the slab, which accelerates the block. Find the maximum mass of M_3 that allows the block to accelerate with the slab, without sliding on top of the slab.



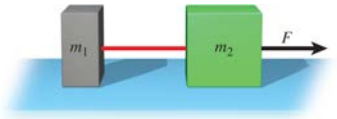
··4.95 As shown in the figure with Problem 4.94, a block of mass $M_1 = 0.250\,\text{kg}$ is initially at rest on a slab of mass $M_2 = 0.420\,\text{kg}$, and the slab is initially at rest on a level table. A string of negligible mass is connected to the slab, runs over a frictionless pulley on the edge of the table, and is attached to a hanging mass $M_3 = 1.80\,\text{kg}$. The block rests on the slab but is not tied to the string, so friction provides the only horizontal force on the block. The slab has a coefficient of kinetic friction $\mu_\text{k} = 0.340$ with both the table and the block. When released, M_3 pulls on the string, which accelerates the slab so quickly that the block starts to slide on the slab. Before the block slides off the top of the slab:

a) Find the magnitude of the acceleration of the block.

b) Find the magnitude of the acceleration of the slab.

MULTI-VERSION EXERCISES

4.96 Two blocks are connected by a massless rope, as shown in the figure. Block 1 has mass $m_1 = 1.267\,\text{kg}$, and block 2 has mass $m_2 = 3.557\,\text{kg}$. The two blocks move on a frictionless, horizontal tabletop. A horizontal external force, F = 12.61 N, acts on block 2. What is the tension in the rope connecting the two blocks?



4.97 Two blocks are connected by a massless rope as shown in the figure. Block 2 has mass $m_2 = 3.557\,\text{kg}$. The two blocks move on a frictionless, horizontal tabletop. A horizontal external force, F = 13.89 N, acts on block 2. The tension in the rope connecting the two blocks is 4.094 N. What is the mass of block 1?

4.98 Two blocks are connected by a massless rope as shown in the figure. Block 1 has mass $m_1 = 1.725\,\text{kg}$. The two blocks move on a frictionless, horizontal tabletop. A horizontal external force, F = 15.17 N, acts on block 2. The tension in the rope connecting the two blocks is 4.915 N. What is the mass of block 2?

4.99 Two blocks are connected by a massless rope as shown in the figure. Block 1 has mass m_1 = 1.955 kg, and block 2 has mass $m_2 = 3.619\,\text{kg}$. The two blocks move on a frictionless, horizontal tabletop. The tension in the rope connecting the two blocks is 5.777 N. What is the magnitude of the horizontal external force F that is acting on block 2?

4.100 Two blocks are connected by a massless rope running over two frictionless pulleys, as shown in the figure. Block 1 has mass $m_1 = 1.183\,\text{kg}$, and block 2 has mass $m_2 = 3.639\,\text{kg}$. The blocks are released from rest. What is the acceleration of block 1?

4.101 Two blocks are connected by a massless rope running over two frictionless pulleys, as shown in the figure. Block 1 has mass $m_1 = 1.411\,\text{kg}$. The blocks are released from rest. Block 1 accelerates upward with an acceleration of $4.352\,\text{m/s}^2$. What is the mass of block 2?

4.102 Two blocks are connected by a massless rope running over two frictionless pulleys, as shown in the figure. Block 2 has mass $m_2 = 3.681\,\text{kg}$. The blocks are released from rest. Block 2 accelerates downward with an acceleration of $3.760\,\text{m/s}^2$. What is the mass of block 1?

4.103 A curling stone of mass 19.00 kg is released with an initial speed v_0 and slides on level ice. The coefficient of kinetic friction between the curling stone and the ice is 0.01869. The curling stone travels a distance of 36.01 m before it stops. What is the initial speed of the curling stone?

4.104 A curling stone of mass 19.00 kg is released with an initial speed $v_0 = 2.788\,\text{m/s}$ and slides on level ice. The coefficient of kinetic friction between the curling stone and the ice is 0.01097. How far does the curling stone travel before it stops?

4.105 A curling stone of mass 19.00 kg is released with an initial speed $v_0 = 3.070\,\text{m/s}$ and slides on level ice. The curling stone travels 36.21 m before it stops. What is the coefficient of kinetic friction between the curling stone and the ice?

Figure 5.1 is a composite image of satellite photographs taken at night, showing which parts of the world use the most energy for nighttime illumination. Not surprisingly, the United States, Western Europe, and Japan stand out. The amount of light emitted by a region during the night is a good measure of the amount of energy that region consumes.

In physics, energy has a fundamental significance: Practically no physical activity takes place without the expenditure or transformation of energy. Calculations involving the energy of a system are of primary importance in all of science and engineering. As we'll see in this chapter, problem-solving methods involving energy provide an alternative to working with Newton's laws and are often simpler and easier to use.

This chapter presents the concepts of kinetic energy, work, and power and introduces some techniques that use these ideas, such as the work–kinetic energy theorem, to solve several types of problems. Chapter 6 will introduce additional types of energy and expand the work–kinetic energy theorem to cover these; it will also discuss one of the great ideas in physics and, indeed, in all of science: the law of conservation of energy.

WHAT WE WILL LEARN

- Kinetic energy is the energy associated with the motion of an object.
- Work is energy transferred to an object or from an object as the result of the action of an external force. Positive work transfers energy to the object, and negative work transfers energy from the object.
- Work is the scalar product of the force vector and the displacement vector.
- The change in kinetic energy due to applied forces is equal to the work done by the forces.
- Power is the rate at which work is done.
- The power provided by a force acting on an object is the scalar product of the velocity vector for that object and the force vector.

5.1 Energy in Our Daily Lives

No physical quantity has a greater importance in our daily lives than energy. Energy consumption, energy efficiency, and energy "production" are of the utmost economic importance and are the focus of heated discussions about national policies and international agreements. (The word *production* is in quotes because energy is not produced but rather is converted from a less usable form to a more usable form.) Energy also has an important role in each individual's daily routine: energy intake through food calories and energy consumption through cellular processes, activities, work, and exercise. Weight loss or weight gain is ultimately due to an imbalance between energy intake and use.

Energy has many forms and requires several different approaches to cover completely. Thus, energy is a recurring theme throughout this book. We start in this chapter and the next by investigating forms of mechanical energy: kinetic energy and potential energy. But as we progress through the topics in this book you will see that other forms of energy are playing very important roles as well. Thermal energy is one of the central pillars of thermodynamics. Chemical energy is stored in chemical compounds, and chemical reactions can either consume energy from the environment (endothermic reactions) or yield usable energy to the surroundings (exothermic reactions). Our petroleum economy makes use of chemical energy and its conversion to mechanical energy and heat, which is another form of energy (or energy transfer).

In Chapter 31, we will see that electromagnetic radiation contains energy. This energy is the basis for one renewable form of energy—solar energy. Almost all other renewable energy sources on Earth can be traced back to solar energy. Solar energy is responsible for the wind that drives large wind turbines (Figure 5.2). The Sun's radiation is also responsible for evaporating water from the Earth's surface and moving it into the clouds, from which it falls down as rain and eventually joins rivers that can be dammed (Figure 5.3) to

extract energy. Biomass, another renewable energy resource, depends on the ability of plants and animals to store solar energy during their metabolic and growth processes.

In fact, the energy radiated onto the surface of Earth by the Sun exceeds the energy needs of the entire human population by a factor of more than 5000. It is possible to convert solar energy directly into electrical energy by using photovoltaic cells (Figure 5.4b). Currently, intense research efforts are focused on increasing the efficiency and reliability of these photocells while reducing their cost. Versions of solar cells are already being used for some practical purposes, for example, in patio and garden lights. Experimental solar farms like the one in Figure 5.4a are in operation as well. The chapter on quantum physics (Chapter 36) will discuss in detail how photocells work. Problems with using solar energy are that it is not available at night, has seasonal variations, and is strongly reduced in cloudy conditions or bad weather. Depending on the installation and conversion methods used, present solar devices convert only 15–20% of solar energy into electrical energy; increasing this fraction is a key goal of research activity. Materials with a 30% or higher yield of electrical energy from solar energy have been developed in the laboratory but are still not deployed on an industrial scale. Using biomass to generate electricity, in comparison, has much lower efficiencies of solar energy capture, on the order of 1% or less.

(a)

(b)

FIGURE 5.4 (a) Solar farm with an adjustable array of mirrors; (b) solar panel.

The Earth itself contains useful energy in the form of heat, which we can harvest using geothermal power plants. Iceland satisfies about half of its energy needs from this resource. The world's largest geothermal power plant complex, the Geysers, is located in Northern California and provides approximately 60% of that region's electricity. Also, the currents, tides, and waves of Earth's oceans can be exploited to extract useful energy. These and other alternative energy resources are the focus of intensive research, and the near future will see impressive developments.

In Chapter 35, on relativity, we will see that energy and mass are not totally separate concepts but are related to each other via Einstein's famous formula $E = mc^2$. When we study nuclear physics (Chapter 40), we will find that splitting massive atomic nuclei (such as uranium or plutonium) liberates energy. Conventional nuclear power plants are based on this physical principle, called *nuclear fission*. We can also obtain useful energy by merging atomic nuclei with very small masses (hydrogen, for example) to form more

massive nuclei, a process called *nuclear fusion*. The Sun and all other stars in the universe use nuclear fusion to generate energy.

The energy from nuclear fusion is thought by many to be the most likely means of satisfying the long-term energy needs of modern industrialized society. Perhaps the most likely approach to achieving progress toward controlled fusion reactions is the proposed international nuclear fusion reactor facility ITER ("the way" in Latin), which is under construction in France. But there are other promising approaches to solving the problem of how to use nuclear fusion, for example, the National Ignition Facility (NIF) opened in May 2009 at Lawrence Livermore National Laboratory in California. We will discuss these technologies in greater detail in Chapter 40.

Related to energy are work and power. We all use these words informally, but this chapter will explain how these quantities relate to energy in precise physical and mathematical terms.

You can see that energy occupies an essential place in our lives. One of the goals of this book is to give you a solid grounding in the fundamentals of energy science. Then you will be able to participate in some of the most important policy discussions of our time in an informed manner.

A final question remains: What is energy? In many textbooks, energy is defined as the ability to do work. However, this definition only shifts the mystery without giving a deeper explanation. And the truth is that there is no deeper explanation. In his famous *Feynman Lectures on Physics,* the Nobel laureate and physics folk hero Richard Feynman wrote in 1963: "It is important to realize that in physics today, we have no knowledge of what energy *is*. We do not have a picture that energy comes in little blobs of a definite amount. It is not that way. However, there are formulas for calculating some numerical quantity, and when we add it all together it gives '28'—always the same number. It is an abstract thing in that it does not tell us the mechanism or the *reasons* for the various formulas." Six decades later, this has not changed. The concept of energy and, in particular, the law of energy conservation (see Chapter 6), are extremely useful tools for figuring out the behavior of systems. But no one has yet given an explanation as to the true nature of energy.

5.2 Kinetic Energy

The first kind of energy we'll consider is the energy associated with the motion of a moving object: **kinetic energy**. Kinetic energy is defined as one-half the product of a moving object's mass and the square of its speed:

$$K = \frac{1}{2}mv^2. \qquad \textbf{(5.1)}$$

Note that, by definition, kinetic energy is always positive or equal to zero, and it is only zero for an object at rest. Also note that kinetic energy, like all forms of energy, is a scalar, not a vector, quantity. Because it is the product of mass (kg) and speed squared (m/s · m/s), the units of kinetic energy are kg m^2/s^2. Because energy is such an important quantity, it has its own SI unit, the **joule (J)**. The SI force unit, the newton, is 1 N = 1 kg m/s^2, and we can make a useful conversion:

$$\text{Energy unit: } 1\ \text{J} = 1\ \text{N m} = 1\ \text{kg m}^2/\text{s}^2. \qquad \textbf{(5.2)}$$

Let's look at a few sample energy values to get a feeling for the size of the joule. A car of mass 1310 kg being driven at the speed limit of 55 mph (24.6 m/s) has a kinetic energy of

$$K_{\text{car}} = \frac{1}{2}mv^2 = \frac{1}{2}(1310\ \text{kg})(24.6\ \text{m/s})^2 = 4.0 \cdot 10^5\ \text{J}.$$

The mass of the Earth is $6.0 \cdot 10^{24}$ kg, and it orbits the Sun with a speed of $3.0 \cdot 10^4$ m/s. The kinetic energy associated with this motion is $2.7 \cdot 10^{33}$ J. A person of mass 64.8 kg jogging at 3.50 m/s has a kinetic energy of 397 J, and a baseball (mass of "5 ounces avoirdupois" = 0.142 kg) thrown at 80. mph (35.8 m/s) has a kinetic energy of 91 J. On the atomic scale, the average kinetic energy of an

air molecule is $6.1 \cdot 10^{-21}$ J, as we will see in Chapter 19. The typical magnitudes of kinetic energies of some moving objects are presented in Figure 5.5. You can see from these examples that the range of energies involved in physical processes is tremendously large.

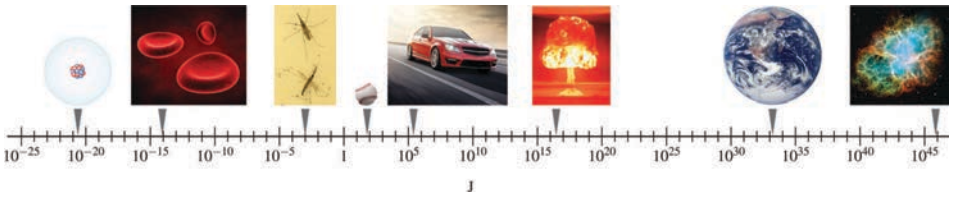

FIGURE 5.5 Range of kinetic energies displayed on a logarithmic scale. The kinetic energies (left to right) of an air molecule, a red blood cell traveling through the aorta, a mosquito in flight, a thrown baseball, a moving car, and the Earth orbiting the Sun are compared with the energy released from a 15-Mt nuclear explosion and by a supernova, which emits particles with a total kinetic energy of approximately 10^{46}J.

Hester and A. Loll (Arizona State University)/NASA

Some other frequently used energy units are the electron-volt (eV), the food calorie (Cal), and the mega-ton (Mt) of TNT:

$$1 \text{ eV} = 1.602 \cdot 10^{-19}\text{J}$$
$$1 \text{ Cal} = 4186 \text{ J}$$
$$1 \text{ Mt} = 4.18 \cdot 10^{15} \text{ J}.$$

On the atomic scale, 1 electron-volt is the kinetic energy that an electron gains when accelerated by an electric potential of 1 volt. The energy content of the food we eat is usually (and mistakenly) given in terms of calories but should be given in food calories. As we'll see when we study thermodynamics, 1 food calorie is equal to 1 kilocalorie; a nice round number to remember is that about 10 MJ (~

2500 food calories) of energy is stored in the food we eat each day. On a larger scale, 1 Mt is the energy released by exploding 1 million metric tons of the explosive TNT, an energy release achieved only by nuclear weapons or by catastrophic natural events such as the impact of a large asteroid. For comparison, in 2007, the annual energy consumption by all humans on Earth reached $5 \cdot 10^{20}$J (see Figure 5.6). (All of these concepts will be discussed further in subsequent chapters.)

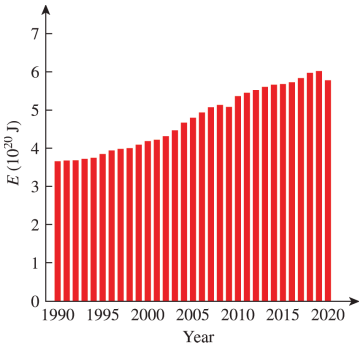

FIGURE 5.6 Total annual global energy consumption by humans from 1990 to 2020. (Data source: yearbook.enerdata.net). McGraw Hill

For motion in more than one dimension, we can write the total kinetic energy as the sum of the kinetic energies associated with the components of velocity in each spatial direction. To show this, we start with the definition of kinetic energy (equation 5.1) and then use $v^2 = v_x^2 + v_y^2 + v_z^2$:

$$K = \frac{1}{2}mv^2 = \frac{1}{2}m\left(v_x^2 + v_y^2 + v_z^2\right) = \frac{1}{2}mv_x^2 + \frac{1}{2}\ mv_y^2 + \frac{1}{2}$$

(*Note:* Kinetic energy is a scalar, so these components are not added like vectors but simply by taking their algebraic sum.) Thus, we can think of kinetic energy as the sum of the kinetic energies associated with the motion in the x-direction, y-direction, and z-direction. This concept is particularly useful for ideal projectile problems, where the motion consists of free fall in the vertical direction (y-direction) and motion with constant velocity in the horizontal direction (x-direction).

EXAMPLE 5.1 Falling Vase

PROBLEM

A crystal vase (mass = 2.40 kg) is dropped from a height of 1.30 m and falls to the floor, as shown in Figure 5.7. What is its kinetic energy just before impact? (Neglect air resistance for now.)

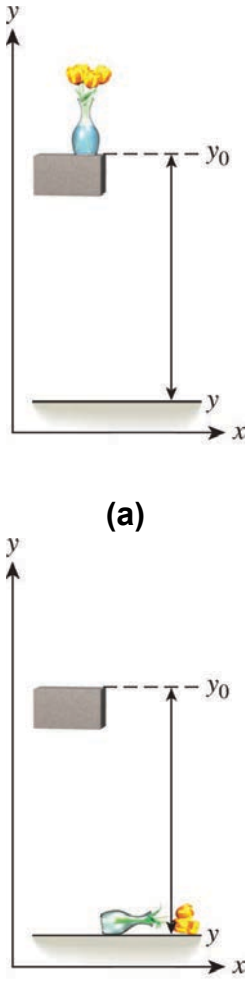

FIGURE 5.7 (a) A vase is released from rest at a height of y_0. (b) The vase falls to the floor, which has a height of y.

SOLUTION

Once we know the velocity of the vase just before impact, we can put it into the equation defining kinetic energy. To obtain this velocity, we recall the kinematics of free-falling objects. In this case, it is most straightforward to use the relationship between

the initial and final velocities and heights that we derived in Chapter 2 for free-fall motion:

$$v_y^2 = v_{y0}^2 - 2g(y - y_0).$$

(Remember that the y-axis must be pointing up to use this equation.) Because the vase is released from rest, the initial velocity components are $v_{x0} = v_{y0} = 0$. Because there is no acceleration in the x-direction, the x-component of velocity remains zero during the fall of the vase: $v_x = 0$. Therefore, we have

$$v^2 = v_x^2 + v_y^2 = 0 + v_y^2 = v_y^2.$$

We then obtain

$$v^2 = v_y^2 = 2g(y_0 - y).$$

We use this result in equation 5.1:

$$K = \frac{1}{2}mv^2 = \frac{1}{2}m(2g(y_0 - y)) = mg(y_0 - y).$$

Inserting the numbers given in the problem statement gives us the answer:

$$K = (2.40\ \text{kg})(9.81\ \text{m/s}^2)(1.30\ \text{m}) = 30.6\ \text{J}.$$

5.3 Work

In Example 5.1, the vase started out with zero kinetic energy, just before it was released. After falling a distance of 1.30 m, it had acquired a kinetic energy of 30.6 J. The greater the height from which the vase is released, the greater the speed the vase will attain (ignoring air resistance), and therefore the greater its kinetic energy becomes. In fact, as we found in Example 5.1, the kinetic energy of the vase depends linearly on the height from which it falls: $K = mg(y_0 - y)$.

The gravitational force, $\vec{F}_g = -mg\hat{y}$, accelerates the vase and therefore gives it its kinetic energy. We can see from the equation we used in Example 5.1 that the kinetic energy also depends linearly on the magnitude of the gravitational force. Doubling the mass of the vase would double the gravitational force acting on it and thus double its kinetic energy.

Because the speed of an object can be increased or decreased by accelerating or decelerating it, respectively, its kinetic energy also changes in this process. For the vase, we have just seen that the force of gravity is responsible for this change. We account for a change in the kinetic energy of an object caused by a force with the concept of **work**, *W*.

Work is the energy transferred to or from an object as the result of the action of a force. Positive work is a transfer of energy to the object, and negative work is a transfer of energy from the object.

The vase gained kinetic energy from positive work done by the gravitational force and so $W_{\mathrm{g}} = mg(y_0 - y)$.

Note that this definition is not restricted to kinetic energy. The relationship between work and energy described in this definition holds in general for different forms of energy besides kinetic energy. This definition of work is not exactly the same as the meaning attached to the word *work* in everyday language. The work being considered in this chapter is mechanical work in connection with

energy transfer. However, the work, physical as well as mental, that we commonly speak of does not necessarily involve the transfer of energy.

5.4 Work Done by a Constant Force

Suppose we let the vase of Example 5.1 slide, from rest, along an inclined plane that has an angle θ with respect to the horizontal (Figure 5.8). For now, we neglect the friction force, but we will come back to it later. As we showed in Chapter 4, in the absence of friction, the acceleration along the plane is given by $a = g \sin \theta = g \cos \alpha$. (Here the angle $\alpha = 90^\circ - \theta$ is the angle between the gravitational force vector and the displacement vector; see Figure 5.8.)

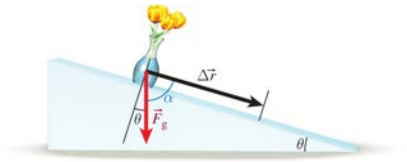

FIGURE 5.8 Vase sliding without friction on an inclined plane.

We can determine the kinetic energy the vase has in this situation as a function of the displacement, $\Delta\vec{r}$. Most conveniently, we can perform this calculation by using the relationship between the squares of initial and final velocities, the displacement, and the acceleration, which we obtained for one-dimensional motion in Chapter 2:

$$v^2 = v_0^2 + 2a\Delta r.$$

We set $v_0 = 0$ because we are again assuming that the vase is released from rest, that is, with zero kinetic energy. Then we use the expression for the acceleration, $a = g \cos \alpha$, that we just obtained. Now we have

$$v^2 = (2g \cos\alpha)\Delta r \Rightarrow K = \frac{1}{2}mv^2 = mg\Delta r \cos \alpha.$$

Self-Test Opportunity 5.1

Draw the free-body diagram for the vase that is sliding down the inclined plane.

The kinetic energy transferred to the vase was the result of positive work done by the gravitational force, and so

$$\Delta K = mg\Delta r \cos\alpha = W_{\mathrm{g}}. \qquad \textbf{(5.4)}$$

Let's look at two limiting cases for equation 5.4:

- For $\alpha = 0$, both the gravitational force and the displacement are in the negative y-direction. Thus, these vectors are parallel, and we have the result we already derived for the case of the vase falling under the influence of gravity, $W_{\mathrm{g}} = mg\Delta r$.
- For $\alpha = 90^{\circ}$, the gravitational force is still in the negative y-direction, but the vase cannot move in the negative y-direction because it is sitting on the horizontal surface of the plane. Hence, there is no change in the kinetic energy of the vase, and there is no work done by the gravitational force on the vase; that is, $W_{\mathrm{g}} = 0$. The work done on the vase by the gravitational force is also zero if the vase moves at a constant speed along the surface of the plane.

Because $mg = \left|\vec{F}_g\right|$ and $\Delta r = \left|\Delta\vec{r}\right|$, we can write the work done on the vase as $W = \left|\vec{F}\right|\left|\Delta\vec{r}\right|\cos\alpha$. From the two limiting cases we have just discussed, we gain confidence that we can use the equation

we have just derived for motion on an inclined plane as the definition of the work done by a constant force:

$$W = \left|\overrightarrow{F}\right|\left|\Delta\overrightarrow{r}\right|\cos\alpha, \text{ where } \alpha \text{ is the angle between } \overrightarrow{F} \text{ and } \Delta\overrightarrow{r}.$$

This equation for the work done by a constant force acting over some spatial displacement holds for all constant force vectors, arbitrary displacement vectors, and angles between the two. Figure 5.9 shows three cases for the work done by a force $\overrightarrow{F}$ acting over a displacement $\overrightarrow{r}$. In Figure 5.9a, the maximum work is done because $\alpha = 0$ and $\overrightarrow{F}$ and $\overrightarrow{r}$ are in the same direction. In Figure 5.9b, $\overrightarrow{F}$ is at an arbitrary angle α with respect to $\overrightarrow{r}$. In Figure 5.9c, no work is done because $\overrightarrow{F}$ is perpendicular to $\overrightarrow{r}$.

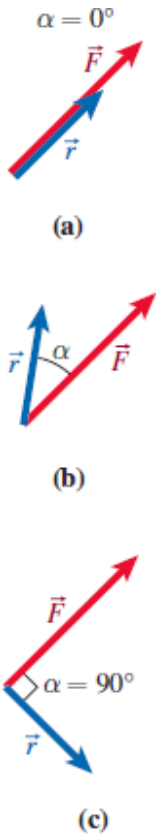

FIGURE 5.9 (a) $\overrightarrow{F}$ is parallel to $\overrightarrow{r}$ and $W = \left|\overrightarrow{F}\right|\left|\overrightarrow{r}\right|$. (b) The angle between $\overrightarrow{F}$ and $\overrightarrow{r}$ is α and $W = \left|\overrightarrow{F}\right|\left|\overrightarrow{r}\right| \cos \alpha$. (c) $\overrightarrow{F}$ is perpendicular to $\overrightarrow{r}$ and $W = 0$.

Using a scalar product (see Section 1.6), we can write the work done by a constant force as

$$W = \overrightarrow{F} \bullet \Delta\overrightarrow{r}. \tag{5.5}$$

This equation is the main result of this section. It says that the work done by a constant force $\vec{F}$ in displacing an object by $\Delta\vec{r}$ is the scalar product of the two vectors. In particular, if the displacement is perpendicular to the force, the scalar product is zero, and no work is done.

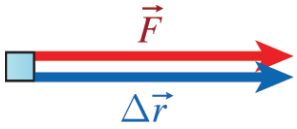
Note that we can use any force vector and any displacement vector in equation 5.5. If there is more than one force acting on an object, the equation holds for any of the individual forces, and it holds for the net force. The mathematical reason for this generalization lies in the distributive property of the scalar product. To verify this statement, we can look at a constant net force that is the sum of individual constant forces, $\vec{F}_{\text{net}} = \sum_i F_i$. According to equation 5.5, the work done by this net force is

$$W_{\text{net}} = \vec{F}_{\text{net}} \bullet \Delta\vec{r} = \left(\sum_i \vec{F}_i\right) \bullet \Delta\vec{r} = \sum_i \left(\vec{F}_i \bullet \Delta\vec{r}\right) = \sum_i W$$

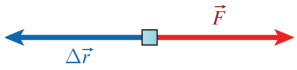
In other words, the net work done by the net force is equal to the sum of the work done by the individual forces. We have demonstrated this additive property of work only for constant forces, but it is also valid for variable forces (or, strictly speaking, only for conservative forces, which we'll encounter in Chapter 6). But to repeat the main point: Equation 5.5 is valid for each individual force as well as the net force. We will typically consider the net force when calculating the work done on an object, but we will omit the index "net" to simplify the notation.

Concept Check 5.1

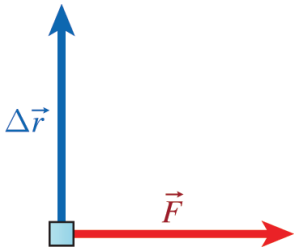
Consider an object undergoing a displacement $\Delta\vec{r}$ and experiencing a force $\vec{F}$. In which of the three cases shown below is the work done by the force on the object zero?



(a)



(b)



(c)

One-Dimensional Case

In all cases of motion in one dimension, the work done to produce the motion is given by

$$\begin{aligned} W &= \vec{F} \bullet \Delta\vec{r} \\ &= \pm F_x \bullet \left|\Delta\vec{r}\right| = F_x \Delta x \\ &= F_x(x - x_0). \end{aligned} \tag{5.6}$$

The force $\vec{F}$ and displacement $\Delta\vec{r}$ can point in the same direction, $\alpha = 0 \Rightarrow \cos\alpha = 1$, resulting in positive work, or they can point in opposite directions, $\alpha = 180^\circ \Rightarrow \cos\alpha = -1$, resulting in negative work.

Work–Kinetic Energy Theorem

The relationship between kinetic energy of an object and the work done by the force(s) acting on it, called the **work–kinetic energy theorem**, is expressed formally as

$$\Delta K \equiv K - K_0 = W. \qquad \textbf{(5.7)}$$

Here, K is the kinetic energy that an object has after work W has been done on it and K_0 is the kinetic energy before the work is done. The definitions of W and K are such that equation 5.7 is equivalent to Newton's Second Law. To see this equivalence, consider a constant force acting in one dimension on an object of mass m. Newton's Second Law is then $F_x = ma_x$, and the (also constant!) acceleration, a_x, of the object is related to the difference in the squares of its initial and final velocities via $v_x^2 - v_{x0}^2 = 2a_x(x - x_0)$ which is one of the five kinematical equations we derived in Chapter 2. Multiplication of both sides of this equation by $\frac{1}{2}m$ yields

$$\tfrac{1}{2}mv_x^2 - mv_{x0}^2 = ma_x(x - x_0) = F_x\Delta x = W. \tfrac{1}{2} \qquad \textbf{(5.8)}$$

Thus, we see that, for this one-dimensional case, the work–kinetic energy theorem is equivalent to Newton's Second Law.

Self-Test Opportunity 5.2

Show the equivalence between Newton's Second Law and the work–kinetic energy theorem for the case of a constant force acting in three-dimensional space.

Because of the equivalence we have just established, if more than one force is acting on an object, we can use the net force to calculate the work done. Alternatively, and more commonly in energy problems, if more than one force is acting on an object, we can calculate the work done by each force, and then W in equation 5.7 represents their sum.

The work–kinetic energy theorem specifies that the change in kinetic energy of an object is equal to the work done on the object by the forces acting on it. We can rewrite equation 5.7 to solve for K or K_0:

$$K = K_0 + W$$

or

$$K_0 = K - W.$$

By definition, the kinetic energy cannot be less than zero; so, if an object has $K_0 = 0$, the work–kinetic energy theorem implies that $K = K_0 + W = W \geq 0$.

While we have only verified the work–kinetic energy theorem for a constant force, it is also valid for variable forces, as we will see below. Is it valid for all kinds of forces? The short answer is no! Friction forces are one kind of force that violate the work–kinetic energy theorem. We will discuss this point further in Chapter 6.

Work Done by the Gravitational Force

With the work–kinetic energy theorem at our disposal, we can now take another look at the problem of an object falling under the influence of the gravitational force, as in Example 5.1. On the way down, the work done by the gravitational force on the object is

$$W_g = +mgh, \tag{5.9}$$

where $h = |y - y_0| = \left|\Delta\vec{r}\right| > 0$. The displacement $\Delta\vec{r}$ and the force of gravity $\vec{F}_g$ point in the same direction, resulting in a positive scalar product and therefore positive work. This situation is illustrated in Figure 5.10a. Since the work is positive, the gravitational force increases the kinetic energy of the object.

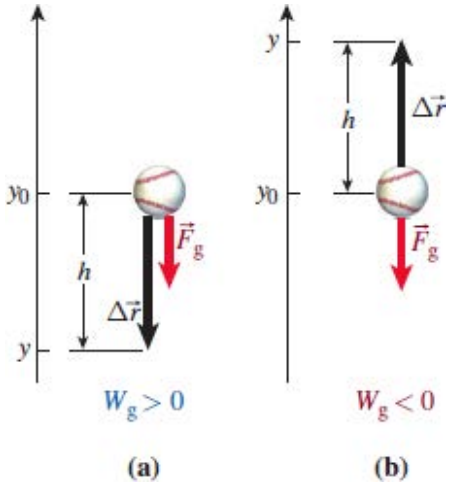


FIGURE 5.10 Work done by the gravitational force. (a) The object during free fall. (b) Tossing an object upward.

We can reverse this situation and toss the object vertically upward, making it a projectile and giving it an initial kinetic energy. This kinetic energy will decrease until the projectile reaches the top of its trajectory. During this time, the displacement vector $\Delta\vec{r}$ points

up, in the opposite direction to the force of gravity (Figure 5.10b). Thus, the work done by the gravitational force during the object's upward motion is

$$W_g = -mgh. \tag{5.10}$$

Therefore, the work done by the gravitational force reduces the kinetic energy of the object during its upward motion. This conclusion is consistent with the general formula for work done by a constant force, $W = \vec{F} \bullet \Delta\vec{r}$ because the displacement (pointing upward) of the object and the gravitational force (pointing downward) are in opposite directions.

Work Done in Lifting and Lowering an Object

Now let's consider the situation in which a vertical external force is applied to an object—for example, by attaching the object to a rope and lifting it up or lowering it down. The work–kinetic energy theorem now has to include the work done by the gravitational force, W_{g}, and the work done by the external force, W_{F}:

$$K - K_0 = W_{\mathrm{g}} + W_{\mathrm{F}}.$$

For the case where the object is at rest both initially, $K_0 = 0$, and finally, $K = 0$, we have

$$W_{\mathrm{F}} = -W_{\mathrm{g}}.$$

The work done by force in lifting or lowering the object is then

$$W_{\mathrm{F}} = -W_{\mathrm{g}} = mgh(\text{for lifting}) \text{ or } W_{\mathrm{F}} = -W_{\mathrm{g}} = -n$$

EXAMPLE 5.2 Weightlifting

In the sport of weightlifting, the task is to pick up a very large mass, lift it over your head, and hold it there at rest for a moment. This action is an example of doing work by lifting and lowering a mass.

PROBLEM 1

The German lifter Ronny Weller won the silver medal at the Olympic Games in Sydney, Australia, in 2000. He lifted 257.5 kg in the "clean and jerk" competition. Assuming he lifted the mass to a height of 1.83 m and held it there, what was the work he did in this process?

SOLUTION 1

This problem is an application of equation 5.11 for the work done against the gravitational force. The work Weller did was

$$W = mgh = (257.5\ \text{kg})\left(9.81\ \text{m/s}^2\right)(1.83\ \text{m}) = 4.62\ \text{kJ}\,.$$

PROBLEM 2

Once Weller successfully completed the lift and was holding the mass with outstretched arms above his head, what was the work done by him in lowering the weight slowly (with negligible kinetic energy) back down to the ground?

SOLUTION 2

This calculation is the same as that in Solution 1 except the sign of the displacement changes. Thus, the answer is that −4.62 kJ of work is done in bringing the weight back down—exactly the opposite of what we obtained for Problem 1!

Now is a good time to remember that we are dealing with strictly mechanical work. Every lifter knows that you can feel the muscles "burn" just as much when holding the mass overhead or lowering the mass (in a controlled way) as when lifting it. (In Olympic competitions, by the way, the weightlifters just drop the mass after the successful lift.) However, this physiological effect is not mechanical work, which is what we are presently

interested in. Instead it is the conversion of chemical energy, stored in different molecules such as sugars, into the energy needed to contract the muscles.

You may think that Olympic weightlifting is not the best example to consider, because the force used to lift the mass is not constant. This is true, but as we discussed previously, the work–kinetic energy theorem applies to nonconstant forces. Additionally, even when a crane lifts a mass very slowly and with constant speed, the lifting force is still not exactly constant, because a slight initial acceleration is needed to get the mass from zero speed to a finite value and a deceleration occurs at the end of the lifting process.

Lifting with Pulleys

When we studied pulleys and ropes in Chapter 4, we learned that pulleys act as force multipliers. For example, with the setup shown in Figure 5.11, the force needed to lift a pallet of bricks of mass m by pulling on the rope is only half the gravitational force, $T = \frac{1}{2}mg$. How does the work done in pulling up the pallet of bricks with ropes and pulleys compare to the work of lifting it without such mechanical aids?

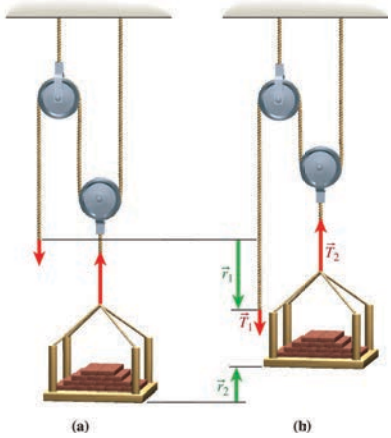

FIGURE 5.11 Forces and displacements for the process of lifting a pallet of bricks at a work site with the aid of a rope-and-pulley mechanism. (a) Pallet in the initial position. (b) Pallet in the final position.

Figure 5.11 shows the initial and final positions of the pallet of bricks and the ropes and pulleys used to lift it. Lifting it without mechanical aids would require the force $\overrightarrow{T_2}$, as indicated, whose magnitude is given by $T_2 = mg$. The work done by force $\overrightarrow{T_2}$ in this

case is $W_2 = \vec{T}_2 \bullet \vec{r}_2 = T_2 r_2 = mgr_2$. Pulling on the rope with force $\vec{T}_1$ of magnitude $T_1 = \frac{1}{2}T_2 = \frac{1}{2}mg$ accomplishes the same thing. However, the displacement is then twice as long, $r_1 = 2r_2$, as you can see by examining Figure 5.11. Thus, the work done in this case is $W_1 = \vec{T}_1 \bullet \vec{r}_1 = \left(\frac{1}{2}T_2\right)(2r_2) = mgr_2 = W_2$.

Concept Check 5.2

If you lift an object a distance *h* with the aid of a rope and *n* pulleys and do work W_h in the process, how much work will be required to lift the same object a distance 2*h*?

a) W_h

b) $2W_h$

c) $0.5W_h$

d) nW_h

e) $2W_h/n$

The same amount of work is done in both cases. It is necessary to compensate for the reduced force by pulling the rope through a longer distance. This result is general for the use of pulleys or lever arms or any other mechanical force multiplier: The total work done is the same as it would be if the mechanical aid were not used. Any reduction in the force is always going to be compensated for by a proportional lengthening of the displacement.

We end this section with a solved problem, which we solve with kinetic energy concepts of Section 5.2. As a double-check step we use the concepts of work for a constant force, which we developed in the present section, showing that both paths lead to the same answer.

SOLVED PROBLEM 5.1 Shot Put

PROBLEM

Shot put competitions use metal balls with a mass of 16 lb (7.26 kg). A competitor throws the shot at an angle of 43.3° and releases it from a height of 1.82 m above where it lands, and it lands a horizontal distance of 17.7 m from the point of release. What is the kinetic energy of the shot as it leaves the thrower's hand?

SOLUTION

THINK

We are given the horizontal distance, $x_s = 17.7$ m, the height of release, $y_0 = 1.82$ m, and the angle of the initial velocity, $\theta_0 = 43.3^\circ$, but not the initial speed, v_0. If we can figure out the initial speed from the given data, then calculating the initial kinetic energy will be straightforward because we also know the mass of the shot: $m = 7.26$ kg.

Because the shot is very heavy, air resistance can be safely ignored. This situation is an excellent realization of ideal projectile motion. After the shot leaves the thrower's hand, the only force on the shot is the force of gravity, and the shot will follow a parabolic trajectory until it lands on the ground. Thus, we'll solve this problem by application of the rules about ideal projectile motion.

SKETCH

The trajectory of the shot is shown in Figure 5.12.

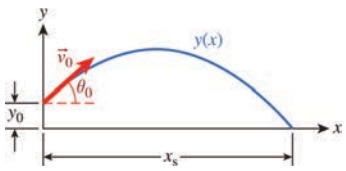

FIGURE 5.12
Parabolic trajectory of a thrown shot.

RESEARCH

The initial kinetic energy K of the shot of mass m is given by

$$K = \frac{1}{2}mv_0^2.$$

Now we need to decide how to obtain v_0. We are given the distance, x_s, to where the shot hits the ground, but this is *not* equal to the range, R (for which we obtained a formula in Chapter 3), because the range formula assumes that the heights of the start and end of the trajectory are equal. Here the initial height of the shot is y_0, and the final height is zero. Therefore, we have to use the full expression for the trajectory of an ideal projectile from Chapter 3:

$$y = y_0 + x\tan\theta_0 - \frac{x^2 g}{2v^2{}_0\cos^2\theta_0}.$$

This equation describes the y-component of the trajectory as a function of the x-component.

In this problem, we know that $y(x = x_s) = 0$, that is, that the shot touches the ground at $x = x_s$. Substituting for x when $y = 0$ in the equation for the trajectory results in

$$0 = y_0 + x_s\tan\theta_0 - x_s^2\ \frac{g}{2v_0^2\cos^2\theta_0}.$$

SIMPLIFY

We solve this equation for v_0^2:

$$y_0 + x_s \tan\theta_0 = \frac{x_s^2 g}{2v_0^2 \cos^2\theta_0} \Rightarrow$$

$$2v_0^2 \cos^2\theta_0 = \frac{x_s^2 g}{y_0 + x_s \tan\theta_0} \Rightarrow$$

$$v_0^2 = \frac{x_s^2 g}{2\cos^2\theta_0 (y_0 + x_s \tan\theta_0)}.$$

Now, substituting for v_0^2 in the expression for the initial kinetic energy gives us

$$K = \tfrac{1}{2} m v_0^2 = \frac{m x_s^2 g}{4\cos^2\theta_0 (y_0 + x_s \tan\theta_0)}$$

CALCULATE

Putting in the given numerical values, we get

$$K = \frac{(7.26\ \text{kg})(17.7\ \text{m})^2 (9.81\text{m/s}^2)}{4(\cos^2 43.3^\circ)[1.82\ \text{m} + (17.7\ \text{m})(\tan 43.3^\circ)]} = 569.$$

ROUND

All of the numerical values given for this problem had three significant figures, so we report our answer as

$$K = 569\ \text{J}.$$

DOUBLE-CHECK

Since we have an expression for the initial speed, $v_0^2 = x_s^2 g / \left[2\cos^2\theta_0 (y_0 + x_s \tan\theta_0)\right]$,we can find the horizontal and vertical components of the initial velocity vector:

$$v_{x0} = v_0 \cos\theta_0 = 9.11\ \text{m/s}$$
$$v_{y0} = v_0 \sin\theta_0 = 8.59\ \text{m/s}.$$

As we discussed in Section 5.2, we can split up the total kinetic energy in ideal projectile motion into contributions from the motion in horizontal and vertical directions (see equation 5.3). The kinetic energy due to the motion in the x-direction remains constant. The kinetic energy due to the motion in the y-direction is initially

$$\tfrac{1}{2}mv_{y0}^2 = \ 268 \text{ J}.$$

At the top of the shot's trajectory, the vertical velocity component is zero, as in all projectile motion. This also means that the kinetic energy associated with the vertical motion is zero at this point. All 268 J of the initial kinetic energy due to the y-component of the motion has been used up to do work against the force of gravity. This work is (refer to equation 5.10) -268 J $= -mgh$, where $h = y_{\text{max}} - y_0$ is the maximum height of the trajectory. We thus find the value of h:

$$h = \frac{268 \text{ J}}{mg} = \frac{268 \text{ J}}{(7.26 \ \text{kg})(9.81 \text{ m/s}^2)} = 3.76 \text{ m}.$$

Page 143

Let's use known concepts of projectile motion to find the maximum height for the initial velocity we have determined. In Section 3.4, the maximum height H of an object in projectile motion was shown to be

$$H = y_0 + \frac{v_{y0}^2}{2g}.$$

Putting in the numbers gives $v_{y0}^2/2g = 3.76$ m. This value is the same as that obtained by applying energy considerations.

5.5 Work Done by a Variable Force

Suppose the force acting on an object is not constant. What is the work done by such a force? In a case of motion in one dimension with a variable x-component of force, $\mathrm{F}_x(x)$, the work is

$$W = \int_{x_0}^{x} F_x(x\prime)dx\prime. \qquad \textbf{(5.12)}$$

(The integrand has x' as a dummy variable to distinguish it from the integral limits.) Equation 5.12 shows that the work W is the area under the curve of $F_x(x)$, (see Figure 5.13 in the following derivation).

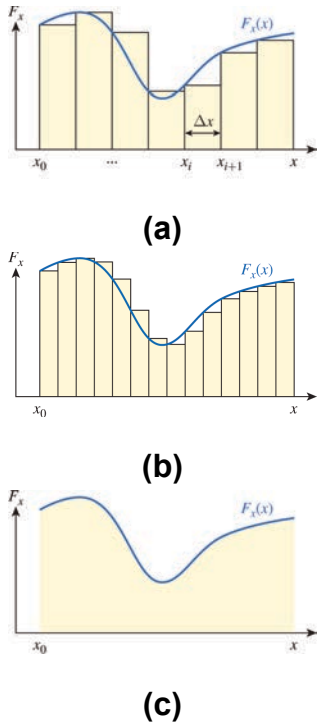

FIGURE 5.13 (a) A series of rectangles approximates the area under the curve obtained by plotting the force as a function of the displacement; (b) a better approximation using rectangles of smaller width; (c) the exact area under the curve.

DERIVATION 5.1

If you have already taken integral calculus, you can skip this section. If equation 5.12 is your first exposure to integrals, the following derivation is a useful introduction. We'll derive the one-dimensional case and use our result for the constant force as a starting point.

In the case of a constant force, we can think of the work as the area under the horizontal line that plots the value of the constant force in the interval between x_0 and x. For a variable force, the work is the area under the curve $F_x(x)$, but that area is no longer a simple rectangle. In the case of a variable force, we need to divide the interval from x_0 to x into many small equal intervals. Then we approximate the area under the curve $F_x(x)$ by a series of rectangles and add their areas to approximate the work. As you can see from Figure 5.13a, the area of the rectangle between x_i and x_{i+1} is given by $F_x(x_i)(x_{i+1} - x_i) = F_x(x_i)\Delta x$. We obtain an approximation for the work by summing over all rectangles:

$$W \approx \sum_i W_i = \sum_i F_x(x_i)\Delta x.$$

Now we space the points x_i closer and closer by using more and more of them. This method makes Δx smaller and causes the total area of the series of rectangles to be a better approximation of the area under the curve $F_x(x)$, as shown in Figure 5.13b. In the limit as $\Delta x \to 0$, the sum approaches the exact expression for the work:

$$W = \lim_{\Delta x \to 0} \left(\sum_i F_x(x_i)\Delta x \right)$$

This limit of the sum of the areas is exactly how the integral is defined:

$$W = \int_{x_0}^{x} F_x(x\prime)dx\prime.$$

We have derived this result for the case of one-dimensional motion. The derivation of the three-dimensional case proceeds along similar lines but is more involved in terms of algebra.

As promised earlier, we can verify that the work–kinetic energy theorem (equation 5.7) is valid when the force is variable. We show this result for one-dimensional motion for simplicity, but the work–kinetic energy theorem also holds for variable forces and displacements in more than one dimension. We assume a variable force in the x-direction, $F_x(x)$, as in equation 5.12, which we can express as

$$F_x(x) = ma,$$

using Newton's Second Law. We use the chain rule of calculus to obtain

$$a = \frac{dv}{dt} = \frac{dv}{dx}\frac{dx}{dt}.$$

We can then use equation 5.12 and integrate over the displacement to get the work done:

$$W = \int_{x_0}^{x} F_x(x\prime)dx\prime = \int_{x_0}^{x} ma\, dx\prime = \int_{x_0}^{x} m\frac{dv}{dx\prime}\frac{dx\prime}{dt}dx\prime.$$

We now change the variable of integration from displacement (x) to velocity (v):

$$W = \int_{x_0}^{x} m\frac{dx\prime}{dt}\frac{dv}{dx\prime}dx\prime = \int_{v_0}^{v} mv\prime dv\prime = m\int_{v_0}^{v} v\prime dv\prime,$$

where v' is a dummy variable of integration. We carry out the integration and obtain the promised result:

$$W = m\int_{v_0}^{v} v\prime dv\prime = m\left[\frac{v\prime^2}{2}\right]_{v_0}^{v} = \frac{1}{2}mv^2 - \frac{1}{2}mv_0^2 = K - K_0 =$$

5.6 Spring Force

Let's examine the force that is needed to stretch or compress a spring. We start with a spring that is neither stretched nor compressed from its normal length and take the end of the spring in this condition to be located at the equilibrium position, x_0, as shown in Figure 5.14a. If we pull the end of this spring a bit toward the right using an external force, $\vec{F}_{\text{ext}}$, the spring gets longer. In the stretching process, the spring generates a force directed to the left, that is, pointing toward the equilibrium position, and increasing in magnitude with increasing length of the spring. This force is conventionally called the **spring force**, $\vec{F}_{\text{s}}$.

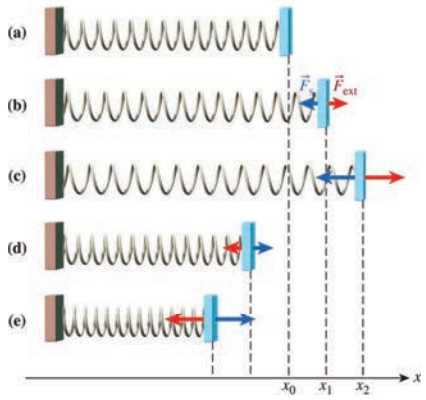

FIGURE 5.14 Spring force. The spring is in its equilibrium position in (a), is stretched in (b) and (c), and is compressed in (d) and (e). In each nonequilibrium case, the external force acting on the end of the spring is shown as a red arrow, and the spring force as a blue arrow.

Pulling with an external force of a given magnitude stretches the spring to a certain displacement from equilibrium, at which point the spring force is equal in magnitude to the external force (Figure 5.14b). Doubling this external force doubles the displacement from equilibrium (Figure 5.14c). Conversely, pushing with an external force toward the left compresses the spring from its equilibrium length, and the resulting spring force points to the right, again toward the equilibrium position (Figure 5.14d). Doubling the amount of compression (Figure 5.14e) also doubles the spring force, just as with stretching.

We can summarize these observations by noting that the magnitude of the spring force is proportional to the magnitude of the displacement of the end of the spring from its equilibrium position, and that the spring force always points toward the equilibrium position and thus is in the direction opposite to the displacement vector:

$$\vec{F}_{\mathrm{s}} = -k\left(\vec{x} - \vec{x}_0\right). \qquad \textbf{(5.13)}$$

As usual, this vector equation can be written in terms of components; in particular, for the *x*-component, we can write

$$F_{\mathrm{s}} = -k(x - x_0). \qquad \textbf{(5.14)}$$

The constant *k* is by definition always positive. The negative sign in front of *k* indicates that the spring force is always directed opposite to the direction of the displacement from the equilibrium position. We can choose the equilibrium position to be $x_0 = 0$, allowing us to write

$$F_{\mathrm{s}} = -kx. \qquad \textbf{(5.15)}$$

This simple force law is called **Hooke's Law**, after the British physicist Robert Hooke (1635–1703), a contemporary of Newton and the Curator of Experiments for the Royal Society. Note that for a displacement $x > 0$, the spring force points in the negative direction, and $F_s < 0$. The converse is also true; if $x < 0$, then $F_s > 0$. Thus, in all cases, the spring force points toward the equilibrium position, $x = 0$. At exactly the equilibrium position, the spring force is zero, $F_s(x = 0) = 0$. As a reminder from Chapter 4, zero force is one of the defining conditions for equilibrium. The proportionality constant, *k*, that appears in Hooke's Law is called the **spring constant** and has units of N/m = kg/s². The spring force is an important example of a **restoring force**: It always acts to restore the end of the spring to its equilibrium position.

Linear restoring forces that follow Hooke's Law can be found in many systems in nature. Examples are the forces on an atom that has moved slightly out of equilibrium in a crystal lattice, the forces due to shape deformations in atomic nuclei, and any other force that leads to oscillations in a physical system (discussed in further detail in Chapters 14 through 16). In Chapter 6, we will see that we can usually approximate the force in many physical situations by a force that follows Hooke's Law.

Of course, Hooke's Law is not valid for all spring displacements. Everyone who has played with a spring knows that if it is stretched too much, it will deform and then not return to its equilibrium length when released. If stretched even further, it will eventually break into two parts. Every spring has an elastic limit—a maximum deformation—below which Hooke's Law is still valid; however, where exactly this limit lies depends on the material characteristics of the particular spring. For our considerations in this chapter, we assume that springs are always inside the elastic limit.

EXAMPLE 5.3 Spring Constant

PROBLEM 1

A spring has a length of 15.4 cm and is hanging vertically from a support point above it (Figure 5.15a). A weight with a mass of 0.200 kg is attached to the spring, causing it to extend to a length of 28.6 cm (Figure 5.15b). What is the value of the spring constant?

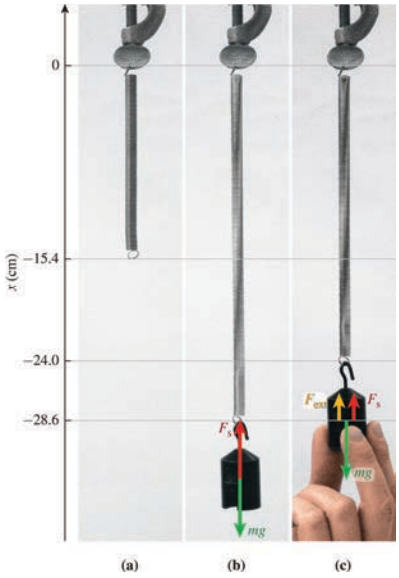

FIGURE 5.15 Mass on a spring. (a) The spring without any mass attached. (b) The spring with the mass hanging freely. (c) The mass pushed upward by an external force.

a-c: W. Bauer and G. D. Westfall

SOLUTION 1

We place the origin of our coordinate system at the top of the spring, with the positive direction upward, as is customary.

Then, $x_0 = -15.4$ cm and $x = -28.6$ cm. According to Hooke's Law, the spring force is

$$F_s = -k(x - x_0).$$

Also, we know the force exerted on the spring was provided by the weight of the 0.200-kg mass: $F = -mg = -(0.200\,\text{kg})\left(9.81\ \text{m/s}^2\right) = -1.962$ N. Again, the negative sign indicates the direction. Now we can solve the force equation for the spring constant:

$$k = -\frac{F_s}{x - x_0} = -\frac{1.962\ \text{N}}{(-0.286\ \text{m}) - (-0.154\ \text{m})} = 14.9\ \text{N/}$$

Note that we would have obtained exactly the same result if we had put the origin of the coordinate system at another point or if we had elected to designate the downward direction as positive.

PROBLEM 2

How much force is needed to hold the weight at a position 4.6 cm above –28.6 cm (Figure 5.15c)?

SOLUTION 2

At first sight, this problem might appear to require a complicated calculation. However, remember that the mass has stretched the spring to a new equilibrium position. To move the mass from that position takes an external force. If the external force moves the mass up 4.6 cm, then it has to be exactly equal in magnitude and opposite in direction to the spring force resulting from a displacement of 4.6 cm. Thus, all we have to do to find the external force is to use Hooke's Law for the spring force (choosing new equilibrium position to be at $x_0 = 0$):

$$F_{\text{ext}} + F_s = 0 \Rightarrow F_{\text{ext}} = -F_s = kx = (0.046\ \text{m})(14.9\ \text{N/m}$$

Self-Test Opportunity 5.3

A block is hanging vertically from a spring at the equilibrium displacement. The block is then pulled down a bit and released from rest. Draw the free-body diagram for the block in each of the following cases:

a) The block is at the equilibrium displacement.

b) The block is at its highest vertical point.

c) The block is at its lowest vertical point.

At this point, it is worthwhile to generalize the observations made in Example 5.3: Adding a constant force—for example, by suspending a mass from the spring—only shifts the equilibrium position. (This generalization is true for all forces that depend linearly on displacement.) Moving the mass, up or down, away from the new equilibrium position then results in a force that is linearly proportional to the displacement from the new equilibrium position. Adding another mass will only cause an additional shift to a new equilibrium position. Of course, adding more mass cannot be continued without limit. At some point, the addition of more and more mass will overstretch the spring. Then the spring will not return to its original length once the mass is removed, and Hooke's Law is no longer valid.

Work Done by the Spring Force

The displacement of a spring is a case of motion in one spatial dimension. Thus, we can apply the one-dimensional integral of equation 5.12 to find the work done by the spring force in moving from x_0 to x. The result is

$$W_{\mathrm{s}} = \int_{x_0}^{x} F_{\mathrm{s}}(x\prime)dx\prime = \int_{x_0}^{x} (-kx\prime)dx\prime = -k\int_{x_0}^{x} x\prime dx\prime.$$

The work done by the spring force is then

$$W_{\mathrm{s}} = -k\int_{x_0}^{x} x\prime dx\prime = -\tfrac{1}{2}kx^2 + \tfrac{1}{2}kx_0^2 \qquad \textbf{(5.16)}$$

If we set $x_0 = 0$ and start at the equilibrium position, as we did in arriving at Hooke's Law (equation 5.15), the second term on the right side in equation 5.16 becomes zero and we obtain

$$W_{\mathrm{s}} = -\tfrac{1}{2}kx^2. \qquad \textbf{(5.17)}$$

Note that because the spring constant is always positive, the work done by the spring force is always negative for displacements from equilibrium. Equation 5.16 shows that the work done by the spring force is positive if the starting spring displacement is farther from equilibrium than the ending displacement. External work of magnitude $\frac{1}{2}kx^2$ will stretch or compress it out of its equilibrium position.

SOLVED PROBLEM 5.2 Compressing a Spring

A massless spring located on a smooth horizontal surface is compressed by a force of 63.5 N, which results in a displacement of 4.35 cm from the initial equilibrium position. As shown in Figure 5.16, a steel ball of mass 0.075 kg is then placed in front of the spring and the spring is released.

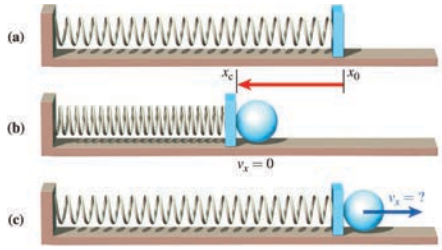

FIGURE 5.16 (a) Spring in its equilibrium position; (b) compressing the spring; (c) relaxing the compression and accelerating the steel ball.

PROBLEM

What is the speed of the steel ball when it is shot off by the spring, that is, right after it loses contact with the spring? (Assume there is no friction between the surface and the steel ball; the steel ball will then simply slide across the surface and will not roll.)

SOLUTION

THINK

If we compress a spring with an external force, we do work against the spring force. Releasing the spring by withdrawing the external force enables the spring to do work on the steel ball, which acquires kinetic energy in this process. Calculating the initial work done against the spring force enables us to figure out

the kinetic energy that the steel ball will have and thus will lead us to the speed of the ball.

SKETCH

We draw a free-body diagram at the instant before the external force is removed (see Figure 5.17). At this instant, the steel ball is at rest in equilibrium, because the external force and the spring force exactly balance each other. Note that the diagram also includes the support surface and shows two more forces acting on the ball: the force of gravity, $\vec{F}_g$, and the normal force from the support surface, $\vec{N}$. These two forces cancel each other out and thus do not enter into our calculations, but it is worthwhile to note the complete set of forces that act on the ball.

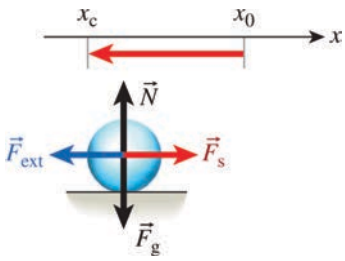

FIGURE 5.17 Free-body diagram of the steel ball before the external force is removed.

We set the x-coordinate of the ball at its left edge, which is where the ball touches the spring. This is the physically relevant location, because it measures the elongation of the spring from its equilibrium position.

RESEARCH

The motion of the steel ball starts once the external force is removed. Without the blue arrow in Figure 5.17, the spring force is the only unbalanced force in the situation, and it accelerates

the ball. This acceleration is not constant over time (as is the case for free-fall motion, for example), but rather changes in time. However, the beauty of applying energy considerations is that we do not need to know the acceleration to calculate the final speed.

As usual, we are free to choose the origin of the coordinate system, and we put it at x_0, the equilibrium position of the spring. This implies that we set $x_0 = 0$. The relation between the x-component of the spring force at the moment of release and the initial compression of the spring x_c is

$$F_\mathrm{s}(x_\mathrm{c}) = -kx_\mathrm{c}.$$

Because $F_\mathrm{s}(x_\mathrm{c}) = -F_\mathrm{ext}$, we find

$$kx_\mathrm{c} = F_\mathrm{ext}.$$

The magnitude of this external force, as well as the value of the displacement, was given, and so we can calculate the value of the spring constant from this equation. Note that with our choice of the coordinate system, $F_\mathrm{ext} < 0$, because its vector arrow points in the negative x-direction. In addition, $x_\mathrm{c} < 0$, because the displacement from equilibrium is in the negative direction.

We can now calculate the work W needed to compress this spring. Since the force that the ball exerts on the spring is always equal and opposite to the force that the spring exerts on the ball, the definition of work allows us to set

$$W = -W_\mathrm{s} = \tfrac{1}{2}kx_\mathrm{c}^2.$$

According to the work–kinetic energy theorem, this work is related to the change in the kinetic energy of the steel ball via

$$K = K_0 + W = 0 + W = \tfrac{1}{2}kx_\mathrm{c}^2.$$

Finally, the ball's kinetic energy is, by definition,

$$K = \tfrac{1}{2}mv_x^2,$$

which allows us to determine the ball's speed.

SIMPLIFY

We solve the equation for the kinetic energy for the speed, v_x, and then use the $K = kx_c^2\frac{1}{2}$ to obtain

$$v_x = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2\left(\frac{1}{2}kx_c^2\right)}{m}} = \sqrt{\frac{kx_c^2}{m}} = \sqrt{\frac{F_{ext}x_c}{m}}.$$

(In the third step, we canceled out the factors 2 and $\frac{1}{2}$, and in the fourth step, we used $kx_c = F_{ext}$.)

CALCULATE

Now we are ready to insert the numbers: $x_c = -0.0435$ m, $m = 0.075$ kg, and $F_{ext} = -63.5$ N. Our result is

$$v_x = \sqrt{\frac{(-63.5\text{ N})(-0.0435\text{ m})}{0.075\text{ kg}}} = 6.06877\text{ m/s}.$$

Note that we choose the positive root for the x-component of the ball's velocity. By examining Figure 5.16, you can see that this is the appropriate choice, because the ball will move in the positive x-direction after the spring is released.

ROUND

Rounding to the two-digit accuracy to which the mass was specified, we state our result as

$$v_x = 6.1\text{ m/s}.$$

DOUBLE-CHECK

We are limited in the checking we can perform to verify that our answer makes sense until we study motion under the influence of the spring force in more detail in Chapter 14. However, our answer passes the minimum requirements in that it has the proper units and the order of magnitude seems in line with typical velocities for balls propelled from spring-loaded toy guns.

Concept Check 5.3

If you compress a spring a distance h from its equilibrium position and do work W_h in the process, how much work will be required to compress the same spring a distance $2h$?

a) W_h

b) $2W_h$

c) $0.5W_h$

d) $4W_h$

e) $0.25W_h$

5.7 Power

We can now readily calculate the amount of work required to accelerate a 1550-kg (3420-lb) car from a standing start to a speed of 26.8 m/s (60.0 mph). The work done is simply the difference between the final and initial kinetic energies. The initial kinetic energy is zero, and the final kinetic energy is

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(1550\ \text{kg})(26.8\ \text{m/s})^2 = 557\ \text{kJ},$$

which is also the amount of work required. However, the work requirement is not that interesting to most of us—we'd be more interested in how quickly the car is able to reach 60 mph. That is, we'd like to know the rate at which the car can do this work.

Power is the rate at which work is done. Mathematically, this means that the power, *P*, is the time derivative of the work, *W*:

$$P = \frac{dW}{dt}. \tag{5.18}$$

It is also useful to define the average power, $\overline{P}$ as

$$\overline{P} = \frac{W}{\Delta t} \tag{5.19}$$

The SI unit of power is the **watt** (W). [Beware of confusing the symbol for work, *W (italicized),* and the abbreviation for the unit of power, W (nonitalicized).]

$$1\ \text{W} = 1\ \text{J/s} = 1\ \text{kg}\ \ \text{m}^2/\text{s}^3. \tag{5.20}$$

Conversely, one joule is also one watt times one second. This relationship is reflected in a very common unit of energy (not

power!), the **kilowatt-hour** (kWh):

$$1 \text{ kWh} = (1000 \text{ W})(3600 \text{ s}) = 3.6 \cdot 10^6 \text{ J} = 3.6 \text{ MJ}.$$

The unit kWh appears on utility bills and quantifies the amount of electrical energy that has been consumed. Kilowatt-hours can be used to measure any kind of energy. Thus, the kinetic energy of the 1550-kg car moving with a speed of 26.8 m/s, which we calculated as 557 kJ, can be expressed with equal validity as

$$(557,000 \text{ J})\left(1 \text{ kWh}/3.6 \cdot 10^6 \text{ J}\right) = 0.155 \text{ kWh}.$$

The two most common non-SI power units are the horsepower (hp) and the foot-pound per second (ft lb/s): 1 hp = 550 ft lb/s = 746 W.

Concept Check 5.4

Is each of the following statements true or false?

a) Work cannot be done in the absence of motion.

b) More power is required to lift a box slowly than to lift a box quickly.

c) A force is required to do work.

It is instructive to look at a logarithmic scale of power consumption of different devices. This is done in the lower row of Figure 5.18. Wristwatches consume about a μW of power, and a green laser pointer is rated up to 5 mW. Among the items in your home a blow dryer has one of the highest power consumption rates at 1 to 2 kW. Cars have engines rated at approximately 100 kW, and a large plane (Boeing 747, Airbus 380) uses on the order of 100 MW to become airborne. The average power consumption of the entire United States is approximately 4 TW. Since there are a little more than 330 million people living in the United States, this means an average power use of approximately 10 kW per person. For comparison, the average power a human needs to stay alive is approximately 100 W (= 10 MJ of food intake per day divided by the number of seconds in a day).

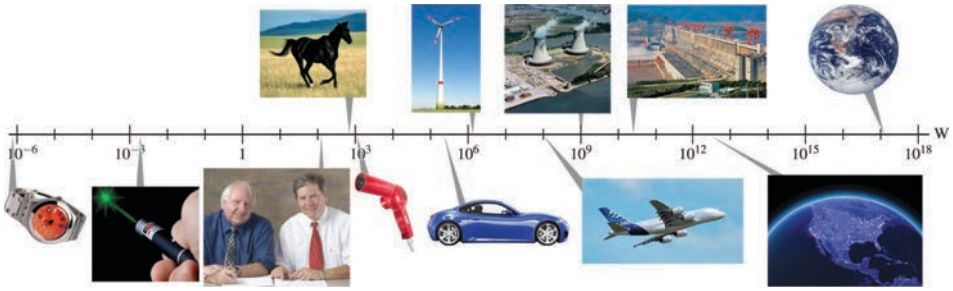

FIGURE 5.18 Logarithmic display of some power sources (upper row of pictures) and power consumption (lower row).

(Black stallion): Alan and Sandy Carey/Photodisc/Getty Images; **(Turbine):** W. Bauer and G. D. Westfall; **(Nuclear Power Plant):** NRC File Photo; **(Dam):** John Henshall/Alamy Stock Photo; **(Earth);** NASA; **(Watch):** Jill Braaten/McGraw Hill; **(Laser pen):** Robin Lund/Alamy Stock Photo; **(Authors' photo):** W. Bauer and G. D. Westfall; **(Hair dryer):** Comstock/Getty Images; **(Car):** rawpixel/123RF; **(Aircraft):** Michele Peterson/Alamy Stock Photo; **(North America):** ixpert/Shutterstock

The upper row of Figure 5.18 lists power sources. On the left we mark 1 horsepower. A typical wind turbine generates on the order of 1 MW, a typical nuclear power plant 1 GW. The largest power producer in the world is the Chinese Three Gorges Dam, completed in 2012, with a peak power production of more than 22 GW. The entire power that the Sun radiates onto the surface of Earth is 175 PW, more than 5000 times the present combined power consumption of all humans.

EXAMPLE 5.4 Accelerating a Car

PROBLEM

Returning to the example of an accelerating car, let's assume that the car, of mass 1550 kg, can reach a speed of 60 mph (26.8 m/s) in 7.1 s. What is the average power needed to accomplish this?

SOLUTION

We already found that the car's kinetic energy at 60 mph is

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(1550\ \text{kg})(26.8\ \text{m/s})^2 = 557\ \text{kJ}\,.$$

The work to get the car to the speed of 60 mph is then

$$W = \Delta K = K - K_0 = 557\ \text{kJ}\,.$$

The average power needed to get to 60 mph in 7.1 s is therefore

$$\overline{P} = \frac{W}{\Delta t} = \frac{5.57 \cdot 10^5 \text{J}}{7.1\ \text{s}} = 78.4\ \text{kW} = 105\ \text{hp}\,.$$

If you own a car with a mass of at least 1550 kg that has an engine with 105 hp, you know that it cannot possibly reach 60 mph in 7.1 s. An engine with at least 180 hp is needed to accelerate a car of mass 1550 kg (including the driver, of course) to 60 mph in that time interval.

Our calculation in Example 5.4 is not quite correct for several reasons. First, not all of the power output of the engine is available to do useful work such as accelerating the car. Second, friction and air resistance forces act on a moving car, but were ignored in Example 5.4. Chapter 6 will address work and energy in the presence of friction forces (rolling friction and air resistance in this case). Finally, a car's rated horsepower is a peak specification, realizable only at the most beneficial rpm-domain of the engine. As you accelerate the car from rest, this peak output of the engine is not maintainable as you shift through the gears.

The average mass, power, and fuel efficiency (for city driving) of mid-sized cars sold in the United States from 1975 to 2010 are shown in Figure 5.19. The mass of a car is important in city driving because of the many instances of acceleration in stop-and-go conditions. We can combine the work–kinetic energy theorem (equation 5.17) and the definition of average power (equation 5.19) to get

$$\overline{P} = \frac{W}{\Delta t} = \frac{\Delta K}{\Delta t} = \frac{\frac{1}{2}mv^2}{\Delta t} = \frac{mv^2}{2\Delta t}. \qquad \textbf{(5.21)}$$

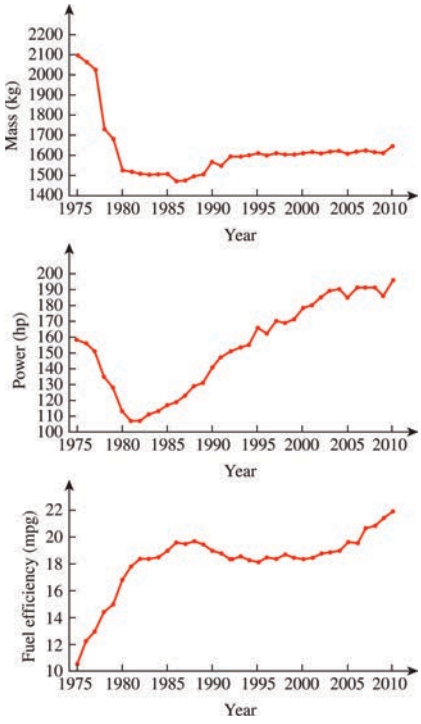

FIGURE 5.19 The mass, power, and fuel efficiency of mid-sized cars sold in the United States from 1975 to 2010. The fuel efficiency is that for typical city driving.

You can see that the average power required to accelerate a car from rest to a speed v in a given time interval, Δt, is proportional to the mass of the car. The energy consumed by the car is equal to the average power times the time interval. Thus, the larger the mass of a car, the more energy is required to accelerate it in a given amount of time.

Following the 1973 oil embargo, the average mass of mid-sized cars decreased from 2100 kg to 1500 kg between 1975 and 1982. During that same period, the average power decreased from 160 hp to 110 hp, and the fuel efficiency increased from 10 to 18 mpg. From 1982 to 2010, however, the average mass and fuel efficiency of mid-sized cars stayed roughly constant, while the power increased steadily. Apparently, buyers of mid-sized cars in the United States have valued increased power over increased efficiency.

SOLVED PROBLEM 5.3 Wind Power

The total electrical power consumption of all humans combined is approximately 3 TW $\left(3 \cdot 10^{12}\ \text{W}\right)$, and it is expected to double during the next 15 to 20 years. Around 62% of the electricity produced comes from fossil fuels; see Figure 5.20. Since the burning of fossil fuels is currently adding more than 20 billion tons of carbon dioxide to Earth's atmosphere per year, it is not clear how much longer this mode of power generation is sustainable. Other sources of power, such as wind, have to be considered. Some huge wind farms have been constructed (see Figure 5.21), and many more are under development. In the year 2000 only 0.2% of global electricity production was due to wind, but in 2020 this percentage had increased to approximately 6%.

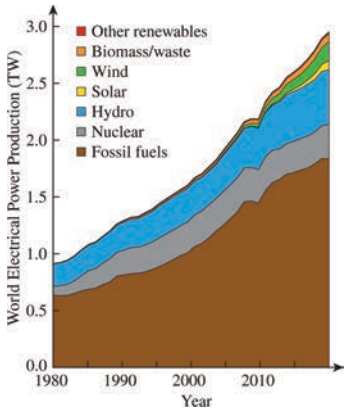

FIGURE 5.20 Worldwide production of electricity as a function of time for different power sources. (Data from www.eia.gov/international/data/world/electricity/)

FIGURE 5.21 Large-scale wind farm producing power.

Thinkstock/Masterfile/Getty Images

PROBLEM

How much average power is contained in wind blowing at 10.0 m/s across the rotor of a large wind turbine, such as the Enercon E-126, which has a hub height of 135 m and a rotor radius of 63 m?

SOLUTION

THINK

Since the wind speed is given, we can calculate the kinetic energy of the amount of air blowing across the rotor's surface. If we can calculate how much air moves across the rotor per unit of time, then we can calculate the power as the ratio of the kinetic energy of the air to the time interval.

SKETCH

The rotor surface is a circle, and we can assume that the wind blows perpendicular to it, because the turbines in wind farms are oriented so that that is the case. Indicated in the sketch (Figure 5.22) is the cylindrical volume of air moving across the rotor per time interval.

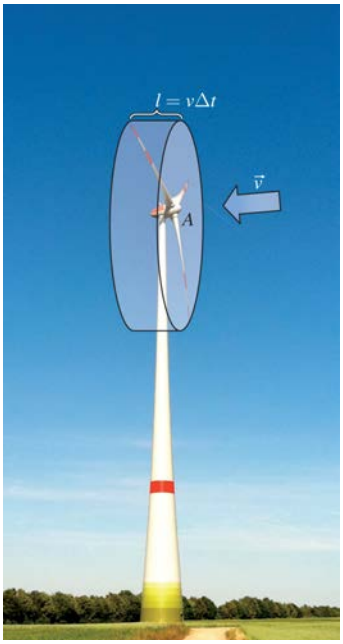

FIGURE 5.22
Sketch for finding the wind power for a large wind turbine.

W. Bauer and G. D. Westfall

RESEARCH

Earlier in this chapter, we learned that the kinetic energy is given by $E = \frac{1}{2}mv^2$; here, m is the mass of air, and v is the wind speed. A very handy rule of thumb is that 1 m^3 of air has a mass of 1.20 kg at sea level and room temperature. The average power is given by $P = W/\Delta t$, and the work is related to the change in kinetic energy through the work–kinetic energy theorem $W = \Delta K$.

We can thus write, for the average power of the wind moving across the rotor of the wind turbine,

$$P = \frac{W}{\Delta t} = \frac{\Delta K}{\Delta t} = \frac{\Delta\left(\frac{1}{2}mv^2\right)}{\Delta t} = \frac{1}{2}v^2\frac{\Delta m}{\Delta t}.$$

In the last step, we have assumed that the wind speed is constant and does not change.

What is Δm? We know that density is mass/volume, and so we can write $\Delta m = {}_{\rho}\Delta V$, where $\rho = 1.20\,\mathrm{kg}/\mathrm{m}^3$ is the air density and ΔV is the volume of air moved across the rotor per unit of time. Here ΔV is a cylinder with length $l = v\Delta t$ and base area A = area of the rotor (see Figure 5.22), v is again the wind speed, and the area is the area of a circle, $A = \pi R^2$.

SIMPLIFY

Now we are ready to insert our expressions for Δm and ΔV into our equation for the average power:

$$P = \tfrac{1}{2}v^2\frac{\Delta m}{\Delta t} = \tfrac{1}{2}v^2\frac{\rho\Delta V}{\Delta t} = \tfrac{1}{2}v^2\frac{\rho Al}{\Delta t} = \tfrac{1}{2}v^2\frac{\rho\left(\pi R^2\right)(v\Delta$$

We see that the average wind power is proportional to the cube of the wind speed!

CALCULATE

Inserting the given numbers for the rotor's radius, the wind speed, and the air density yields

$$P = \tfrac{1}{2}(10.0\mathrm{m/s})^3\left(1.2\mathrm{kg}/\mathrm{m}^3\right)\pi(63\mathrm{m})^2 = 7.481389\cdot 10^6\,\mathrm{k}$$

ROUND

Since the rotor's radius was given to only two significant figures, we round the final result to the same number of significant figures. So our answer is 7.5 MW.

DOUBLE-CHECK

In stating our final result, we replaced $\mathrm{kg\,m^2/s^3}$ with W, which is correct by definition and also means that our answer is dimensionally correct. Although 7.5 MW seems to be a very large amount of power, enough to satisfy the average electricity needs

of approximately 5000 households, this is a gigantic wind turbine. If you look it up on the Internet, you will see that it is rated close to our result. In Example 13.7 we will return to wind turbines and determine what maximum fraction of this total power contained in the wind one can extract.

Obviously, since the wind power is proportional to the cube of the wind speed, it matters *a lot* where wind turbines are located. Figure 5.23 shows a map of average wind speed in the United States. You can see that winds up to 10 m/s are realistic in the central part of the country, from North Dakota to the Texas panhandle, which makes these states prime locations for wind farms.

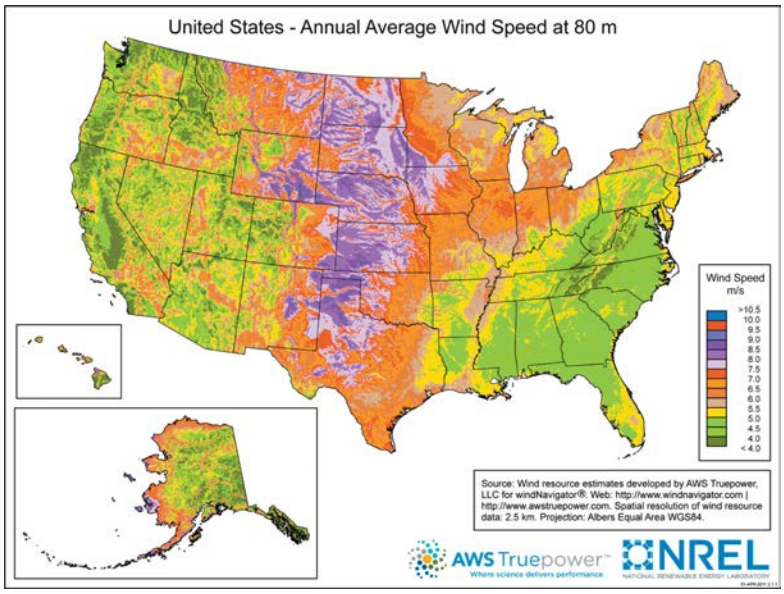

FIGURE 5.23 Map of the United States, showing average wind speed at an altitude of 80 m above ground.

Wind resource map developed by NREL with data from AWS Truepower

Power, Force, and Velocity

For a constant force, the work is given by $W = \vec{F} \bullet \Delta\vec{r}$ and the differential work as $dW = \vec{F} \bullet \vec{dr}$. In this case, the time derivative is

$$P = \frac{dW}{dt} = \frac{\vec{F} \bullet \vec{dr}}{dt} = \vec{F} \bullet \vec{v} = Fv\cos\alpha, \qquad \textbf{(5.22)}$$

where α is the angle between the force vector and the velocity vector. Therefore, the power is the scalar product of the force vector and the velocity vector. While we show this only for a constant force, equation 5.22 also holds for a nonconstant force.

SOLVED PROBLEM 5.4 Riding a Bicycle

PROBLEM

A bicyclist coasts down a 4.2° slope at a steady speed of 5.1 m/s. Assuming a total mass of 82.2 kg (bicycle plus rider), what power output must the cyclist expend to pedal up the same slope at the same speed?

SOLUTION

THINK

If you ride your bike on a horizontal surface and stop pedaling, you slow down to a stop. The net force that causes you to stop is the combination of friction in the mechanical components of the bike and air resistance. In the problem statement, we learned that the bicycle rolls down the hill at a constant speed, which means that the net force acting on it is zero (Newton's First Law!). The force directed along the slope is $mg\sin\theta$ (see Figure 5.24). For the net force to be zero, this force has to be balanced by the forces of friction and air resistance, which act opposite to the direction of motion, or up the slope. So in this case the forces of friction and air resistance have exactly the same magnitude as the component of the gravitational force along the slope. But if the cyclist is pedaling up the same slope, gravity and the forces of air resistance and friction point in the same direction. Thus, we can calculate the total work done against all forces in this case (and only in this case!) by simply calculating the work done against gravity and then multiplying by a factor of 2.

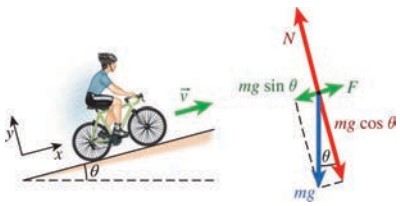

FIGURE 5.24 Sketch of the bicycle moving up the slope (left) and the free-body diagram (right).

SKETCH

Figure 5.24 shows a sketch of the situation where the cyclist is pedaling against gravity.

RESEARCH

We can calculate the work done against gravity, and then multiply it by 2. The component of the gravitational force along the slope is mg sin θ. F is the force exerted by the bicyclist and Power = Fv. Using Newton's Second Law, we have

$$\sum F_x = ma_x = 0 \Rightarrow F - mg\sin\theta = 0 \Rightarrow F = mg\sin\theta.$$

SIMPLIFY

We find the total power the cyclist has to expend by inserting the expression for the force and using the factor of 2, as discussed above: $P = 2Fv = 2(mg\ \sin\ \theta)v$.

CALCULATE

Inserting the given numbers, we get

$$P = 2(82.2\ \text{kg})\left(9.81\ \text{m/s}^2\right)\sin(4.2^\circ)(5.1\ \text{m/s}) = 602.391$$

ROUND

The slope and the speed are given to two significant figures, which is what we round our final answer to: P = 0.60 kW.

DOUBLE-CHECK

Our result is P = 0.60 kW (1 hp/0.746 kW) = 0.81 hp. Thus, going up a 4.2° slope at 5.1 m/s requires approximately 0.8 hp, which is what a good cyclist can expend for quite some time. (But it's hard!)

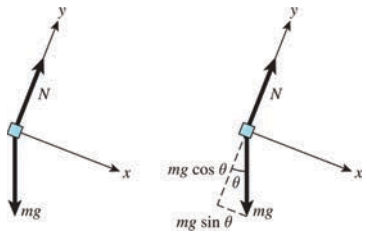
WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- Kinetic energy is the energy associated with the motion of an object, $K = \frac{1}{2}mv^2$.
- The SI unit of work and energy is the joule: $1\ \text{J} = 1\ \text{kg}\ \text{m}^2/\text{s}^2$.
- Work is the energy transferred to an object or transferred from an object as the result of the action of a force. Positive work is a transfer of energy to the object, and negative work is a transfer of energy from the object.
- Work done by a constant force is $W = \left|\vec{F}\right|\left|\Delta\vec{r}\right| \cos\alpha$ where α is the angle between $\vec{F}$ and $\Delta\vec{r}$.
- Work done by a variable force in one dimension is $W = \int_{x_0}^{x} F_x(x\prime)dx\prime$.
- Work done by the gravitational force in the process of lifting an object is $W_g = -mgh < 0$, where $h = |\ y - y_0\ |$; the work done by the gravitational force in lowering an object is $W_g = +mgh > 0$.
- The spring force is given by Hooke's Law: $F_s = -kx$.
- Work done by the spring force is $W = -k\int_{x_0}^{x} x\prime dx\prime = -\frac{1}{2}kx^2 + \frac{1}{2}kx_0^2$.
- The work–kinetic energy theorem is $\Delta K \equiv K - K_0 = W$.
- Power, P, is the time derivative of the work, W: $P = \frac{dW}{dt}$.
- The average power, $\overline{P}$, is $\overline{P} = \frac{W}{\Delta t}$
- The SI unit of power is the watt (W): 1 W = 1 J/s.

- The relationship between power, force, and velocity is $P = \frac{dW}{dt} = \frac{\overrightarrow{F} \bullet \overrightarrow{dr}}{dt} = \overrightarrow{F} \bullet \overrightarrow{v} = Fv\cos\alpha$. where α is the angle between the force vector and the velocity vector.

ANSWERS TO SELF-TEST OPPORTUNITIES

5.1



5.2 $\overrightarrow{F} = m\overrightarrow{a}$ can be rewritten as

$$F_x = ma_x$$
$$F_y = ma_y$$
$$F_z = ma_z$$

for each component

$$v_x^2 - v_{x0}^2 = 2a_x(x - x_0)$$
$$v_y^2 - v_{y0}^2 = 2a_y(y - y_0)$$
$$v_z^2 - v_{z0}^2 = 2a_z(z - z_0)$$

multiply by $\frac{1}{2}\ m$

$$\frac{1}{2}mv_x^2 - \frac{1}{2}mv_{x0}^2 = ma_x(x - x_0)$$
$$\frac{1}{2}mv_y^2 - \frac{1}{2}mv_{y0}^2 = ma_y(y - y_0)$$
$$\frac{1}{2}mv_z^2 - \frac{1}{2}mv_{z0}^2 = ma_z(z - z_0)$$

add the three equations

$$\tfrac{1}{2}m\left(v_x^2+v_y^2+v_z^2\right)-m\left(v_{x0}^2+v_{y0}^2+v_{z0}^2\right)=\tfrac{1}{2}$$

$$ma_x(x-x_0)+ma_y(y-y_0)+ma_z(z-z_0)$$

$$K=\tfrac{1}{2}m\left(v_x^2+v_y^2+v_z^2\right)=\tfrac{1}{2}mv^2$$

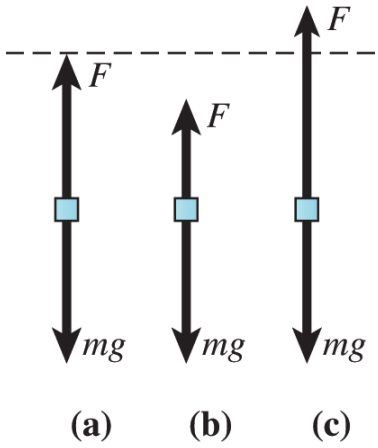
$$K_0=\tfrac{1}{2}m\left(v_{x0}^2+v_{y0}^2+v_{z0}^2\right)=\tfrac{1}{2}mv_0^2$$

$$\Delta\overrightarrow{r}=(x-x_0)\hat{x}+(y-y_0)\hat{y}+(z-z_0)\hat{z}$$

$$\overrightarrow{F}=ma_x\hat{x}+ma_y\hat{y}+ma_z\hat{z}$$

$$K-K_0=\Delta K=\overrightarrow{F}\bullet\Delta\overrightarrow{r}=W$$

5·3



PROBLEM-SOLVING GUIDELINES: KINETIC ENERGY, WORK, AND POWER

1. In all problems involving energy, the first step is to clearly identify the system and the changes in its conditions. If an object undergoes a displacement, check that the displacement is always measured from the same point on the object, such as the front edge or the center of the object. If the speed of the object changes, identify the initial and final speeds at specific points. A diagram is often helpful to show the position and the speed of the object at two different times of interest.

2. Be careful to identify the force that is doing work. Also note whether forces doing work are constant forces or variable forces, because they need to be treated differently.

3. You can calculate the sum of the work done by individual forces acting on an object or the work done by the net force acting on an object; the result should be the same. (You can use this as a way to check your calculations.)

4. Remember that the direction of the restoring force exerted by a spring is always opposite the direction of the displacement of the spring from its equilibrium point.

5. The formula for power, $P = \vec{F} \bullet \vec{v}$, is very useful, if information on the velocity is available. When using the more general definition of power, be sure to distinguish between the average power, $\overline{P} = \dfrac{W}{\Delta t}$, and the instantaneous value of the power, $P = \dfrac{dW}{dt}$.

MULTIPLE-CHOICE QUESTIONS

5.1 Which of the following is a correct unit of energy?

a) kg m/s^2

b) $\text{kg m}^2\text{/s}$

c) $\text{kg m}^2\text{/s}^2$

d) $\text{kg}^2\ \text{m/s}^2$

e) $\text{kg}^2\ \text{m}^2\text{/s}^2$

5.2 An 800-N box is pushed up an inclined plane that is 4.0 m long. It requires 3200 J of work to get the box to the top of the plane, which is 2.0 m above the base. What is the magnitude of the average friction force on the box? (Assume the box starts at rest and ends at rest.)

a) zero

b) not zero but less than 400 N

c) greater than 400 N

d) 400 N

e) 800 N

5.3 An engine pumps water continuously through a hose. If the speed with which the water passes through the hose nozzle is v and if k is the mass per unit length of the water jet as it leaves the nozzle, what is the power being imparted to the water?

a) $\frac{1}{2}kv^3$

b) $\frac{1}{2}kv^2$

c) $\frac{1}{2}kv$

d) $\frac{1}{2}v^2/k$

e) $\frac{1}{2}v^3/k$

5.4 A 1500-kg car accelerates from 0 to 25 m/s in 7.0 s. What is the average power delivered by the engine (1 hp = 746 W)?

a) 60 hp

b) 70 hp

c) 80 hp

d) 90 hp

e) 180 hp

5.5 Which of the following is a correct unit of power?

a) kg $\cdot$ m/s^2

b) N

c) J

d) m/s^2

e) W

5.6 How much work is done when a 75.0-kg person climbs a flight of stairs 10.0 m high at constant speed?

a) $7.36 \cdot 10^5$ J

b) 750 J

c) 75 J

d) 7500 J

e) 7360 J

5.7 How much work do movers do (horizontally) in pushing a 150-kg crate 12.3 m across a floor at constant speed if the coefficient of friction is 0.70?

a) 1300 J

b) 1845 J

c) $1.3 \cdot 10^4$ J

d) $1.8 \cdot 10^4$ J

e) 130 J

5.8 Eight books, each 4.6-cm thick and of mass 1.8 kg, lie on a flat table. How much work is required to stack them on top of one another?

a) 141 J

b) 23 J

c) 230 J

d) 0.81 J

e) 14 J

5.9 A particle moves parallel to the *x*-axis. The net force on the particle increases with *x* according to the formula $F_x = (120\text{N/m})x$, where the force is in newtons when *x* is in meters. How much work does this force do on the particle as it moves from *x* = 0 to *x* = 0.50 m?

a) 7.5 J

b) 15 J

c) 30 J

d) 60 J

e) 120 J

5.10 A skydiver is subject to two forces: gravity and air resistance. Falling vertically, she reaches a constant terminal speed at some time after jumping from a plane. Since she is moving at a constant velocity from that time until her chute opens, we conclude from the work–kinetic energy theorem that, over that time interval,

a) the work done by gravity is zero.

b) the work done by air resistance is zero.

c) the work done by gravity equals the negative of the work done by air resistance.

d) the work done by gravity equals the work done by air resistance.

e) her kinetic energy increases.

5.11 Jack is holding a box that has a mass of *m* kg. He walks a distance of *d* m at a constant speed of *v* m/s. How much work, in joules, has Jack done on the box?

a) mgd

b) $-mgd$

c) $\frac{1}{2}mv^2$

d) $-\frac{1}{2}mv^2$

e) zero

5.12 If negative work is being done by an object, which one of the following statements is true?

a) An object is moving in the negative x-direction.

b) An object has negative kinetic energy.

c) Energy is being transferred from an object.

d) Energy is being transferred to an object.

5.13 The work–kinetic energy theorem is equivalent to

a) Newton's First Law.

b) Newton's Second Law.

c) Newton's Third Law.

d) Newton's Fourth Law.

e) none of Newton's Laws.

5.14 Kathleen climbs a flight of stairs. What can we say about the work done by gravity on her?

a) Gravity does negative work on her.

b) Gravity does positive work on her.

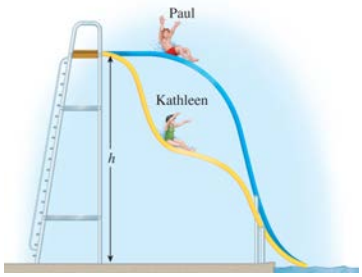
c) Gravity does no work on her.

d) We can't tell what work gravity does on her.

CONCEPTUAL QUESTIONS

5.15 If the net work done on a particle is zero, what can be said about the particle's speed?

5.16 Paul and Kathleen start from rest at the same time at height h at the top of two differently configured water slides. The slides are nearly frictionless. a) Which slider arrives first at the bottom? b) Which slider is traveling faster at the bottom? What physical principle did you use to answer this?



5.17 Does the Earth do any work on the Moon as the Moon moves in its orbit?

5.18 A car, of mass m, traveling at a speed v_1 can brake to a stop within a distance d. If the car speeds up by a factor of 2, so that $v_2 = 2v_1$, by what factor is its stopping distance increased, assuming that the braking force F is approximately independent of the car's speed?

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 5.2

5.19 The damage done by a projectile on impact is correlated with its kinetic energy. Calculate and compare the kinetic energies of these three projectiles:

a) a 10.0-kg stone at 30.0 m/s

b) a 100.0-g baseball at 60.0 m/s

c) a 20.0-g bullet at 300. m/s

5.20 A limo is moving at a speed of 100. km/h. If the mass of the limo, including passengers, is 1900. kg, what is its kinetic energy?

5.21 Two railroad cars, each of mass 7000. kg and traveling at 90.0 km/h, collide head on and come to rest. How much mechanical energy is lost in this collision?

5.22 Think about the answers to these questions next time you are driving a car:

a) What is the kinetic energy of a 1500.-kg car moving at 15.0 m/s?

b) If the car changed its speed to 30.0 m/s, how would the value of its kinetic energy change?

5.23 A 200.-kg moving tiger has a kinetic energy of 14,400 J. What is the speed of the tiger?

•**5.24** Two cars are moving. The first car has twice the mass of the second car but only half as much kinetic energy. When both cars increase their speed by 5.00 m/s, they then have the same kinetic energy. Calculate the original speeds of the two cars.

•**5.25** What is the kinetic energy of an ideal projectile of mass 20.1 kg at the apex (highest point) of its trajectory, if it was launched with an initial speed of 27.3 m/s and at an initial angle of 46.9° with respect to the horizontal?

Section 5.4

5.26 A force of 5.00 N acts over a distance of 12.0 m in the direction of the force. Find the work done.

5.27 Two baseballs are thrown off the top of a building that is 7.25 m high. Both are thrown with initial speed of 63.5 mph. Ball 1 is thrown horizontally, and ball 2 is thrown straight down. What is the difference in the speeds of the two balls when they touch the ground? (Neglect air resistance.)

5.28 A 95.0-kg refrigerator rests on the floor. How much work is required to move it at constant speed for 4.00 m along the floor against a friction force of 180. N?

5.29 A hammerhead of mass m = 2.00 kg is allowed to fall onto a nail from a height h = 0.400 m. Calculate the maximum amount of work it could do on the nail.

5.30 You push your couch a distance of 4.00 m across the living room floor with a horizontal force of 200.0 N. The force of friction is 150.0 N. What is the work done by you, by the friction force, by gravity, and by the net force?

•**5.31** Suppose you pull a sled with a rope that makes an angle of 30.0° to the horizontal. How much work do you do if you pull with 25.0 N of force and the sled moves 25.0 m?

•**5.32** A father pulls his son, whose mass is 25.0 kg and who is sitting on a swing with ropes of length 3.00 m, backward until the ropes make an angle of 33.6° with respect to the vertical. He then releases his son from rest. What is the speed of the son at the bottom of the swinging motion?

•**5.33** A constant force, $\vec{F}$ = (4.79, −3.79, 2.09) N, acts on an object of mass 18.0 kg, causing a displacement of that object by $\vec{r}$ = (4.25, 3.69, −2.45) m. What is the total work done by this force?

•**5.34** A mother pulls her daughter, whose mass is 20.0 kg and who is sitting on a swing with ropes of length 3.50 m, backward until the ropes make an angle of 35.0° with respect to the vertical. She then releases her daughter from rest. What is the speed of the daughter when the ropes make an angle of 15.0° with respect to the vertical?

•5.35 A ski jumper glides down a 30.0° slope for 80.0 ft before taking off from a negligibly short horizontal ramp. If the jumper's takeoff speed is 45.0 ft/s, what is the coefficient of kinetic friction between skis and slope? Would the value of the coefficient of friction be different if expressed in SI units? If yes, by how much would it differ?

•5.36 At sea level, a nitrogen molecule in the air has an average kinetic energy of $6.2 \cdot 10^{-21}$ J. Its mass is $4.7 \cdot 10^{-26}$ kg. If the molecule could shoot straight up without colliding with other molecules, how high would it rise? What percentage of the Earth's radius is this height? What is the molecule's initial speed? (Assume that you can use $g = 9.81\ \text{m/s}^2$; although we'll see in Chapter 12 that this assumption may not be justified for this situation.)

••5.37 A bullet moving at a speed of 153 m/s passes through a plank of wood. After passing through the plank, its speed is 130. m/s. Another bullet, of the same mass and size but moving at 92.0 m/s, passes through an identical plank. What will this second bullet's speed be after passing through the plank? Assume that the resistance offered by the plank is independent of the speed of the bullet.

Section 5.5

•**5.38** A particle of mass m is subjected to a force acting in the x-direction. $F_x = (3.00 + 0.500\text{x})$ N. Find the work done by the force as the particle moves from x = 0.00 to x = 4.00 m.

•**5.39** A force has the dependence $F_x(x) = -kx^4$on the displacement x, where the constant $k = 20.3\ \text{N/m}^4$. How much work does it take to change the displacement, working against the force, from 0.730 m to 1.35 m?

•**5.40** A body of mass m moves along a trajectory $\vec{r}(t)$ in three-dimensional space with constant kinetic energy. What geometric relationship has to exist between the body's velocity vector, $\vec{v}(t)$, and its acceleration vector, $\vec{a}(t)$, in order to accomplish this?

•**5.41** A force given by $\vec{F}(x) = 5x^3\hat{x}\left(\text{in } \text{N/m}^3\right)$ acts on a 1.00-kg mass moving on a frictionless surface. The mass moves from x = 2.00 m to x = 6.00 m.

a) How much work is done by the force?

b) If the mass has a speed of 2.00 m/s at x = 2.00 m, what is its speed at x = 6.00 m?

Section 5.6

5.42 An ideal spring has the spring constant k = 440. N/m. Calculate the distance this spring must be stretched from its equilibrium position for 25.0 J of work to be done.

5.43 A spring is stretched 5.00 cm from its equilibrium position. If this stretching requires 30.0 J of work, what is the spring constant?

5.44 A spring with spring constant k is initially compressed a distance x_0 from its equilibrium length. After returning to its equilibrium position, the spring is then stretched a distance $x_0$from that position. What is the ratio of the work that needs to be done on the spring in the stretching to the work done in the compressing?

•**5.45** A spring with a spring constant of 238.5 N/m is compressed by 0.231 m. Then a steel ball bearing of mass 0.0413 kg is put against the end of the spring, and the spring is released. What is the speed of the ball bearing right after it loses contact with the spring? (The ball bearing will come off the spring exactly as the spring returns to its equilibrium position. Assume that the mass of the spring can be neglected.)

Section 5.7

5.46 A horse draws a sled horizontally across a snow-covered field. The coefficient of friction between the sled and the snow is 0.195, and the mass of the sled, including the load, is 202.3 kg. If the horse moves the sled at a constant speed of 1.785 m/s, what is the power needed to accomplish this?

5.47 A horse draws a sled horizontally on snow at constant speed. The horse can produce a power of 1.060 hp. The coefficient of friction between the sled and the snow is 0.115, and the mass of the sled, including the load, is 204.7 kg. What is the speed with which the sled moves across the snow?

5.48 While a boat is being towed at a speed of 12.0 m/s, the tension in the towline is 6.00 kN. What is the power supplied to the boat through the towline?

5.49 A car of mass 1214.5 kg is moving at a speed of 62.5 mph when it misses a curve in the road and hits a bridge piling. If the car comes to rest in 0.236 s, how much average power (in watts) is expended in this interval?

5.50 An engine expends 40.0 hp in moving a car along a level track at a speed of 15.0 m/s. How large is the total force acting on the car in the direction opposite to the motion of the car?

•5.51 A car of mass 942.4 kg accelerates from rest with a constant power output of 140.5 hp. Neglecting air resistance, what is the speed of the car after 4.55 s?

•**5.52** A bicyclist coasts down a 7.0° slope at a steady speed of 5.0 m/s. Assuming a total mass of 75 kg (bicycle plus rider), what must the cyclist's power output be to pedal up the same slope at the same speed?

•**5.53** A small blimp is used for advertising purposes at a football game. It has a mass of 93.5 kg and is attached by a towrope to a truck on the ground. The towrope makes an angle of 53.3° downward from the horizontal, and the blimp hovers at a constant height of 19.5 m above the ground. The truck moves on a straight line for 840.5 m on the level surface of the stadium parking lot at a constant velocity of 8.90 m/s. If the drag coefficient

$(K \text{ in } F = Kv^2)$ is 0.500 kg/m, how much work is done by the truck in pulling the blimp (assuming there is no wind)?

••**5.54** A car of mass m accelerates from rest along a level straight track, not at a constant acceleration but with constant engine power, P. Assume that air resistance is negligible.

a) Find the car's velocity as a function of time.

b) A second car starts from rest alongside the first car on the same track, but maintains a constant acceleration. Which car takes the initial lead? Does the other car overtake it? If yes, write a formula for the distance from the starting point at which this happens.

c) You are in a drag race, on a straight level track, with an opponent whose car maintains a constant acceleration of $12.0\ \text{m/s}^2$. Both cars have identical masses of 1000. kg. The cars start together from rest. Air resistance is assumed to be negligible. Calculate the minimum power your engine needs for you to win the race, assuming the power output is constant and the distance to the finish line is 0.250 mi.

Additional Exercises

5.55 At the 2004 Olympic Games in Athens, Greece, the Iranian athlete Hossein Rezazadeh won the super-heavyweight class gold medal in weightlifting. He lifted 472.5 kg (1042 lb) combined in his two best lifts in the competition. Assuming that he lifted the weights a height of 196.7 cm, what work did he do?

5.56 How much work is done against gravity in lifting a 6.00-kg weight through a distance of 20.0 cm?

5.57 A certain tractor is capable of pulling with a steady force of 14.0 kN while moving at a speed of 3.00 m/s. How much power in kilowatts and in horsepower is the tractor delivering under these conditions?

5.58 A shot-putter accelerates a 7.30-kg shot from rest to 14.0 m/s. If this motion takes 2.00 s, what average power was supplied?

5.59 An advertisement claims that a certain 1200.-kg car can accelerate from rest to a speed of 25.0 m/s in 8.00 s. What average power must the motor supply in order to cause this acceleration? Ignore losses due to friction.

5.60 A car of mass m = 1250 kg is traveling at a speed of v_0 = 105 km/h (29.2 m/s). Calculate the work that must be done by the brakes to completely stop the car.

5.61 An arrow of mass m = 88.0 g (0.0880 kg) is fired from a bow. The bowstring exerts an average force of F = 110. N on the arrow over a distance d = 78.0 cm (0.780 m). Calculate the speed of the arrow as it leaves the bow.

5.62 The mass of a physics textbook is 3.40 kg. You pick the book up off a table and lift it 0.470 m at a constant speed of 0.270 m/s.

a) What is the work done by gravity on the book?

b) What is the power you supplied to accomplish this task?

5.63 A sled, with mass m, is given a shove up a frictionless incline, which makes a 28.0° angle with the horizontal. Eventually, the sled comes to a stop at a height of 1.35 m above where it started. Calculate its initial speed.

5.64 A man throws a rock of mass m = 0.325 kg straight up into the air. In this process, his arm does a total amount of work $W_{\text{net}} = 115$ J on the rock. Calculate the maximum distance, h, above the man's throwing hand that the rock will travel. Neglect air resistance.

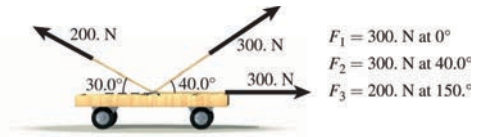
5.65 A car does the work $W_{\text{car}} = 7.00 \cdot 10^4$ J in traveling a distance x = 2.80 km at constant speed. Calculate the average force F (from all sources) acting on the car in this process.

•**5.66** A softball, of mass m = 0.250 kg, is pitched at a speed v_0 = 26.4 m/s. Due to air resistance, by the time it reaches home plate, it has slowed by 10.0%. The distance between the plate and the pitcher is d = 15.0 m. Calculate the average force of air resistance, F_{air}, that is exerted on the ball during its movement from the pitcher to the plate.

•**5.67** A flatbed truck is loaded with a stack of sacks of cement whose combined mass is 1143.5 kg. The coefficient of static friction between the bed of the truck and the bottom sack in the stack is 0.372, and the sacks are not tied down but held in place by the force of friction between the bed and the bottom sack. The truck accelerates uniformly from rest to 56.6 mph in 22.9 s. The stack of sacks is 1 m from the end of the truck bed. Does the stack slide on the truck bed? The coefficient of kinetic friction between the bottom sack and the truck bed is 0.257. What is the work done on the stack by the force of friction between the stack and the bed of the truck?

•**5.68** A driver notices that her 1000.-kg car slows from v_0 = 90.0 km/h (25.0 m/s) to v = 70.0 km/h (19.4 m/s) in t = 6.00 s moving on level ground in neutral gear. Calculate the power needed to keep the car moving at a constant speed, v_{ave} = 80.0 km/h (22.2 m/s). Assume that energy is lost at a constant rate during the deceleration.

•**5.69** The 125-kg cart in the figure starts from rest and rolls with negligible friction. It is pulled by three ropes as shown. It moves 100. m horizontally. Find the final velocity of the cart.



•**5.70** Calculate the power required to propel a 1000.0-kg car at 25.0 m/s up a straight slope inclined 5.00° above the horizontal. Neglect friction and air resistance.

•**5.71** A grandfather pulls his granddaughter, whose mass is 21.0 kg and who is sitting on a swing with ropes of length 2.50 m, backward and releases her from rest. The speed of the granddaughter at the bottom of the swinging motion is 3.00 m/s. What is the angle (in degrees, measured relative to the vertical) from which she is released?

•**5.72** A 65-kg hiker climbs to the second base camp on Nanga Parbat in Pakistan, at an altitude of 3900 m, starting from the first base camp at 2200 m. The climb is made in 5.0 h. Calculate (a) the work done against gravity, (b) the average power output, and (c) the rate of energy input required, assuming the energy conversion efficiency of the human body is 15%.

5.73 An x-component of a force has the dependence $F_x(x) = -cx^3$ on the displacement x, where the constant $c = 19.1\text{N}/\text{m}^3$. How much work does it take to oppose this force and change the displacement from 0.810 m to 1.39 m?

5.74 A massless spring lying on a smooth horizontal surface is compressed by a force of 63.5 N, which results in a displacement of 4.35 cm from the initial equilibrium position. How much work will it take to compress the spring from 4.35 cm to 8.15 cm?

•**5.75** A car is traveling at a constant speed of 26.8 m/s. It has a drag coefficient $c_\text{d} = 0.333$ and a cross-sectional area of $3.25\ \text{m}^2$. How much power is required just to overcome air resistance and keep the car traveling at this constant speed? Assume the density of air is $1.15\ \ \text{kg}/\text{m}^3$.

MULTI-VERSION EXERCISES

5.76 A variable force is given by $F(x) = Ax^6$, where $A = 11.45\ \text{N/m}^6$. This force acts on an object of mass 2.735 kg that moves on a frictionless surface. Starting from rest, the object moves from x = 1.093 m to x = 4.429 m. How much does the kinetic energy of the object change?

5.77 A variable force is given by $F(x) = Ax^6$, where $A = 13.75\ \text{N/m}^6$. This force acts on an object of mass 3.433 kg that moves on a frictionless surface. Starting from rest, the object moves from x = 1.105 m to a new position, x. The object gains $5.662 \cdot 10^3$J of kinetic energy. What is the new position x?

5.78 A variable force is given by $F(x) = Ax^6$, where $A = 16.05\ \text{N/m}^6$. This force acts on an object of mass 3.127 kg that moves on a frictionless surface. Starting from rest, the object moves from a position x_0 to a new position, x = 3.313 m. The object gains $1.00396 \cdot 10^4$ J of kinetic energy. What is the initial position x_0?

5.79 Santa's reindeer pull his sleigh through the snow at a speed of 3.333 m/s. The mass of the sleigh, including Santa and the presents, is 537.3 kg. Assuming that the coefficient of kinetic friction between the runners of the sleigh and the snow is 0.1337, what is the total power (in hp) that the reindeer are providing?

5.80 Santa's reindeer pull his sleigh through the snow at a speed of 2.561 m/s. The mass of the sleigh, including Santa and the presents, is 540.3 kg. Assuming that the reindeer can provide a total power of 2.666 hp, what is the coefficient of friction between the runners of the sleigh and the snow?

5.81 Santa's reindeer pull his sleigh through the snow at a speed of 2.791 m/s. Assuming that the reindeer can provide a total power of 3.182 hp and the coefficient of friction between the runners of the sleigh and the snow is 0.1595, what is the mass of the sleigh, including Santa and the presents?

5.82 A horizontal spring with spring constant k = 15.19 N/m is compressed 23.11 cm from its equilibrium position. A hockey puck with mass m = 170.0 g is placed against the end of the spring. The spring is released, and the puck slides on horizontal ice, with a coefficient of kinetic friction of 0.02221 between the puck and the ice. How far does the hockey puck travel on the ice after it leaves the spring?

5.83 A horizontal spring with spring constant k = 17.49 N/m is compressed 23.31 cm from its equilibrium position. A hockey puck with mass m = 170.0 g is placed against the end of the spring. The spring is released, and the puck slides on horizontal ice a distance of 12.13 m after it leaves the spring. What is the coefficient of kinetic friction between the puck and the ice?

5.84 A load of bricks at a construction site has a mass of 75.0 kg. A crane raises this load from the ground to a height of 45.0 m in 52.0 s at a low constant speed. What is the average power of the crane?

5.85 A load of bricks at a construction site has a mass of 75.0 kg. A crane with 725 W of power raises this load from the ground to a height of 45.0 m at a low constant speed. How long does it take to raise the load?

5.86 A load of bricks at a construction site has a mass of 75.0 kg. A crane with 815 W of power raises this load from the ground to a certain height in 52.0 s at a low constant speed. What is the final height of the load?

Niagara Falls is one of the most spectacular sights in the world, with about 3000 cubic meters of water dropping 49 m (161 ft) every *second!* Horseshoe Falls on the Canadian border, shown in Figure 6.1, has a length of 790 m (2592 ft); American Falls on the United States side extends another 305 m (1001 ft). Together, they are one of the great tourist attractions of North America. However, Niagara Falls is more than a scenic wonder. It is also one of the largest sources of electric power in the world, producing over 2500 megawatts (see Solved Problem 6.1). Humans have exploited the energy of falling water since ancient times, using it to turn large paddlewheels for mills and factories. Today, the conversion of energy in falling water to electrical energy by hydroelectric dams is a major source of energy throughout the world.

FIGURE 6.1 Niagara Falls.

W. Bauer and G. D. Westfall

As we saw in Chapter 5, energy is a fundamental concept in physics that governs many of the interactions involving forces and motions of objects. In this chapter, we continue our study of energy, introducing several new forms of energy and new laws that govern its use. We will return to the laws of energy in the chapters on thermodynamics, building on much of the material presented here. Until then, we will continue our study of mechanics, relying heavily on the ideas discussed here.

WHAT WE WILL LEARN

- Potential energy, *U,* is the energy stored in the configuration of a system of objects that exert forces on one another.
- When a conservative force does work on an object that travels on a path and returns to where it started (a closed path), the total work is zero. A force that does not fulfill this requirement is a nonconservative force.
- A potential energy can be associated with any conservative force. The change in potential energy due to some spatial rearrangement of a system is equal to the negative of the work done by the conservative force during this spatial rearrangement.
- The mechanical energy, *E,* is the sum of kinetic energy and potential energy.
- The total mechanical energy is conserved (it remains constant over time) for any mechanical process that occurs within an isolated system and involves only conservative forces.
- In an isolated system, the total energy—that is, the sum of all forms of energy, mechanical or other—is always conserved. This holds with both conservative and nonconservative forces.
- Small perturbations about a stable equilibrium point result in small oscillations around the equilibrium point; for an unstable equilibrium point, small perturbations result in an accelerated movement away from the equilibrium point.

6.1 Potential Energy

Chapter 5 examined in detail the relationship between kinetic energy and work, and one of the main points was that work and kinetic energy can be converted into one another. Now, this section introduces another kind of energy, called *potential energy*.

Potential energy, *U,* is the energy stored in the configuration of a system of objects that exert forces on one another. For example, we have seen that work is done by an external force in lifting a load against the force of gravity, and this work is given by $W = mgh$, where m is the mass of the load and $h = y - y_0$ is the height to which the load is lifted above its initial position. (In this chapter, we will assume the y-axis points upward unless specified differently.) This lifting can be accomplished without changing the kinetic energy, as in the case of a weightlifter who lifts a mass above his head and holds it there. There is energy stored in holding the mass above the head. If the weightlifter lets go of the mass, this energy can be converted back into kinetic energy as the mass accelerates and falls to the ground. We can express the gravitational potential energy as

$$U_g = mgy. \qquad \textbf{(6.1)}$$

The change in the gravitational potential energy of the mass is then

$$\Delta U_g \equiv U_g(y) - U_g(y_0) = mg(y - y_0) = mgh. \qquad \textbf{(6.2)}$$

(Equation 6.1 is valid only near the surface of the Earth, where $F_g = mg$, and in the limit that Earth is infinitely massive relative to the object. We will encounter a more general expression for U_g in Chapter 12.) In Chapter 5, we found that the work done by the gravitational force on an object that is lifted through a height h is $W_g = -mgh$. From this, we see that the work done by the gravitational force and the gravitational potential energy for an object lifted from rest to a height h are related by

$$\Delta U_{\mathrm{g}} = -W_{\mathrm{g}}. \tag{6.3}$$

EXAMPLE 6.1 Weightlifting

PROBLEM

Let's consider the gravitational potential energy in a specific situation: a weightlifter lifting a barbell of mass m. What is the gravitational potential energy and the work done during the different phases of lifting the barbell?

Page 160

SOLUTION

The weightlifter starts with the barbell on the floor, as shown in Figure 6.2a. At y = 0, the gravitational potential energy can be defined to be $U_g = 0$. The weightlifter then picks up the barbell, lifts it to a height of $y = h/2$, and holds it there, as shown in Figure 6.2b. The gravitational potential energy is now $U_g = mgh$, and the work done by gravity on the barbell is $W_g = -mgh/2$. The weightlifter next lifts the barbell over his head to a height of $y = h$, as shown in Figure 6.2c. The gravitational potential energy is now $U_g = mgh$ and the work done by gravity during this part of the lift is again $W_g = -mgh/2$. Having completed the lift, the weightlifter lets go of the barbell, and it falls to the floor, as illustrated in Figure 6.2d. The gravitational potential energy of the barbell on the floor is again $U_g = 0$, and the work done by gravity during the fall is $W_g = mgh$.

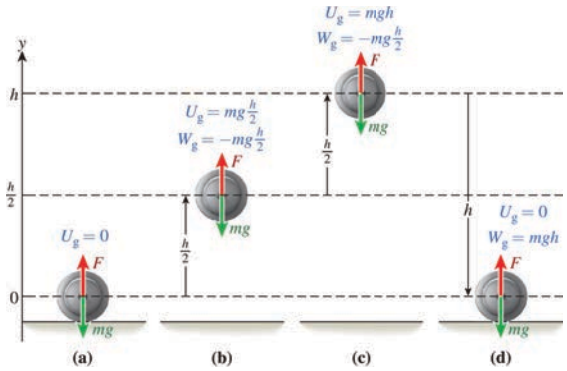

FIGURE 6.2 Lifting a barbell and potential energy (the diagram shows the barbell in side view and omits the weightlifter). The weight of the barbell is *mg,* and the normal force exerted by the floor or the weightlifter to hold the weight up is *F*. (a) The barbell is initially on the floor. (b) The weightlifter lifts the barbell of mass *m* to a height of *h*/2 and holds it there. (c) The weightlifter lifts the barbell an additional distance *h*/2, to a height of *h,* and holds it there. (d) The weightlifter lets the barbell drop to the floor.

Equation 6.3 is true even for complicated paths involving horizontal as well as vertical motion of the object, because the gravitational force does no work during horizontal segments of the motion. In horizontal motion, the displacement is perpendicular to the force of gravity (which always points vertically down), and thus the scalar product between the force and displacement vectors is zero; hence, no work is done.

Lifting any mass to a higher elevation involves doing work against the force of gravity and generates an increase in gravitational potential energy of the mass. This energy can be stored for later use. This principle is employed, for example, at many hydroelectric dams. The excess electricity generated by the turbines is used to pump

water to a reservoir at a higher elevation. There it constitutes a reserve that can be tapped in times of high energy demand and/or low water supply. Stated in general terms, if ΔU_{g} is positive, there exists the potential (hence the name *potential energy*) to allow ΔU_{g} to be negative in the future, thereby extracting positive work, since $W_{\mathrm{g}} = -\Delta U_{\mathrm{g}}$.

SOLVED PROBLEM 6.1 Power Produced by Niagara Falls

PROBLEM

The Niagara River delivers an average of 5520 m^3 of water per second to the top of Niagara Falls, where it drops 49.0 m. If all the potential energy of that water could be converted to electrical energy, how much electrical power could Niagara Falls generate?

SOLUTION

THINK

The mass of 1 m^3 of water is 1000 kg. The work done by the falling water is equal to the change in its gravitational potential energy. The average power is the work per unit time.

Page 161

SKETCH

A sketch of a vertical coordinate axis is superimposed on a photo of Niagara Falls in Figure 6.3.

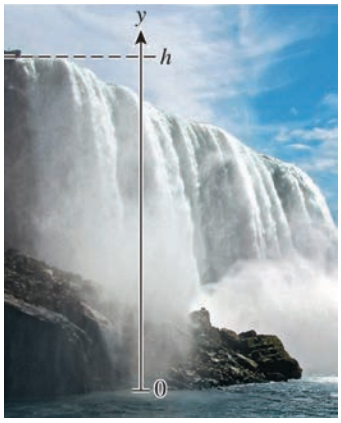

FIGURE 6.3
Niagara Falls, showing an elevation of h for the drop of the water going over the falls.

W. Bauer and G. D. Westfall

RESEARCH

The average power is given by the work per unit time:

$$\overline{P} = \frac{W}{t}.$$

The work that is done by the water going over Niagara Falls is equal to the change in gravitational potential energy,

$$\Delta U = W.$$

The change in gravitational potential energy of a given mass m of water falling a distance h is given by

$$\Delta U = mgh.$$

SIMPLIFY

We can combine the preceding three equations to obtain

$$\overline{P} = \frac{W}{t} = \frac{mgh}{t} = \left(\frac{m}{t}\right)gh.$$

CALCULATE

We first calculate the mass of water moving over the falls per unit time from the given volume of water per unit time, using the density of water:

$$\frac{m}{t} = \left(5520\frac{\text{m}^3}{\text{s}}\right)\left(\frac{1000\text{ kg}}{1\text{ m}^3}\right) = 5.52.10^6\text{ kg/s}.$$

The average power is then

$$\overline{P} = \left(5.52.10^6\text{ kg/s}\right)\left(9.81\text{ m/s}^2\right)(49.0\text{ m}) = 2653.4088\text{ N}$$

ROUND

We round to three significant figures:

$$\overline{P} = 2.65\text{ GW}.$$

DOUBLE-CHECK

Our result is comparable to the output of nuclear power plants, on the order of 1000 MW (1 GW). The combined power generation capability of all of the hydroelectric power stations at Niagara Falls has a peak of 4.4 GW during the high water season in the spring, which is close to our answer. However, you may ask how the water produces power by simply falling over Niagara Falls. The answer is that it doesn't. Instead, a large fraction of the water of the Niagara River is diverted upstream from the falls and sent through tunnels, where it drives power generators. The water that makes it across the falls during the daytime and in the summer tourist season is only about 50% of the flow of the Niagara River. This flow is reduced even further, down to 10%, and more water is diverted for power generation during the nighttime and in the winter.

6.2 Conservative and Nonconservative Forces

Before we can calculate the potential energy from a given force, we have to ask: Can all kinds of forces be used to store potential energy for later retrieval? If not, what kinds of forces can we use? To answer this question, we need to consider what happens to the work done by a force when the direction of the path taken by an object is reversed. In the case of the gravitational force, we have already seen what happens. As shown in Figure 6.4, the work done by F_g when an object of mass m is lifted from elevation y_A to y_B has the same magnitude as, but the opposite sign to, the work done by F_g when lowering the same object from elevation y_B to y_A. This means that the total work done by F_g in lifting the object from some elevation to a different one and then returning it to the same elevation is zero. This fact is the basis for the definition of a conservative force (refer to Figure 6.5a).

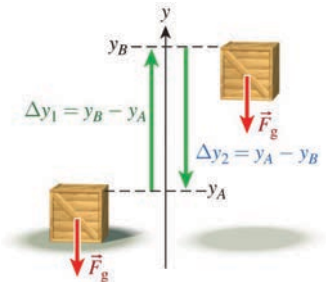

FIGURE 6.4 Gravitational force vectors and displacement for lifting and lowering a box.

A **conservative force** is any force for which the work done over any closed path is zero. A force that does not fulfill this requirement

is called a **nonconservative force**. For conservative forces, we can immediately state two consequences of this definition:

1. If we know the work, $W_{A\to B}$, done by a conservative force on an object as the object moves along a path from point *A* to point *B,* then we also know the work, $W_{B\to A}$, that the same force does on the object as it moves along the path in the reverse direction, from point *B* to point *A* (see Figure 6.5b):

$$W_{B\to A} = -W_{A\to B}(\text{ for conservative forces}). \quad \textbf{(6.4)}$$

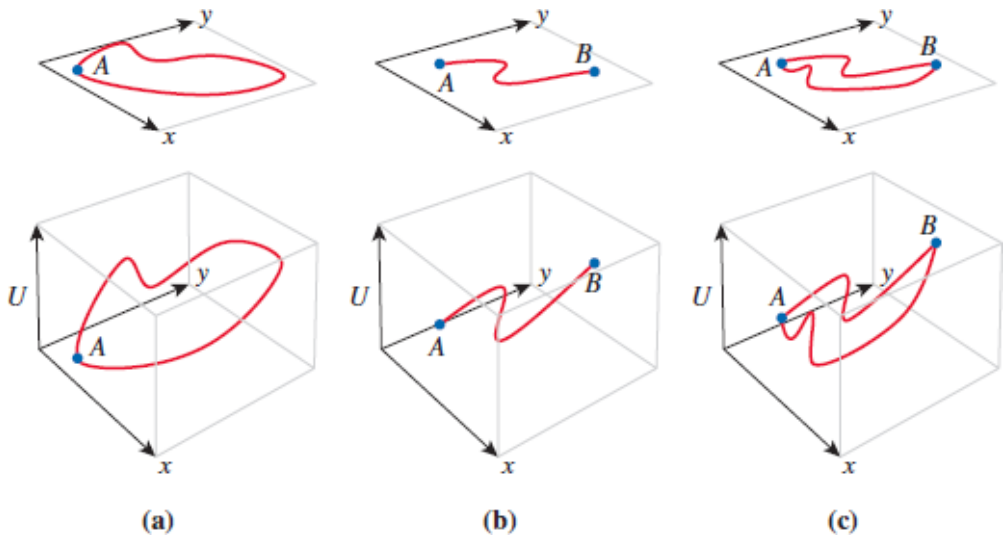

FIGURE 6.5 Various paths for the potential energy related to a conservative force as a function of positions *x* and *y,* with *U* proportional to *y*. The two-dimensional plots are projections of the three-dimensional plots onto the *xy*-plane. (a) Closed loop. (b) A path from point *A* to point *B*. (c) Two different paths between points *A* and *B*.

The proof of this statement is obtained from the condition of zero work over a closed loop. Because the path from *A* to *B* to *A* forms a closed loop, the sum of the work contributions from the loop has to equal zero. In other words,

$$W_{A\to B} + W_{B\to A} = 0,$$

from which equation 6.4 follows immediately.

2. If we know the work, $W_{A\to B,\text{ path }1,}$ done by a conservative force on an object moving along path 1 from point *A* to point *B,* then we also know the work, $W_{A\to B,\text{ path }2,}$ done by the same force on the object when it uses any other path (path 2) to go from point *A* to point *B* (see Figure 6.5c). The work is the same; the work done by a conservative force is independent of the path taken by the object:

$$W_{A\to B,\text{path }2} = W_{A\to B,\text{path }1}$$

$$(\text{for arbitrary paths 1 and 2, for conservative for}$$

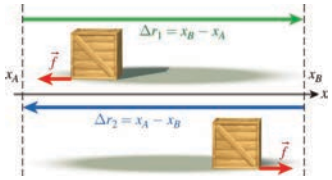

FIGURE 6.6 Friction force vector and displacement vector for the process of sliding a box back and forth across a surface with friction.

This statement is also easy to prove from the definition of a conservative force as a force for which the work done over any closed path is zero. The path from point *A* to point *B* on path 1 and then back from *B* to *A* on path 2 is a closed loop; therefore, $W_{A\to B,\text{path }2} = W_{B\to A,\text{path }1} = 0$. Now we use equation 6.4 for reversal of the path direction, $W_{B\to A,\text{path }1} = -W_{A\to B,\text{path }1}$. Combining these two results gives us $W_{A\to B,\text{path }2} - W_{A\to B,\text{path }1} = 0$, from which equation 6.5 follows.

One physical application of the mathematical results just given involves riding a bicycle from one point, such as your home, to another point, such as the swimming pool. Assuming that your home is located at the foot of a hill and the pool at the top, we can use the Figure 6.5c to illustrate this example, with point *A* representing your home and point *B* the pool. What the preceding statements regarding conservative forces mean is that you do the same amount of work riding your bike from home to the pool, independent of the route you select. You can take a shorter and steeper route or a flatter and longer route; you can even take a route that goes up and down between points *A* and *B*. The total work will be the same. As with almost all real-world examples, however, there are some complications here: It matters whether you use the handbrakes; there is air resistance and tire friction to consider; and your body also performs other metabolic functions during the ride, in addition to moving your mass and that of the bicycle from point *A* to *B*. But this example can help you develop a mental picture of the concepts of path-independence of work and conservative forces.

Page 163

The gravitational force, as we have seen, is an example of a conservative force. Another example of a conservative force is the spring force. Not all forces are conservative, however. Which forces are nonconservative?

Friction Forces

Let's consider what happens in sliding a box across a horizontal surface, from point *A* to point *B* and then back to point *A,* if the coefficient of kinetic friction between the box and the surface is μ_{k} (Figure 6.6). As we have learned, the friction force is given by $f = \mu_{\mathrm{k}}N = \mu_{\mathrm{k}}mg$ and always points in the direction opposite to that of the motion. Let's use results from Chapter 5 to find the work done by this friction force. Since the friction force is constant, the amount of work it does is found by simply taking the scalar product between the friction force and displacement vectors.

For the motion from *A* to *B,* we use the general scalar product formula for work done by a constant force:

$$W_{\mathrm{f1}} = \vec{f} \bullet \Delta\vec{r}_1 = -f \cdot (x_B - x_A) = -\mu_{\mathrm{k}}mg.(x_B - x_A).$$

We have assumed that the positive *x*-axis is pointing to the right, as is conventional, so the friction force points in the negative *x*-direction. For the motion from *B* back to *A,* then, the friction force points in the positive *x*-direction. Therefore, the work done for this part of the path is

$$W_{\mathrm{f2}} = \vec{f} \bullet \Delta\vec{r}_2 = f \cdot (x_A - x_B) = \mu_{\mathrm{k}}mg.(x_A - x_B).$$

This result leads us to conclude that the total work done by the friction force while the box slides across the surface on the closed path from point *A* to point *B* and back to point *A* is not zero, but instead

$$W_{\mathrm{f}} = W_{\mathrm{f1}} + W_{\mathrm{f2}} = -2\mu_{\mathrm{k}}mg(x_B - x_A) < 0. \quad \textbf{(6.6)}$$

There appears to be a contradiction between this result and the work–kinetic energy theorem. The box starts with zero kinetic energy and at a certain position, and it ends up with zero kinetic energy and at the same position. According to the work–kinetic energy theorem, the total work done should be zero. This leads us to conclude that the friction force does not do work in the way that a conservative force does. Instead, the friction force converts kinetic and/or potential

energy into internal excitation energy of the two objects that exert friction on each other (the box and the support surface, in this case). This internal excitation energy can take the form of vibrations or thermal energy or even chemical or electrical energy. The main point is that the conversion of kinetic and/or potential energy to internal excitation energy is not reversible; that is, the internal excitation energy cannot be fully converted back into kinetic and/or potential energy.

Thus, we see that the friction force is an example of a nonconservative force. Because the friction force always acts in a direction opposite to the displacement, the dissipation of energy due to the friction force always reduces the total mechanical energy, whether or not the path is closed. Work done by a conservative force, W, can be positive or negative, but the dissipation from the friction force, W_f, is always negative, withdrawing kinetic and/or potential energy and converting it into internal excitation energy. Using the symbol W_f for this dissipated energy is a reminder that we use the same procedures to calculate it as to calculate work for conservative forces.

Concept Check 6.1

A person pushes a box of mass m a distance d across a floor. The coefficient of kinetic friction between the box and the floor is μ_k. The person then picks up the box, raises it to a height h, carries it back to the starting point, and puts it back down on the floor. How much work has the person done on the box?

a) zero

b) $\mu_k mgd$

c) $\mu_k mgd + 2mgh$

d) $\mu_k mgd - 2mgh$

e) $2\mu_k mgd + 2mgh$

The decisive fact is that the friction force switches direction as a function of the direction of motion and causes dissipation. The friction force vector is always antiparallel to the velocity vector; any force with this property cannot be conservative. Dissipation converts kinetic energy into internal energy of the object, which is another important characteristic of a nonconservative force. In Section 6.7, we will examine this point in more detail.

Another example of a nonconservative force is the force of air resistance. It is also velocity dependent and always points in the direction opposite to the velocity vector, just like the force of kinetic friction. Yet another example of a nonconservative force is the damping force (discussed in Chapter 14). It, too, is velocity dependent and opposite in direction to the velocity.

6.3 Work and Potential Energy

In considering the work done by the gravitational force and its relationship to gravitational potential energy in Section 6.1, we found that the change in potential energy is equal to the negative of the work done by the force, $\Delta U_{\mathrm{g}} = -W_{\mathrm{g}}$. This relationship is true for all conservative forces. In fact, we can use it to define the concept of potential energy.

For any conservative force, the change in potential energy due to some spatial rearrangement of a system is equal to the negative of the work done by the conservative force during this spatial rearrangement:

$$\Delta U = -W. \tag{6.7}$$

We have already seen that work is given by

$$W = \int_{x_0}^{x} F_x(x\prime)dx\prime. \tag{6.8}$$

Combining equations 6.7 and 6.8 gives us the relationship between the conservative force and the potential energy:

$$\Delta U = U(x) - U(x_0) = -\int_{x_0}^{x} F_x(x\prime)dx\prime. \tag{6.9}$$

We could use equation 6.9 to calculate the potential energy change due to the action of any given conservative force. Why should we

bother with the concept of potential energy when we can deal directly with the conservative force itself? The answer is that the change in potential energy depends only on the beginning and final states of the system and is independent of the path taken to get to the final state. Often, we have a simple expression for the potential energy (and thus its change) prior to working a problem! In contrast, evaluating the integral on the right-hand side of equation 6.9 could be quite complicated. And, in fact, the computational savings is not the only rationale, as the use of energy considerations is based on an underlying physical law (the law of energy conservation, to be introduced in Section 6.5).

In Chapter 5, we evaluated the integral in equation 6.9 for the force of gravity and for the spring force. The result for the gravitational force is

$$\Delta U_{\mathrm{g}} = U_{\mathrm{g}}(y) - U_{\mathrm{g}}(y_0) = -\int_{y_0}^{y} (-mg)\,dy\prime = mg\int_{y_0}^{y} dy\prime = mg$$

This is in accord with the result we found in Section 6.1. Consequently, the gravitational potential energy is

$$U_{\mathrm{g}}(y) = mgy + \text{constant}. \qquad \textbf{(6.11)}$$

Note that we are able to determine the potential energy at coordinate y only to within an additive constant. The only physically observable quantity, the work done, is related to the *difference* in the potential energy. If we add an arbitrary constant to the value of the potential energy everywhere, the difference in the potential energies remains unchanged.

In the same way, we find for the spring force that

$$
\begin{aligned}
\Delta U_{\mathrm{s}} &= U_{\mathrm{s}}(x) - U_{\mathrm{s}}(x_0) \\
&= -\int_{x_0}^{x} F_{\mathrm{s}}(x\prime)dx\prime \\
&= \int_{x_0}^{x} (-kx\prime)dx\prime \\
&= k\int_{x_0}^{x} x\prime dx\prime \\
\Delta U_{\mathrm{s}} &= \frac{1}{2}kx^2 - \frac{1}{2}kx_0^2. \qquad \textbf{(6.12)}
\end{aligned}
$$

Thus, the potential energy associated with elongating a spring from its equilibrium position, at x = 0, is

$$U_{\mathrm{s}}(x) = \frac{1}{2}kx^2 + \text{constant}\,. \qquad \textbf{(6.13)}$$

Again, the potential energy is determined only to within an additive constant. However, keep in mind that the physical situation will often force a choice of this additive constant.

6.4 Potential Energy and Force

How can we find the conservative force when we have information on the corresponding potential energy? In calculus, taking the derivative is the inverse operation of integrating, and integration is used in equation 6.9 for the change in potential energy. Therefore, we take the derivative of that expression to obtain the force from the potential energy:

$$F_x(x) = -\frac{dU(x)}{dx}. \tag{6.14}$$

Equation 6.14 is an expression for the force from the potential energy for the case of motion in one dimension. As you can see from this expression, any constant that you add to the potential energy will not have any influence on the result you obtain for the force, because taking the derivative of a constant term results in zero. This is further evidence that the potential energy can be determined only within an additive constant.

We will not consider motion in three-dimensional situations until later in this book. However, for completeness, we can state the expression for the force from the potential energy for the case of three-dimensional motion:

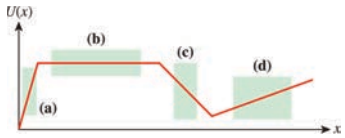
$$\vec{F}\left(\vec{r}\right) = -\left(\frac{\partial U\left(\vec{r}\right)}{\partial x}\,\hat{x} + \frac{\partial U\left(\vec{r}\right)}{\partial y}\,\hat{y} + \frac{\partial U\left(\vec{r}\right)}{\partial z}\,\hat{z} \right). \tag{6.15}$$

Here, the force components are given as partial derivatives with respect to the corresponding coordinates. If you major in engineering or science, you will encounter partial derivatives in many situations, certainly in higher-level calculus classes during your undergraduate

studies. Basically, to take a partial derivative with respect to x, you follow the usual calculus process for finding a derivative and treat the variables y and z as constants. To take a partial derivative with respect to y, you treat x and z as constants, and to take a partial derivative with respect to z, you treat x and y as constants. We will revisit multidimensional potential energy surfaces in Chapter 11, when we talk about stability.

Concept Check 6.2

The potential energy, $U(x)$, is shown as a function of position, x, in the figure. In which region is the magnitude of the force the highest?



Lennard-Jones Potential

Empirically, the potential energy associated with the interaction of two atoms in a molecule as a function of the separation of the atoms has a form that is called the *Lennard-Jones potential*. This potential energy as a function of the separation, *x*, is given by

$$U(x) = 4U_0\left(\left(\frac{x_0}{x}\right)^{12} - \left(\frac{x_0}{x}\right)^{6}\right). \qquad \textbf{(6.16)}$$

Here U_0 is a constant energy and x_0 is a constant distance. The Lennard-Jones potential is one of the most important concepts in atomic physics and is used for most numerical simulations of molecular systems.

EXAMPLE 6.2 Molecular Force

PROBLEM

What is the force resulting from the Lennard-Jones potential?

SOLUTION

We simply take the negative of the derivative of the potential energy with respect to x:

$$\begin{aligned} F_x(x) &= -\frac{dU(x)}{dx} \\ &= -\frac{d}{dx}\left(4U_0\left(\left(\frac{x_0}{x}\right)^{12} - \left(\frac{x_0}{x}\right)^{6}\right)\right) \\ &= -4U_0 x_0^{12}\frac{d}{dx}\left(\frac{1}{x^{12}}\right) + 4U_0 x_0^{6}\frac{d}{dx}\left(\frac{1}{x^{6}}\right) \\ &= 48U_0 x_0^{12}\frac{1}{x^{13}} - 24U_0 x_0^{6}\frac{1}{x^{7}} \\ &= \frac{24U_0}{x_0}\left(2\left(\frac{x_0}{x}\right)^{13} - \left(\frac{x_0}{x}\right)^{7}\right). \end{aligned}$$

PROBLEM

At what value of x does the Lennard-Jones potential have its minimum?

SOLUTION

Since we just found that the force is the derivative of the potential energy function, all we have to do is find the point(s) where $F(x) = 0$. This leads to

$$F_x(x)\big|_{x=x_{\min}} = \frac{24U_0}{x_0}\left(2\left(\frac{x_0}{x_{\min}}\right)^{13} - \left(\frac{x_0}{x_{\min}}\right)^{7}\right) = 0.$$

This condition can be fulfilled only if the expression in the larger parentheses is zero; thus

$$2\left(\frac{x_0}{x_{\text{min}}}\right)^{13} = \left(\frac{x_0}{x_{\text{min}}}\right)^{7}.$$

Multiplying both sides by $x_{\text{min}}^{13} x_0^{-7}$ then yields

$$2x_0^6 = x_{\text{min}}^6$$

or

$$x_{\text{min}} = 2^{1/6} x_0 \approx 1.1225 x_0.$$

Mathematically, it is not enough to show that the derivative is zero to establish that the potential indeed has a minimum at this coordinate. We should also make sure that the second derivative is positive. You can do this as an exercise.

Figure 6.7a shows the shape of the Lennard-Jones potential, plotted from equation 6.16, with $x_0 = 0.34\,\text{nm}$ and $U_0 = 1.70 \cdot 10^{-21}\text{J}$, for the interaction of two argon atoms as a function of the separation of the centers of the two atoms. Figure 6.7b plots the corresponding molecular force, using the expression we found in Example 6.2. The vertical gray dashed line marks the coordinate where the potential has a minimum and where consequently the force is zero. Also note that close to the minimum point of the potential (within ±0.1 nm), the force can be closely approximated by a linear function, $F_x(x) \approx -k(x - x_{\text{min}})$. This means that close to the minimum, the molecular force due to the Lennard-Jones potential behaves like a spring force.

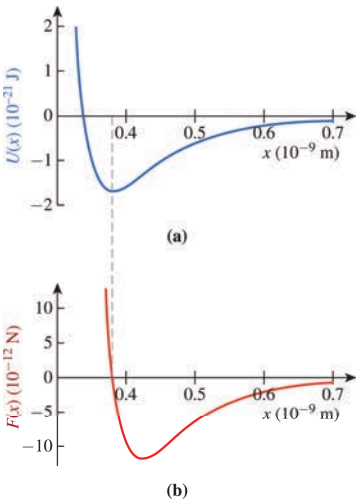


FIGURE 6.7 (a) Dependence of the potential energy on the *x*-coordinate of the potential energy function in equation 6.16. (b) Dependence of the force on the *x*-coordinate of the potential energy function in equation 6.16.

Chapter 5 mentioned that forces similar to the spring force appear in many physical systems, and the connection between potential energy and force just described tells us why. Look, for example, at the skateboarder in the half-pipe in Figure 6.8. The curved surface of the half-pipe approximates the shape of the Lennard-Jones potential close to the minimum. If the skateboarder is at $x = x_{\text{min}}$, he can remain there at rest. If he is to the left of the minimum, where $x < x_{\text{min}}$, then the half-pipe exerts a force on him, which points to the right, $F_x > 0$; the further to the left he moves, the bigger the force becomes. On the right side of the half-pipe, for $x > x_{\text{min}}$, the force points to the left, that is, $F_x < 0$. Again, these observations can be summarized with a force expression that approximately follows Hooke's Law: $F_x(x) = -k(x - x_{\text{min}})$.

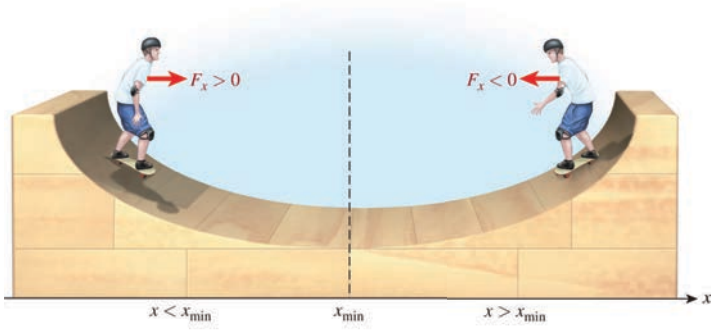

FIGURE 6.8 Skateboarder in a half-pipe.

In addition, we can reach this same conclusion mathematically, by writing a Taylor expansion for $F_x(x)$ around x_{min}:

$$F_x(x) = F_x(x_{min}) + \left(\frac{dF_x}{dx}\right)_{x=x_{min}} \cdot (x - x_{min}) + \frac{1}{2}\left(\frac{d^2F_x}{dx^2}\right)_a$$

Since we are expanding around the potential energy minimum and since we have just shown that the force is zero there, we have $F_x(x_{min}) = 0$. If there is a potential minimum at $x = x_{min}$, then the second derivative of the potential must be positive. Since, according to equation 6.14, the force is $F_x(x) = -dU(x)/dx$, this means that the derivative of the force is $dF_x(x)/dx = -d^2U(x)/dx^2$. At the minimum of the potential, we thus have $(dF_x/dx)_{x=x_{min}} < 0$. Expressing the value of the first derivative of the force at coordinate x_{min} as some constant, $(dF_x/dx)_{x=x_{min}} = -k$ (with $k > 0$), we find $F_x(x) = -k(x - x_{min})$, if we are sufficiently close to x_{min} that we can neglect terms proportional to $(x - x_{min})^2$ and higher powers.

These physical and mathematical arguments establish why it is important to study Hooke's Law and the resulting equations of motion in detail. In this chapter, we study the work done by the spring force. In Chapter 14 on oscillations, we will analyze the motion of an object under the influence of the spring force.

Self-Test Opportunity 6.1

Some forces in nature are proportional to the inverse of the distance between objects squared. How does the potential energy associated with such a force depend on the distance between the objects?

6.5 Conservation of Mechanical Energy

We have defined potential energy in reference to a system of objects. We will examine different kinds of general systems in later chapters, but here we focus on one particular kind of system: an **isolated system**, which by definition is a system of objects that exert forces on one another but for which no force external to the system causes energy changes within the system. This means that no energy is transferred into or out of the system. This very common situation is highly important in science and engineering and has been extensively studied. One of the fundamental concepts of physics involves energy within an isolated system.

To investigate this concept, we begin with a definition of **mechanical energy**, *E,* as the sum of kinetic energy and potential energy:

$$E = K + U. \tag{6.17}$$

(Later, when we move beyond mechanics, we will add other kinds of energy to this sum and call it the *total energy*.)

For any mechanical process that occurs inside an isolated system and involves only conservative forces, the total mechanical energy is conserved. This means that the total mechanical energy remains constant in time:

$$\Delta E = \Delta K + \Delta U = 0. \tag{6.18}$$

An alternative way of writing this result (which we'll derive below) is

$$K + U = K_0 + U_0, \tag{6.19}$$

where K_0 and U_0 are the initial kinetic energy and potential energy, respectively. This relationship, which is called the law of **conservation of mechanical energy**, does not imply that the kinetic energy of the system cannot change, or that the potential energy alone remains constant. Rather it states that their changes are exactly compensating and thus offset each other. It is worth repeating that conservation of mechanical energy is valid only for conservative forces and for an isolated system, for which the influence of external forces can be neglected.

DERIVATION 6.1

As we have already seen in equation 6.7, if a conservative force does work, then the work causes a change in potential energy:

$$\Delta U = -W.$$

(If the force under consideration is not conservative, this relationship does not hold in general, and conservation of mechanical energy is not valid.)

In Chapter 5, we learned that the relationship between the change in kinetic energy and the work done by a force is (equation 5.7):

$$\Delta K = W.$$

Combining these two results, we obtain

$$\Delta U = -\Delta K \Rightarrow \Delta U + \Delta K = 0.$$

Using $\Delta U = U - U_0$ and $\Delta K = K - K_0$, we find

$$0 = \Delta U + \Delta K = U - U_0 + K - K_0 = U + K - (U_0 + K_0$$
$$U + K = U_0 + K_0.$$

Note that Derivation 6.1 did not make any reference to the particular path along which the force did the work that caused the rearrangement. In fact, you do not need to know any detail about the work or the force, other than that the force is conservative. Nor do you need to know how many conservative forces are acting. If more than one conservative force is present, you interpret ΔU as the sum of all the potential energy changes and W as the total work done by all of the conservative forces, and the derivation is still valid.

The law of energy conservation enables us to easily solve a huge number of problems that involve only conservative forces, problems that would have been very hard to solve without this law. Later in this chapter, the more general work-energy theorem for mechanics, which includes nonconservative forces, will be presented. This law will enable us to solve an even wider range of problems, including those involving friction.

Equation 6.19 introduces our first conservation law, the law of conservation of mechanical energy. Chapters 18 and 20 will extend this law to include thermal energy (heat) as well. Chapter 7 will present a conservation law for linear momentum. When we discuss rotation in Chapter 10, we will encounter a conservation law for angular momentum. In studying electricity and magnetism, we will find a conservation law for net charge (Chapter 21), and in looking at elementary particle physics (Chapter 39), we will find conservation laws for several other quantities. This list is intended to give you a flavor of a central theme of physics—the discovery of conservation laws and their use in determining the dynamics of various systems.

Before we solve a sample problem, one more remark on the concept of an isolated system is in order. In situations that involve the motion of objects under the influence of the Earth's gravitational force, the isolated system to which we apply the law of conservation of energy actually consists of the moving object plus the entire Earth. However, in using the approximation that the gravitational force is a constant, we assume that the Earth is infinitely massive and thus immobile (and that the moving object is close to the surface of Earth). Therefore, no change in the kinetic energy of the Earth can result from the rearrangement of the system. Thus, we calculate all changes in kinetic energy and potential energy only for the "junior partner"—the object moving under the influence of the gravitational force. This force is conservative and internal to the system consisting

of Earth plus moving object, so all the conditions for the utilization of the law of energy conservation are fulfilled.

Specific examples of situations that involve objects moving under the influence of the gravitational force are projectile motion and pendulum motion occurring near the Earth's surface.

SOLVED PROBLEM 6.2 The Catapult Defense

Your task is to defend Neuschwanstein Castle from attackers (Figure 6.9). You have a catapult with which you can lob a rock with a launch speed of 14.2 m/s from the courtyard over the castle walls onto the attackers' camp in front of the castle at an elevation 7.20 m below that of the courtyard.

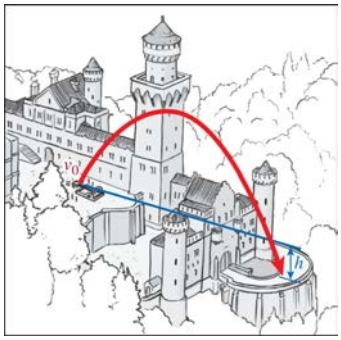

FIGURE 6.9 Illustration for a possible projectile path (red parabola) from the courtyard to the camp below and in front of the castle gate. The blue line indicates the horizontal.

PROBLEM

What is the speed with which a rock will hit the ground at the attackers' camp? (Neglect air resistance.)

SOLUTION

THINK

We can solve this problem by applying the conservation of mechanical energy. Once the catapult launches a rock, only the conservative force of gravity is acting on the rock. Thus, the total

mechanical energy is conserved, which means the sum of the kinetic and potential energies of the rock always equals the total mechanical energy.

SKETCH

The trajectory of the rock is shown in Figure 6.10, where the initial speed of the rock is v_0, the initial kinetic energy K_0, the initial potential energy U_0, and the initial height y_0. The final speed is v, the final kinetic energy K, the final potential energy U, and the final height y.

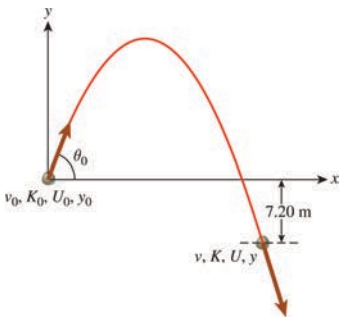

FIGURE 6.10
Trajectory of the rock launched by the catapult.

RESEARCH

We can use conservation of mechanical energy to write

$$E = K + U = K_0 + U_0,$$

where E is the total mechanical energy. The kinetic energy of the projectile can be expressed as

$$K = \frac{1}{2}mv^2,$$

where m is the mass of the projectile and v is its speed when it hits the ground. The potential energy of the projectile can be expressed as

$$U = mgy,$$

where y is the vertical component of the position vector of the projectile when it hits the ground.

SIMPLIFY

We substitute for K and U in $E = K + U$ to get

$$E = \frac{1}{2}mv^2 + mgy = \frac{1}{2}mv_0^2 + mgy_0.$$

The mass of the rock, m, cancels out, and we are left with

$$\frac{1}{2}v^2 + gy = \frac{1}{2}v_0^2 + gy_0.$$

We solve this for the speed:

$$v = \sqrt{v_0^2 + 2g(y_0 - y)}. \qquad \textbf{(6.20)}$$

CALCULATE

According to the problem statement, $y_0 - y = 7.20\ \text{m}$ and $v_0 = 14.2\ \text{m/s}$. Thus, for the final speed, we find

$$v = \sqrt{(14.2\ \text{m/s})^2 + 2(9.81\ \text{m/s})^2(7.20\ \text{m})} = 18.5176672$$

ROUND

The relative height was given to three significant figures, so we report our final answer as

$$v = 18.5\ \text{m/s}.$$

DOUBLE-CHECK

Our answer for the speed of the rock when it hits the ground in front of the castle is 18.5 m/s, compared with the initial launch speed of 14.2 m/s, which seems reasonable. This speed has to be bigger due to the gain from the difference in gravitational potential energy, and it is comforting that our answer passes this simple test.

Because we were only interested in the speed at impact, we did not even need to know the initial launch angle θ_0 to solve the problem. All launch angles will give the same result (for a given launch speed), which is a somewhat surprising finding. (Of course, if you were in this situation, you would obviously want to aim high enough to clear the castle wall and accurately enough to strike the attackers' camp.)

We can also solve this problem using the concepts of projectile motion, which is a way to double-check our answer and to show the power of applying the concept of energy conservation. We start by writing the components of the initial velocity vector $\overrightarrow{v_0}$:

$$v_{x0} = v_0 \cos \theta_0$$

and

$$v_{y0} = v_0 \sin \theta_0.$$

The final x-component of the velocity, v_x, is equal to the initial x-component of the initial velocity v_{x0},

$$v_x = v_{x0} = v_0 \ \cos \ \theta_0.$$

The final component of the velocity in the y-direction can be obtained from a result of the analysis of projectile motion in Chapter 3:

$$v_y^2 = v_{y0}^2 - 2g(y - y_0).$$

Therefore, the final speed of the rock as it hits the ground is

$$\begin{aligned} v &= \sqrt{v_x^2 + v_y^2} \\ &= \sqrt{(v_0 \cos\theta_0)^2 + \left(v_{y0}^2 - 2g(y - y_0)\right)} \\ &= \sqrt{v_0^2 \cos^2\theta_0 + v_0^2 \sin^2\theta_0 - -2g(y - y_0)}. \end{aligned}$$

Remembering that $\sin^2\theta + \cos^2\theta = 1$, we can further simplify and get:

$$v = \sqrt{v_0^2\left(\cos^2\theta_0 + \sin^2\theta_0\right) - 2g(y - y_0)} = \sqrt{v_0^2 - 2g(y -}$$

This is the same as equation 6.20, which we obtained using energy conservation. Even though the final result is the same, the solution process based on energy conservation was by far easier than that based on kinematics.

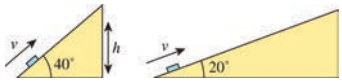
Self-Test Opportunity 6.2

In Solved Problem 6.2, we neglected air resistance. Discuss qualitatively how our final answer would have changed if we had included the effects of air resistance.

As you can see from Solved Problem 6.2, applying the conservation of mechanical energy provides us with a powerful technique for solving problems that seem rather complicated at first sight.

Concept Check 6.3

A block is launched up a frictionless 40° slope with an initial speed v and reaches a maximum vertical height h as shown.



The same block is launched up a frictionless 20° slope with the same initial speed v. On this slope, the block reaches a maximum vertical height of

a) $h/2$.

b) h.

c) $2/h$.

d) a height greater than h but less than $2h$.

e) a height greater than $h/2$ but less than h.

In general, we can determine final speed as a function of the elevation in situations where the gravitational force is at work. For instance, consider the image sequence in Figure 6.11. Two balls are released at the same time from the same height at the top of two ramps with different shapes. At the bottom end of the ramps, both balls reach the same lower elevation. Therefore, in both cases, the height difference between the initial and final points is the same. Both balls also experience normal forces in addition to the gravitational force; however, the normal forces do no work because they are perpendicular to the contact surface, by definition, and the motion is parallel to the surface. Thus, the scalar product of the normal force and displacement vectors is zero. (There is a small friction force, but it is negligible in this case.) Energy conservation considerations (see equation 6.20 in Solved Problem 6.2) tell us that the speed of both balls at the bottom end of the ramps has to be the same:

$$v = \sqrt{2g(y_0 - y)}.$$

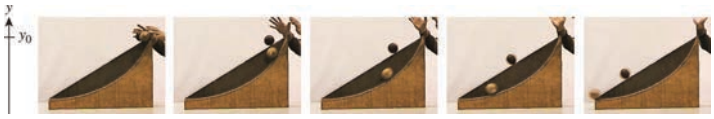


FIGURE 6.11 Race of two balls down different inclines of the same height.

W. Bauer and G. D. Westfall

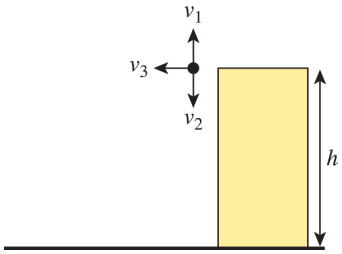
This equation is a special case of equation 6.20 with $v_0 = 0$. Note that, depending on the curve of the bottom ramp, this result could be rather difficult to obtain using Newton's Second Law. However, even though the velocities at the top and the bottom of the ramps are the same for both balls, you cannot conclude from this result that both balls arrive at the bottom at the same time. The image sequence clearly shows that this is not the case.

Self-Test Opportunity 6.3

Why does the lighter-colored ball arrive at the bottom in Figure 6.11 before the other ball?

Concept Check 6.4

Three balls of equal mass are fired simultaneously with equal speeds from the same height, *h,* above the ground as shown.



McGraw Hill

Ball 1 is fired straight up, ball 2 is fired straight down, and ball 3 is fired horizontally. Rank in order from largest to smallest their speeds, v_1, v_2, and v_3, at the instant right before they hit the ground. (You should neglect friction.)

a) $v_1 = v_2 = v_3$

b) $v_2 > v_3 > v_1$

c) $v_3 > v_2 > v_1$

d) $v_2 > v_1 > v_3$

e) $v_1 = v_2 > v_3$

SOLVED PROBLEM 6.3 Trapeze Artist

PROBLEM

A circus trapeze artist starts her motion with the trapeze at rest at an angle of 45.0° relative to the vertical. The trapeze ropes have a length of 5.00 m. What is her speed at the lowest point in her trajectory?

SOLUTION

THINK

Initially, the trapeze artist has only gravitational potential energy. We can choose a coordinate system such that $y = 0$ is at her trajectory's lowest point, so the potential energy is zero at that lowest point. When the trapeze artist is at the lowest point, her kinetic energy will be a maximum. We can then equate the initial gravitational potential energy to the final kinetic energy of the trapeze artist.

SKETCH

We represent the trapeze artist in Figure 6.12 as an object of mass m suspended by a rope of length ℓ. We indicate the position of the trapeze artist at a given value of the angle θ by the blue disk. The lowest point of the trajectory is reached at $\theta = 0$, and we indicate this in Figure 6.12 by a gray disk.

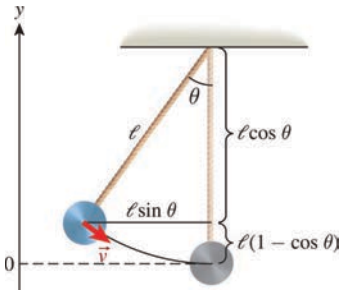


FIGURE 6.12 Geometry of a trapeze artist's swing or trajectory.

The figure shows that the trapeze artist is at a distance *l* (the length of the rope) below the ceiling at the lowest point and at a distance $\ell \cos \theta$ below the ceiling for all other values of θ. This means that she is at a height $h = \ell - \ell \cos \theta = \ell(1 - \cos \theta)$ above the lowest point in the trajectory when the trapeze forms an angle θ with the vertical.

RESEARCH

The trapeze is pulled back to an initial angle θ_0 relative to the vertical, and thus the trapeze artist is at a height $h = \ell(1 - \cos \theta_o)$ above the lowest point in the trajectory, according to our analysis of Figure 6.12. The potential energy at this maximum deflection, θ_o, is therefore

$$E = K + U = 0 + U = mg\ell(1 - \cos \theta_0).$$

This is also the value for the total mechanical energy, because the trapeze artist has zero kinetic energy at the point of maximum deflection. For any other deflection, the energy is the sum of kinetic and potential energies:

$$E = mg\ell(1 - \cos \theta) + \frac{1}{2}mv^2.$$

SIMPLIFY

Solving the preceding equation for the speed, we obtain

$$\begin{gathered} mg\ell\left(1 - \cos \theta_0\right) = mg\ell\left(1 - \cos \theta\right) + \tfrac{1}{2}mv^2 \Rightarrow \\ mg\ell\ \left(\cos \theta - \cos \theta_0\right) = \tfrac{1}{2}mv^2 \Rightarrow \\ |v| = \sqrt{2g\ell(\cos \theta - \cos \theta_0)}. \end{gathered}$$

Here, we are interested in the speed for $|v(\theta = 0)|$, which is

$$|v(\theta = 0)| = \sqrt{2g\ell(\cos\ 0 - \cos \theta_0\ )} = \sqrt{2g\ell(1 - \cos \theta_0)}.$$

CALCULATE

The initial condition is $\theta_0 = 45.0^\circ$. Inserting the numbers, we find

$$|v(0^\circ)| = \sqrt{2(9.81\ \text{m/s}^2)(5.00\ \text{m})(1-\cos\ 45.0^\circ)} = 5.36($$

ROUND

All of the numerical values were specified to three significant figures, so we report our answer as

$$|v(0^\circ)| = 5.36\ \text{m/s}.$$

DOUBLE-CHECK

First, the obvious check of units: m/s is the SI unit for velocity and speed. The speed of the trapeze artist at the lowest point is 5.36 m/s (12 mph), which seems in line with what we see in the circus.

We can perform another check on the formula $|v(\theta = 0)| = \sqrt{2g\ell(1 - \cos\theta_0)}$ by considering the limiting cases for the initial angle θ_0 to see if they yield reasonable results. In this situation, the limiting values for θ_0 are 90°, where the trapeze starts out horizontal, and 0°, where it starts out vertical. If we use $\theta_0 = 0$, the trapeze is just hanging at rest, and we expect zero speed, an expectation borne out by our formula. On the other hand, if we use $\theta_0 = 90^\circ$,or $\cos\theta_0 = \cos 90^\circ = 0$. we obtain the limiting result $\sqrt{2g\ell}$, which is the same result as a free fall from the ceiling to the bottom of the trapeze swing. Again, this limit is as expected, which gives us additional confidence in our solution.

6.6 Work and Energy for the Spring Force

In Section 6.3, we found that the potential energy stored in a spring is $U_s = \frac{1}{2}kx^2 +$ constant, where k is the spring constant and x is the displacement from the equilibrium position. Here we choose the additive constant to be zero, corresponding to having $U_s = 0$ at x = 0. Using the principle of energy conservation, we can find the velocity v as a function of the position. First, we can write, in general, for the total mechanical energy:

$$E = K + U_s = \frac{1}{2}mv^2 + \frac{1}{2}kx^2. \qquad \textbf{(6.21)}$$

Once we know the total mechanical energy, we can solve this equation for the velocity. What is the total mechanical energy? The point of maximum elongation of a spring from the equilibrium position is called the **amplitude**, A. When the displacement reaches the amplitude, the velocity is briefly zero. At this point, the total mechanical energy of an object oscillating on a spring is

$$E = \frac{1}{2}kA^2.$$

However, conservation of mechanical energy means that this is the value of the energy for any point in the spring's oscillation. Inserting the above expression for E into equation 6.21 yields

$$\frac{1}{2}kA^2 = \frac{1}{2}mv^2 + \frac{1}{2}kx^2. \qquad \textbf{(6.22)}$$

From equation 6.22, we can get an expression for the speed as a function of the position:

$$v = \sqrt{(A^2 - x^2)\frac{k}{m}}. \tag{6.23}$$

Note that we did not rely on kinematics to get this result, as that approach is rather challenging—another piece of evidence that using principles of conservation (in this case, conservation of mechanical energy) can yield powerful results. We will return to the equation of motion for a mass on a spring in Chapter 14.

SOLVED PROBLEM 6.4 Human Cannonball

In a favorite circus act, called the "human cannonball," a person is shot from a long barrel, usually with a lot of smoke and a loud bang added for theatrical effect. Before the Italian Zacchini brothers invented the compressed air cannon for shooting human cannonballs in the 1920s, the Englishman George Farini used a spring-loaded cannon for this purpose in the 1870s.

Suppose someone wants to recreate Farini's spring-loaded human cannonball act with a spring inside a barrel. Assume the barrel is 4.00 m long, with a spring that extends the entire length of the barrel. Further, the barrel is upright, so it points vertically toward the ceiling of the circus tent. The human cannonball is lowered into the barrel and compresses the spring to some degree. An external force is added to compress the spring even further, to a length of only 0.70 m. At a height of 7.50 m above the top of the barrel is a spot on the tent that the human cannonball, of height 1.75 m and mass 68.4 kg, is supposed to touch at the top of his trajectory. Removing the external force releases the spring and fires the human cannonball vertically upward.

PROBLEM 1

What is the value of the spring constant needed to accomplish this stunt?

SOLUTION 1

THINK

Let's apply energy conservation considerations to solve this problem. Potential energy is stored in the spring initially and then converted to gravitational potential energy at the top of the human cannonball's flight. As a reference point for our calculations, we select the top of the barrel and place the origin of our coordinate system there. To accomplish the stunt, enough energy has to be provided, through compressing the spring, that the top of the head of the human cannonball is elevated to a height of 7.50 m above the zero point we have chosen. Since the

person has a height of 1.75 m, his feet need to be elevated by only h = 7.50 m − 1.75 m = 5.75 m. We can specify all position values for the human cannonball on the y-coordinate as the position of the bottom of his feet.

SKETCH

To clarify this problem, let's apply energy conservation at different instants of time. Figure 6.13a shows the initial equilibrium position of the spring. In Figure 6.13b, the external force $\overrightarrow{F}$ and the weight of the human cannonball compress the spring by 3.30 m to a length of 0.70 m. When the spring is released, the cannonball accelerates and has a velocity $\overrightarrow{v_c}$ as he passes the spring's equilibrium position (see Figure 6.13c). From this position, he has to rise 5.75 m and arrive at the spot (Figure 6.13e) with zero velocity.

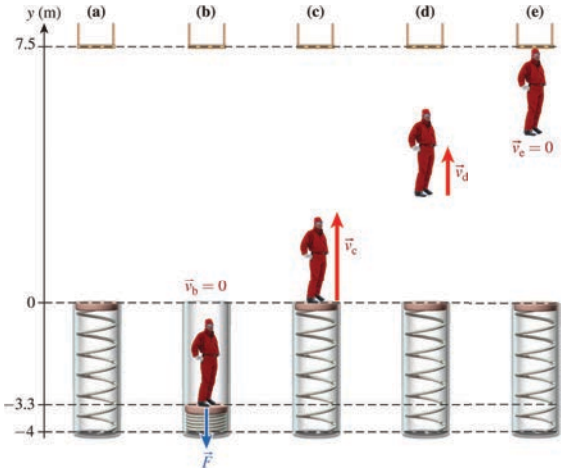

FIGURE 6.13 The human cannonball stunt at five different instants of time.

W. Bauer and G. D. Westfall

RESEARCH

We are free to choose the zero point for the gravitational potential energy arbitrarily. We elect to set the gravitational

potential to zero at the equilibrium position of the spring without a load, as shown in Figure 6.13a.

At the instant depicted in Figure 6.13b, the human cannonball has zero kinetic energy and potential energies from the spring force and gravity. Therefore, the total energy at this instant is

$$E = \frac{1}{2}ky_{\mathrm{b}}^2 + mgy_{\mathrm{b}}.$$

At the instant shown in Figure 6.13c, the human cannonball has only kinetic energy and zero potential energy:

$$E = \frac{1}{2}mv_{\mathrm{c}}^2.$$

Right after this instant, the human cannonball leaves the spring, flies through the air as shown in Figure 6.13d, and finally reaches the top(Figure 6.13e). At the top, he has only gravitational potential energy and no kinetic energy (because the spring is designed to allow him to reach the top with no residual speed):

$$E = mgy_{\mathrm{e}}.$$

SIMPLIFY

Energy conservation requires that the total energy remain the same. Setting the first and third expressions written above for E equal, we obtain

$$\frac{1}{2}ky_{\mathrm{b}}^2 + mgy_{\mathrm{b}} = mgy_{\mathrm{e}}.$$

We can rearrange this equation to obtain the spring constant:

$$k = 2mg\frac{y_{\mathrm{e}} - y_{\mathrm{b}}}{y_{\mathrm{b}}^2}.$$

CALCULATE

According to the given information and the origin of the coordinate system we selected, $y_b = -3.30$ m and $y_e = 5.75$ m. Thus, we find that the necessary value of the spring constant is

$$k = 2(68.4\text{ kg})\left(9.81\text{ m/s}^2\right)\frac{5.75\text{ m} - (-3.30\text{ m})}{(3.30\text{ m})^2} = 1115.2$$

ROUND

All of the numerical values used in the calculation have three significant figures, so our final answer is

$$k = 1.12 \cdot 10^3\text{ N/m}.$$

DOUBLE-CHECK

When the spring is compressed initially, the potential energy stored in it is

$$U = \frac{1}{2}ky_b^2 = \frac{1}{2}\left(1.12 \cdot 10^3\text{ N/m}\right)(3.30\text{ m})^2 = 6.07\text{ kJ}.$$

The gravitational potential energy gained by the human cannonball is

$$U = mg\Delta y = (68.4\text{ kg})\left(9.81\text{ m/s}^2\right)(9.05\text{ m}) = 6.07\text{ kJ},$$

which is the same as the energy stored in the spring initially. Our calculated value for the spring constant makes sense.

Note that the mass of the human cannonball enters into the equation for the spring constant. We can turn this around and state that the same cannon with the same spring will shoot people of different masses to different heights.

PROBLEM 2

What is the speed that the human cannonball reaches as he passes the equilibrium position of the spring?

SOLUTION 2

We have already determined that our choice of origin implies that at this instant the human cannonball has only kinetic energy. Setting this kinetic energy equal to the potential energy reached at the top, we find

$$\frac{1}{2}mv_{\mathrm{c}}^2 = mgy_{\mathrm{e}} \Rightarrow$$

$$v_{\mathrm{c}} = \sqrt{2gy_{\mathrm{e}}} = \sqrt{2\left(9.81\ \mathrm{m/s^2}\right)(5.75\ \mathrm{m})} = 10.6\ \mathrm{m/s}.$$

This speed corresponds to 23.8 mph.

Concept Check 6.5

A spring with spring constant *k* is oriented vertically and compressed downward a distance *x* from its equilibrium position. An object of mass *m* is placed on the upper end of the spring, and the spring is released. The object rises a distance *h* (with $h \gg x$) above the equilibrium position of the spring. If the spring is then compressed downward by the same distance *x* and an object of mass 3*m* is placed on it, how high will the object rise when the spring is released?

a) h

b) $3h$

c) $3/h$

d) h^3

e) $h^{1/2}$

Concept Check 6.6

A ball of mass, *m,* is thrown vertically into the air with an initial speed, *v*. Which of the following equations correctly describes the maximum height, *h,* of the ball?

a) $h = \sqrt{\frac{v}{2g}}$

b) $h = \frac{g}{\frac{1}{2}v^2}$

c) $h = \frac{2mv}{g}$

d) $h = \frac{mv^2}{g}$

e) $h = \frac{v^2}{2g}$

Self-Test Opportunity 6.4

Graph the potential and kinetic energies of the human cannonball of Solved Problem 6.4 as a function of the *y*-coordinate. For what value of the displacement is the speed of the human cannonball at a maximum? (*Hint:* This occurs not exactly at $y = 0$ but at a value of $y < 0$.)

EXAMPLE 6.3 Bungee Jumper

A bungee jumper locates a suitable bridge that is 75.0 m above the river below, as shown in Figure 6.14. The jumper has a mass of m = 80.0 kg and a height of $L_{\text{jumper}} = 1.85$ m. We can think of a bungee cord as a spring. The spring constant of the bungee cord is k = 50.0 N/m. Assume that the mass of the bungee cord is negligible compared with the jumper's mass.

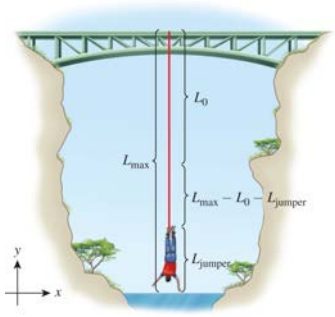

FIGURE 6.14 A bungee jumper needs to calculate how long a bungee cord he can safely use.

PROBLEM

The jumper wants to know the maximum length of bungee cord he can safely use for this jump.

SOLUTION

We are looking for the unstretched length of the bungee cord, L_0, as the jumper would measure it standing on the bridge. The distance from the bridge to the water is $L_{\text{max}} = 75.0$ m. Energy conservation tells us that the gravitational potential energy that the jumper has, as he dives off the bridge, will be converted to potential energy stored in the bungee cord. The jumper's gravitational potential energy on the bridge is

$$U_{\text{g}} = mgy = mgL_{\text{max}},$$

assuming that gravitational potential energy is zero at the level of the water. Before he starts his jump, he has zero kinetic energy, and so his total energy when he is on top of the bridge is

$$E_{\text{top}} = mgL_{\text{max}}.$$

At the bottom of the jump, where the jumper's head just touches the water, the potential energy stored in the bungee cord is

$$U_{\text{s}} = \frac{1}{2}ky^2 = \frac{1}{2}k(L_{\text{max}} - L_{\text{jumper}} - L_0)^2,$$

where $L_{\text{max}} - L_{\text{jumper}} - L_0$ is the length that the bungee cord stretches beyond its unstretched length. (Here we have to subtract the jumper's height from the height of the bridge to obtain the maximum length, $L_{\text{max}} - L_{\text{jumper}}$, to which the bungee cord is allowed to stretch, assuming that it is tied around his ankles.) Since the bungee jumper is momentarily at rest at this lowest point of his jump, the kinetic energy is zero at that point, and the total energy is then

$$E_{\text{bottom}} = \frac{1}{2}k(L_{\text{max}} - L_{\text{jumper}} - L_0)^2.$$

From the conservation of mechanical energy, we know that $E_{\text{top}} - E_{\text{bottom}}$, and so we find

$$mgL_{\text{max}} = \frac{1}{2}k(L_{\text{max}} - L_{\text{jumper}} - L_0)^2.$$

Solving for the required unstretched length of bungee cord gives us

$$L_0 = L_{\text{max}} - L_{\text{jumper}} - \sqrt{\frac{2mgL_{\text{max}}}{K}}.$$

Putting in the given numbers, we get

$$L_0 = (75.0\ \text{m}) - (1.85\ \text{m}) - \sqrt{\frac{2(80.0\ \text{kg})\left(9.81\ \text{m/s}^2\right)(75}{50.0\ \text{N/m}}}$$

For safety, the jumper would be wise to use a bungee cord shorter than this and to test it with a dummy mass similar to his.

Concept Check 6.7

At the moment of maximum stretching of the bungee cord in Example 6.3, what is the net acceleration that the jumper experiences (in terms of g = 9.81 m/s^2)?

a) 0g

b) 1.0g, directed downward

c) 1.0g, directed upward

d) 2.1g, directed downward

e) 2.1g, directed upward

Self-Test Opportunity 6.5

Can you derive an expression for the acceleration that the bungee jumper experiences at the maximum stretching of the bungee cord? How does this acceleration depend on the spring constant of the bungee cord?

Potential Energy of an Object Hanging from a Spring

We saw in Solved Problem 6.4 that the initial potential energy of the human cannonball has contributions from the spring force and the gravitational force. In Example 5.3 and the discussion following it, we established that hanging an object of mass m from a spring with spring constant k shifts the equilibrium position of the spring from zero to y_0, given by the equilibrium condition,

$$ky_0 = -mg \Rightarrow y_0 = -\frac{mg}{k}. \qquad \textbf{(6.24)}$$

Figure 6.15 shows the forces that act on an object suspended from a spring when it is in different positions. This figure shows two different choices for the origin of the vertical coordinate axis: In Figure 6.15a, the vertical coordinate is called y and has zero at the equilibrium position of the end of the spring without the mass hanging from it; in Figure 6.15b the new equilibrium point, y_0, with the object suspended from the spring, is calculated according to equation 6.24. This new equilibrium point is the origin of the axis and the vertical coordinate is called s. The end of the spring is located at s = 0. The system is in equilibrium because the force exerted by the spring on the object balances the gravitational force acting on the object:

$$\overrightarrow{F}_s(y_0) + \overrightarrow{F}_{\text{g}} = 0.$$

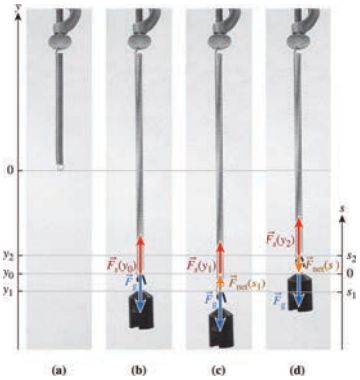

FIGURE 6.15 (a) A spring is hanging vertically with its end in the equilibrium position at $y = 0$. (b) An object of mass m is hanging at rest from the same spring, with the end of the spring now at $y = y_0$ or $s = 0$. (c) The end of the spring with the object attached is at $y = y_1$ or $s = s_1$. (d) The end of the spring with the object attached is at $y = y_2$ or $s = s_2$.

W. Bauer and G. D. Westfall

In Figure 6.15c, the object has been displaced downward away from the new equilibrium position, so $y = y_1$ and $s = s_1$. Now there is a net upward force tending to restore the object to the new equilibrium position:

$$\overrightarrow{F}_{\text{net}}(s_1) + \overrightarrow{F}_s(y_1) + \overrightarrow{F}_{\text{g}}.$$

If instead, the object is displaced upward, above the new equilibrium position, as shown in Figure 6.15d, there is a net downward force that tends to restore the object to the new equilibrium position:

$$\overrightarrow{F}_{\text{net}}(s_2) + \overrightarrow{F}_{\text{s}}(y_2) + \overrightarrow{F}_{\text{g}}.$$

We can calculate the potential energy of the object and the spring for these two choices of the coordinate system and show that they differ by only a constant. We start by defining the potential energy of the object connected to the spring, taking y as the variable and assuming that the potential energy is zero at y = 0:

$$U(y) = \frac{1}{2}ky^2 + mgy.$$

Using the relation $y = s + y_0$, we can express this potential energy in terms of the variable s:

$$U(s) = \frac{1}{2}k(s + y_0)^2 + mg(s + y_0).$$

Rearranging gives us

$$U(s) = \frac{1}{2}ks^2 + ksy_0 + \frac{1}{2}ky_0^2 + mgs + mgy_0.$$

Substituting $ky_0 = -mg$ from equation 6.24, into this equation, we get

$$U(s) = \frac{1}{2}ks^2 - (mg)s + \frac{1}{2}(mg)y_0 + mgs - mgy_0.$$

Thus, we find that the potential energy in terms of s is

$$U(s) = \frac{1}{2}ks^2 - \frac{1}{2}mgy_0. \qquad \textbf{(6.25)}$$

Figure 6.16 shows the potential energy functions for these two coordinate axes. The blue curve in Figure 6.16 (a) shows the potential energy as a function of the vertical coordinate y, with the choice of zero potential energy at y = 0 corresponding to the spring hanging vertically without the object connected to it. The new equilibrium position, y_0, is determined by the displacement that occurs when an object of mass m is attached to the spring, as calculated using equation 6.24. The red curve in Figure 6.16 (b) represents the potential energy as a function of the vertical coordinate s, with the equilibrium position chosen to be s = 0. The potential energy curves $U(y)$ and $U(s)$ are both parabolas, which are offset from each other by a simple constant.

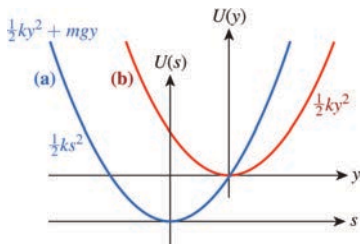

FIGURE 6.16
Potential energy functions for the two vertical coordinate axes used in Figure 6.15.

Thus, we can express the potential energy of an object of mass m hanging from a vertical spring in terms of the displacement s about an equilibrium point as

$$U(s) = \frac{1}{2}ks^2 + C,$$

where C is a constant. For many problems, we can choose zero as the value of this constant, allowing us to write

$$U(s) = \frac{1}{2}ks^2.$$

This result allows us to use the same spring force potential for different masses attached to the end of a spring by simply shifting the origin to the new equilibrium position. (Of course, this only works if we do not attach too much mass to the end of the spring and overstretch it beyond its elastic limit.)

6.7 Nonconservative Forces and the Work-Energy Theorem

With the introduction of the potential energy we can extend and augment the work–kinetic energy theorem of Chapter 5 for conservative forces. By including the potential energy as well, we find the **work-energy theorem**

$$W = \Delta E = \Delta K + \Delta U \qquad \textbf{(6.26)}$$

where W is the work done by an *external* force, ΔK is the change of kinetic energy, and ΔU is the change in potential energy. This relationship means that external work done to a system can change the total energy of the system.

Is energy conservation violated in the presence of nonconservative forces? The word *nonconservative* seems to imply that it is violated, and, indeed, the total *mechanical* energy is not conserved. Where, then, does the energy go? Section 6.2 showed that the friction force does not do work but instead dissipates mechanical energy into internal excitation energy, which can be vibration energy, deformation energy, chemical energy, or electrical energy, depending on the material of which the object is made and on the particular form of the friction force. In Section 6.2, we found that W_{f} is the total energy dissipated by nonconservative forces into internal energy and then into other energy forms besides mechanical energy. If we add this type of energy to the total mechanical energy, we obtain the **total energy**:

$$E_{\text{total}} = E_{\text{mechanical}} + E_{\text{other}} = K + U + E_{\text{other}}. \qquad \textbf{(6.27)}$$

Here E_{other} stands for all other forms of energy that are not kinetic or potential energies. The change in the other energy forms is exactly

the negative of the energy dissipated by the friction force in going from the initial to the final state of the system:

$$\Delta E_{\text{other}} = -W_{\text{f}}.$$

The total energy is conserved—that is, stays constant in time—even for nonconservative forces. This is the most important point in this chapter:

> **The total energy—the sum of all forms of energy, mechanical or other—is *always* conserved in an isolated system.**

We can also write this law of energy conservation in the form that states that the change in the total energy of an isolated system is zero:

$$\Delta E_{\text{total}} = 0. \qquad \textbf{(6.28)}$$

Since we do not yet know what exactly this internal energy is and how to calculate it, it may seem that we cannot use energy considerations when at least one of the forces acting is nonconservative. However, this is not the case. For the case in which only conservative forces are acting, we found that (see equation 6.18) the total mechanical energy is conserved, or $\Delta E = \Delta K + \Delta U = 0$, where E refers to the total mechanical energy. In the presence of nonconservative forces, combining equations 6.28, 6.27, and 6.26 gives

$$W_{\text{f}} = \Delta K + \Delta U. \qquad \textbf{(6.29)}$$

This relationship is a generalization of the work-energy theorem. In the absence of nonconservative forces, $W_{\text{f}} = 0$, and equation 6.29 reduces to the law of the conservation of mechanical energy,

equation 6.19. When applying either of these two equations, you must select two times—a beginning and an end. Usually this choice is obvious, but sometimes care must be taken, as demonstrated in the following solved problem.

SOLVED PROBLEM 6.5 Block Pushed Off a Table

Consider a block on a table. This block is pushed by a spring attached to the wall, slides across the table, and then falls to the ground. The block has a mass m = 1.35 kg. The spring constant is k = 560. N/m, and the spring is initially compressed by 0.110 m. The block slides a distance d = 0.65 m across the table of height h = 0.750 m. The coefficient of kinetic friction between the block and the table is $\mu_k = 0.160$.

PROBLEM

What speed will the block have when it lands on the floor?

SOLUTION

THINK

At first sight, this problem does not seem to be one to which we can apply mechanical energy conservation, because the nonconservative force of friction is in play. However, we can utilize the work-energy theorem, equation 6.29. To be certain that the block actually leaves the table, though, we first calculate the total energy imparted to the block by the spring and make sure that the potential energy stored in the compressed spring is sufficient to overcome the friction force.

SKETCH

Figure 6.17a shows the block of mass m pushed by the spring. The mass slides on the table a distance d and then falls to the floor, which is a distance h below the table.

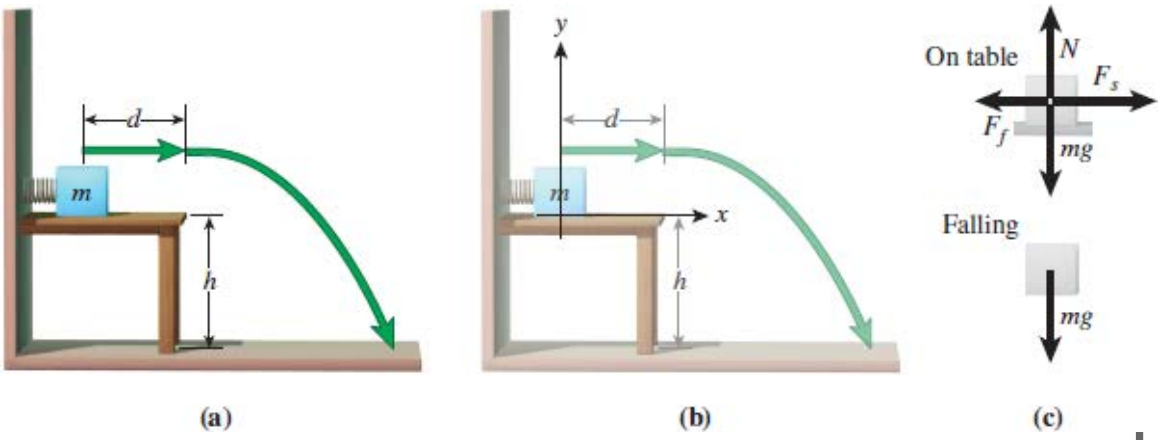

FIGURE 6.17 (a) Block of mass m is pushed off a table by a spring. (b) A coordinate system is superimposed on the block and table. (c) Free-body diagrams of the block while moving on the table and while falling.

We choose the origin of our coordinate system such that the block starts at $x = y = 0$, with the x-axis running along the bottom surface of the block and the y-axis running through its center (Figure 6.17b). The origin of the coordinate system can be placed at any point, but it is important to fix an origin, because all potential energies have to be expressed relative to some reference point.

RESEARCH

Step 1: Let's analyze the problem situation without the friction force. In this case, the block initially has potential energy from the spring and no kinetic energy, since it is at rest. When the block hits the floor, it has kinetic energy and negative gravitational potential energy. Conservation of mechanical energy results in

$$K_0 + U_0 = K + U \Rightarrow$$
$$0 + \frac{1}{2}kx_0^2 = \frac{1}{2}mv^2 - mgh. \qquad \textbf{(i)}$$

Usually, we would solve this equation for the speed and put in the numbers later. However, because we will need them again, let's evaluate the two expressions for potential energy:

$$\frac{1}{2}kx_0^2 = 0.5(560\ \text{N/m})(0.11\ \text{m})^2 = 3.39\ \text{J}$$

$$mgh = (1.35\ \text{kg})\left(9.81\ \text{m/s}^2\right)(0.75\ \text{m}) = 9.93\ \text{J}.$$

Now, solving equation (i) for the speed results in

$$v = \sqrt{\frac{2}{m}\left(\frac{1}{2}kx_0^2 + mgh\right)} = \sqrt{\frac{2}{1.35\ \text{kg}}(3.39\ \text{J} + 9.93\ \text{J})} =$$

Step 2: Now we include friction. Our considerations remain almost unchanged, except that we have to include the energy dissipated by the nonconservative force of friction. We find the force of friction using the upper free-body diagram in Figure 6.17c. We can see that the normal force is equal to the weight of the block and write

$$N = mg.$$

The friction force is given by

$$F_\text{k} = \mu_\text{k} N = \mu_\text{k} mg.$$

We can then write the energy dissipated by the friction force as

$$W_\text{f} = -\mu_\text{k} mgd.$$

In applying the generalization of the work-energy theorem, we choose the initial time to be when the block is about to start moving (see Figure 6.17a) and the final time to be when the block reaches the edge of the table and is about to start the free-fall portion of its path. Let K_top be the kinetic energy at the final time, chosen to make sure that the block makes it to the end of the table. Using equation 6.29 and the value we calculated above for the block's initial potential energy, we find:

$$W_{\mathrm{f}} = \Delta K + \Delta U = K_{\mathrm{top}} - \frac{1}{2}kx_0^2 = -\mu_{\mathrm{k}}mgd.$$

$$\begin{aligned} K_{\mathrm{top}} &= \frac{1}{2}kx_0^2 - \mu_{\mathrm{k}}mgd \\ &= 3.39\text{ J-}(0.16)(1.35\text{ kg})\left(9.81\text{ m/s}^2\right)(0.65\text{ m}) \\ &= 3.39\text{ J-}1.38\text{ J} = 2.01\text{ J}. \end{aligned}$$

Because the kinetic energy $K_{\mathrm{top}} > 0$, the block can overcome friction and slide off the table. Now we can calculate the block's speed when it hits the floor.

SIMPLIFY

For this part of the problem, we choose the initial time to be when the block is at the table's edge to exploit the calculations we have already done. The final time is when the block hits the floor. (If we chose the beginning to be as shown in Figure 6.17a, our result would be the same.)

Page 181

$$\begin{aligned} W_{\mathrm{f}} &= \Delta K + \Delta U = 0 \\ \frac{1}{2}mv^2 &- K_{\mathrm{top}} + 0 - mgh = 0, \\ v &= \sqrt{\frac{2}{m}(K_{\mathrm{top}} + mgh)}. \end{aligned}$$

CALCULATE

Putting in the numerical values gives us

$$v = \sqrt{\frac{2}{1.35\text{ kg}}(2.01\text{ J} + 9.93\text{ J})} = 4.20581608\text{ m/s}.$$

ROUND

All of the numerical values were given to three significant figures, so we have

$$v = 4.21 \text{ m/s}.$$

DOUBLE-CHECK

As you can see, the main contribution to the speed of the block at impact originates from the free-fall portion of its path. Why did we go through the intermediate step of figuring out the value of K_{top}, instead of simply using the formula $v = \sqrt{2\left(\frac{1}{2}Kx_0^2 - \mu_{\text{k}}mgd + mgh\right)/m}$, which we got from a generalization of the work-energy theorem? We needed to calculate K_{top} first to ensure that it is positive, meaning that the energy imparted to the block by the spring is sufficient to exceed the work to be done against the friction force. If K_{top} had turned out to be negative, the block would have stopped on the table. For example, if we had attempted to solve the same problem with a coefficient of kinetic friction between the block and the table of $\mu_{\text{k}} = 0.50$ instead of $\mu_{\text{k}} = 0.16$, we would have found that

$$K_{\text{top}} = 3.39 \text{ J} - 4.30 \text{ J} = -0.91 \text{ J},$$

which is impossible.

Concept Check 6.8

A curling stone of mass m is given an initial velocity v on ice, where the coefficient of kinetic friction is μ_k. The stone travels a distance d. If the initial velocity is doubled, how far will the stone slide?

a) d

b) $2d$

c) d^2

d) $4d$

e) $4d^2$

As Solved Problem 6.5 shows, energy considerations are still a powerful tool for performing otherwise very difficult calculations, even in the presence of nonconservative forces. However, the principle of conservation of mechanical energy cannot be applied quite as straightforwardly when nonconservative forces are present, and you have to account for the energy dissipated by these forces. Let's try one more solved problem to elaborate on these concepts.

Concept Check 6.9

A sled with mass m initially has speed v and slides to a stop on a level surface with coefficient of kinetic friction μ_k after traveling a distance d. Which of the following expressions is correct for the initial speed?

a) $v = \sqrt{2\mu_k g d}$

b) $v = \sqrt{\mu_k m g d}$

c) $v = 2\mu_k g d / m$

d) $v = (1/2)\mu_k m g d^2$

e) $v = 2m/\sqrt{\mu_k d g}$

SOLVED PROBLEM 6.6 Sledding down a Hill

PROBLEM

A boy on a sled starts from rest and slides down a snow-covered hill. Together the boy and sled have a mass of 23.0 kg. The hill's slope makes an angle $\theta = 35.0^\circ$ with the horizontal. The surface of the hill is 25.0 m long. When the boy and the sled reach the bottom of the hill, they continue sliding on a horizontal snow-covered field. The coefficient of kinetic friction between the sled and the snow is 0.100. How far do the boy and sled move on the horizontal field before stopping?

SOLUTION

THINK

The boy and sled start with zero kinetic energy and finish with zero kinetic energy and have gravitational potential energy at the top of the hill. As boy and sled go down the hill, they gain kinetic energy. At the bottom of the hill, their potential energy is zero, and they have kinetic energy. However, the boy and sled are continuously losing energy to friction. Thus, the change in potential energy will equal the energy lost to friction. We must take into account the fact that the friction force will be different when the sled is on the slope than when it is on the flat field.

SKETCH

A sketch of the boy sledding is shown in Figure 6.18.

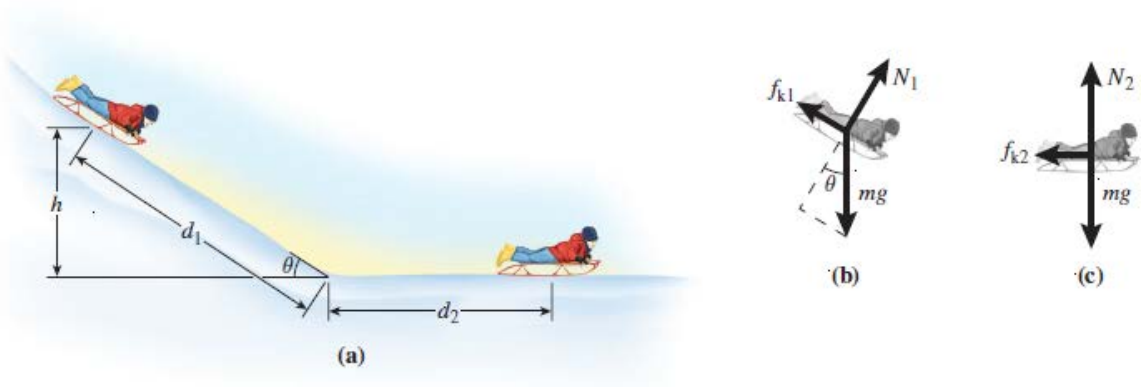

FIGURE 6.18 (a) Sketch of the boy and sled on the slope and on the flat field, showing the angle of incline and distances. (b) Free-body diagram for the boy and sled on the slope. (c) Free-body diagram for the boy and sled on the flat field.

RESEARCH

The boy and sled start with zero kinetic energy and finish with zero kinetic energy. We call the length of the slope of the hill d_1, and the distance that the boy and sled travel on the flat field d_2, as shown in Figure 6.18a. Assuming that the gravitational potential energy of the boy and sled is zero at the bottom of the hill, the change in the gravitational potential energy from the top of the hill to the flat field is

$$\Delta U = -mgh,$$

where m is the mass of the boy and sled together and

$$h = d_1 \sin \theta.$$

The force of friction is different on the slope and on the flat field because the normal force is different. From Figure 6.18b, the force of friction on the slope is

$$f_{k1} = \mu_k N_1 = \mu_k mg \cos \theta.$$

From Figure 6.18c, the force of friction on the flat field is

$$f_{\mathrm{k}2} = \mu_{\mathrm{k}} N_2 = \mu_{\mathrm{k}} mg.$$

The energy dissipated by friction, W_{f}, is equal to the energy dissipated by friction while sliding on the slope, W_1, plus the energy dissipated while sliding on the flat field, W_2:

$$W_{\mathrm{f}} = W_1 + W_2.$$

The energy dissipated by friction on the slope is

$$W_1 = -f_{\mathrm{k}1} d_1,$$

and the energy dissipated by friction on the flat field is

$$W_2 = -f_{\mathrm{k}2} d_2.$$

SIMPLIFY

According to the preceding three equations, the total energy dissipated by friction is given by

$$W_f = -f_{k1} d_1 - f_{k2} d_2.$$

Substituting the two expressions for the friction forces into this equation gives us

$$W_f = -(\mu_{\mathrm{k}} mg \cos\theta) d_1 - (\mu_{\mathrm{k}} mg) d_2.$$

The change in potential energy is obtained by combining the equation $\Delta U = -mgh$ with the expression obtained for the height, $h = d_1 \sin\theta$:

$$\Delta U = -mgd_1 \sin\theta.$$

Since the sled is at rest at the top of the hill and at the end of the ride as well, we have $\Delta K = 0$, and so according to equation 6.29, in this case, $\Delta U = W_{\mathrm{f}}$. Now we can equate the change in potential energy with the energy dissipated by friction:

$$mgd_1 \sin\theta = (\mu_{\mathrm{k}} mg \cos\theta) d_1 + (\mu_{\mathrm{k}} mg) d_2.$$

Canceling out mg on both sides and solving for the distance the boy and sled travel on the flat field, we get

$$d_2 = \frac{d_1(\sin\theta - \mu_\text{k}\cos\theta)}{\mu_\text{k}}.$$

CALCULATE

Putting in the given numerical values, we get

$$d_2 = \frac{(25.0\text{ m})(\sin 35.0^\circ - 0.100\cdot\cos 35.0^\circ)}{0.100} = 122.9153\text{ m}$$

ROUND

All of the numerical values were specified to three significant figures, so we report our answer as

$$d_2 = 123.\text{ m}.$$

DOUBLE-CHECK

The distance that the sled moves on the flat field is a little longer than a football field, which certainly seems possible after coming off a steep hill of length 25 m.

We can double-check our answer by assuming that the friction force between the sled and the snow is the same on the slope of the hill as it is on the flat field,

$$f_\text{k}\mu_\text{k}mg.$$

The change in potential energy would then equal the approximate energy dissipated by friction for the entire distance the sled moves:

$$mgd_1\sin\theta = \mu_\text{k}mg(d_1 + d_2).$$

The approximate distance traveled on the flat field would then be

$$d_2 = \frac{d_1(\sin\theta - \mu_\text{k})}{\mu_\text{k}} = \frac{(25.0\text{ m})(\sin 35.0^\circ - 0.100)}{0.100} = 118$$

This result is close to but less than our answer of 123 m, which we expect because the friction force on the flat field is higher than the friction force on the slope. Thus, our answer seems reasonable.

6.8 Potential Energy and Stability

Let's return to the relationship between force and potential energy. Perhaps it may help you gain physical insight into this relationship if you visualize the potential energy curve as the track of a roller coaster. This analogy is not a perfect one, because a roller coaster moves in a two-dimensional plane or even in three-dimensional space, not in one dimension, and there is some small amount of friction between the cars and the track. Still, it is a good approximation to assume that there is conservation of mechanical energy. The motion of the roller-coaster car can then be described by a potential energy function.

Shown in Figure 6.19 are plots of the potential energy (yellow line following the outline of the track), the total energy (horizontal orange line), and the kinetic energy (difference between these two, the red line) as a function of position for a segment of a roller-coaster ride. You can see that the kinetic energy has a minimum at the highest point of the track, where the speed of the cars is smallest, and the speed increases as the cars roll down the incline. All of these effects are a consequence of the conservation of total mechanical energy.

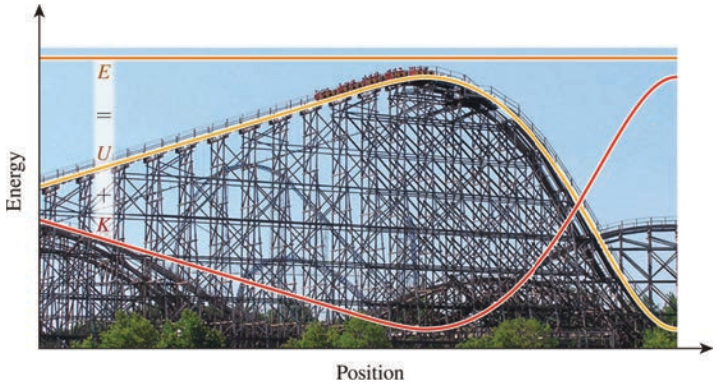

FIGURE 6.19 Total, potential, and kinetic energy for a roller coaster. The yellow line shows the potential energy and follows the roller-coaster track. The red curve shows the kinetic energy, and the orange line at the top is the (constant!) sum of the two.

W. Bauer and G. D. Westfall

Figure 6.20 shows graphs of a potential energy function (part a) and the corresponding force (part b). Because the potential energy can be determined only within an additive constant, the zero value of the potential energy in Figure 6.20a is set at the lowest value. However, for all physical considerations, this is irrelevant. On the other hand, the zero value for the force cannot be chosen arbitrarily.

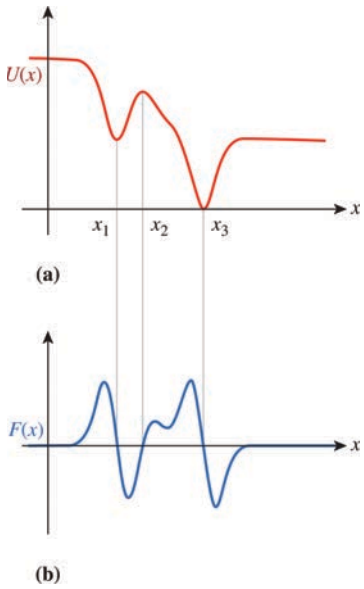

FIGURE 6.20 (a) Potential energy as a function of position; (b) the force corresponding to this potential energy function, as a function of position.

Equilibrium Points

Three special points on the x-coordinate axis of Figure 6.20b are marked by vertical gray lines. These points indicate where the force has a value of zero. Because the force is the derivative of the potential energy with respect to the x-coordinate, the potential energy has an extremum—a maximum or minimum value—at such points. You can clearly see that the potential energies at x_1 and x_3 represent minima, and the potential energy at x_2 is a maximum. At all three points, an object would experience no acceleration, because it is located at an extremum where the force is zero. Because there is no force, Newton's Second Law tells us that there is no acceleration. Thus, these points are equilibrium points.

The equilibrium points in Figure 6.20 represent two different kinds. Points x_1 and x_3 are stable equilibrium points, and x_2 is an unstable equilibrium point. What distinguishes stable and unstable equilibrium points is the response to perturbations (small changes in position around the equilibrium position).

Definition

At **stable equilibrium points**, small perturbations result in small oscillations around the equilibrium point. At **unstable equilibrium points**, small perturbations result in an accelerating movement away from the equilibrium point.

The roller-coaster analogy may be helpful here: If you are sitting in a roller-coaster car at point x_1 or x_3 and someone gives the car a push, it will just rock back and forth on the track, because you are sitting at a local point of lowest energy. However, if the car gets the same small push while sitting at x_2, it will roll down the slope.

What makes an equilibrium point stable or unstable from a mathematical standpoint is the value of the second derivative of the potential energy function, or the curvature. Negative curvature means a local maximum of the potential energy function, and therefore an unstable equilibrium point; a positive curvature indicates a stable equilibrium point. Of course, there is also the situation between a stable and unstable equilibrium, between a positive and negative curvature. This is a point of metastable

equilibrium, with zero local curvature, that is, a value of zero for the second derivative of the potential energy function.

Concept Check 6.10

Which of the four drawings represents a stable equilibrium point for the ball on its supporting surface?

(a)

(b)

(c)

(d)

Turning Points

Figure 6.21a shows the same potential energy function as Figure 6.20, but with the addition of horizontal lines for four different values of the total mechanical energy (E_1 through E_4). For each value of this total energy and for each point on the potential energy curve, we can calculate the value of the kinetic energy by simple subtraction. Let's first consider the largest value of the total mechanical energy shown in the figure, E_1 (blue horizontal line):

$$K_1(x) = E_1 - U(x). \tag{6.30}$$

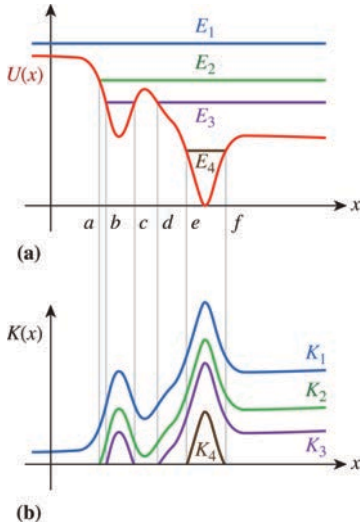

FIGURE 6.21 (a) The same potential energy function as in Figure 6.20. Shown are lines representing four different values of the total energy, E_1 through E_4. (b) The corresponding kinetic energy functions for these four total energies and the potential energy function in the upper part. The gray vertical lines mark the turning points.

The kinetic energy, $K_1(x)$, is shown in Figure 6.21b by the blue curve, which is clearly an upside-down version of the potential energy curve in Figure 6.21a. However, its absolute height is not arbitrary but results from equation 6.30. As previously mentioned, we can always add an arbitrary additive constant to the potential energy, but then we are forced to add the same additive constant to the total mechanical energy, so that their difference, the kinetic energy, remains unchanged.

For the other values of the total mechanical energy in Figure 6.21, an additional complication arises: the condition that the kinetic energy has to be larger than or equal to zero. This condition means that the kinetic energy is not defined in a region where $E_i - U(x)$ is negative. For the total mechanical energy of E_2, the kinetic energy is greater than zero only for $x \geq a$, as indicated in Figure 6.21b by the green curve. Thus, an object moving with total energy E_2 from right to left in Figure 6.21 will reach the point $x = a$ and have zero velocity there. Referring to Figure 6.20, you see that the force at that point is positive, pushing the object to the right, that is, making it turn around. This is why such a point is called a **turning point**. (Turning points are points where the kinetic energy is zero and where a net force moves the object away from the point.) Moving to the right, this object will pick up kinetic energy and follow the same kinetic energy curve from left to right, making its path reversible. This behavior is a consequence of the conservation of total mechanical energy.

An object with total energy equal to E_4 in Figure 6.21 has two turning points in its path: $x = e$ and $x = f$. The object can move only between these two points. It is trapped in this interval and cannot escape. Perhaps the roller-coaster analogy is again helpful: A car released from point $x = e$ will move through the dip in the potential energy curve to the right until it reaches the point $x = f$, where it will reverse direction and move back to $x = e$, never having enough total mechanical energy to escape the dip. The region in which the object is trapped is often referred to as a *potential well*.

Perhaps the most interesting situation is that for which the total energy is E_3. If an object moves in from the right in Figure 6.21 with energy E_3, it will be reflected at the turning point where $x = d$, in complete analogy to the situation at $x = a$ for the object with energy E_2. However, there is another allowed part of the path farther to the left, in the interval $b \leq x \leq c$. If the object starts out in this interval, it remains trapped in a dip, just like the object with energy E_4. Between the allowed intervals $b \leq x \leq c$ and $x \geq d$ is a *forbidden region* that an object with total mechanical energy E_3 cannot cross.

Preview: Atomic Physics

In studying atomic physics, we will again encounter potential energy curves. Particles with energies such as E_4 in Figure 6.21, which are trapped between two turning points, are said to be in *bound states*. One of the most interesting phenomena in atomic and nuclear physics, however, occurs in situations like the one shown in Figure 6.21 for a total mechanical energy of E_3. From our considerations of classical mechanics in this chapter, we expect that an object sitting in a bound state between $b \leq x \leq c$ cannot escape. However, in atomic and nuclear physics applications, a particle in such a bound state has a small probability of escaping out of this potential well and through the classically forbidden region into the region $x \geq d$. This process is called *tunneling*. Depending on the height and width of the barrier, the tunneling probability can be quite large, leading to a fast escape, or quite small, leading to a very slow escape. For example, the isotope ^{235}U of the element uranium, used in nuclear fission power plants and naturally occurring on Earth, has a half-life of over 700 million years, which is the average time that elapses until an alpha particle (a tightly bound cluster of two neutrons and two protons in the nucleus) tunnels through its potential barrier, causing the uranium nucleus to decay. In contrast, the isotope ^{238}U has a half-life of 4500 million years. Thus, much of the original ^{235}U present on Earth has decayed away. The fact that ^{235}U comprises only 0.7% of all naturally occurring uranium means that the first sign that a nation is attempting to use nuclear power, for any purpose, is the acquisition of equipment that can separate ^{235}U from the much more abundant (99.3%) ^{238}U, which is not suitable for nuclear fission power production.

The previous paragraph is included to whet your appetite for things to come. In order to understand the processes of atomic and nuclear physics, you'll need to be familiar with quite a few more concepts. However, the basic considerations of energy introduced here will remain virtually unchanged.

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- Potential energy, *U,* is the energy stored in the configuration of a system of objects that exert forces on one another.
- Gravitational potential energy is defined as $U_g = mgy$.
- The potential energy associated with elongating a spring from its equilibrium position at $x = 0$ is $U_s(x) = \frac{1}{2} kx^2$.
- A conservative force is a force for which the work done over any closed path is zero. A force that does not fulfill this requirement is a nonconservative force.
- For any conservative force, the change in potential energy due to some spatial rearrangement of a system is equal to the negative of the work done by the conservative force during this spatial rearrangement.
- The relationship between a potential energy and the corresponding conservative force is

$$\Delta U = U(x) - U(x_0) = -\int_{x_0}^{x} F_x(x\prime)dx\prime.$$

- In one-dimensional situations, the force component can be obtained from the potential energy using $F_x(x) = -\dfrac{dU(x)}{dx}$.
- The mechanical energy, *E,* is the sum of the kinetic energy and the potential energy: $E = K + U$.
- The total mechanical energy is conserved for any mechanical process inside an isolated system that involves only conservative forces: $\Delta E = \Delta K + \Delta U = 0$. An alternative way of expressing this law of conservation of mechanical energy is $K + U = K_0 + U_0$.
- The total energy—the sum of all forms of energy, mechanical or other—is always conserved in an isolated system. This holds for conservative as well as nonconservative forces: $E_{\text{total}} = E_{\text{mechanical}} + E_{\text{other}} = K + U + E_{\text{other}} = \text{constant}$.

- Energy problems involving nonconservative forces can be solved using the work-energy theorem: $W_{\mathrm{f}} = \Delta K + \Delta U$.
- At stable equilibrium points, small perturbations result in small oscillations around the equilibrium point; at unstable equilibrium points, small perturbations result in an accelerating movement away from the equilibrium point.
- Turning points are points where the kinetic energy is zero and where a net force moves the object away from the point.

ANSWERS TO SELF-TEST OPPORTUNITIES

6.1 The potential energy is proportional to the inverse of the distance between the two objects. Examples of these forces are the force of gravity (see Chapter 12) and the electrostatic force (see Chapter 21).

6.2 To handle this problem with air resistance included, we would have introduced the work done by air resistance, which can be treated as a friction force. We would have modified our statement of energy conservation to reflect the fact that work, W_f, is done by the friction force:

$$W_f + K + U = K_0 + U_0.$$

The solution would have to be done numerically because the work done by friction in this case would depend on the distance that the rock actually traveled through the air.

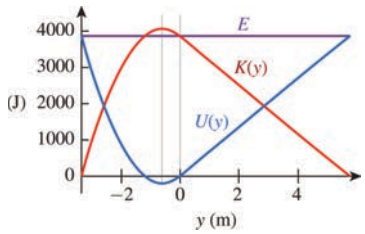
6.3 The lighter-colored ball descends to a lower elevation earlier in its motion and thus converts more of its potential energy to kinetic energy early on. Greater kinetic energy means higher speed. Thus, the lighter-colored ball reaches higher speeds earlier and is able to move to the bottom of the track faster, even though its path length is greater.

6.4 The speed is at a maximum where the kinetic energy is at a maximum:

$$K(y) = U(-3.3\ \text{m}) - U(y) = (3856\ \text{J}) - (671\ \text{J/m})y - 557.5$$

$$\frac{d}{dy}K(y) = -(671\ \text{J/m}) - \left(1115\ \text{J/m}^2\right)y = 0 \Rightarrow y = -0.602$$

$$v(-0.602\ \text{m}) = \sqrt{2K(-0.602\ \text{m})/\text{m}} = 10.89\ \text{m/s}.$$



Note that the value at which the speed is maximum is the equilibrium position of the spring once it is loaded with the human cannonball.

6.5 The net force at the maximum stretching is $F = k(L_{\text{max}} - L_{\text{jumper}} - L_0) - mg$. Therefore, the acceleration at this point is $a = k(L_{\text{max}} - L_{\text{jumper}} - L_0)/m - g$. Inserting the expression we found for L_0 gives

$$a = \sqrt{\frac{2gL_{\text{max}}k}{m}} - g.$$

The maximum acceleration increases with the square root of the spring constant. If one wants to jump from a great height, L_{max}, a very soft bungee cord is needed.

PROBLEM-SOLVING GUIDELINES: CONSERVATION OF ENERGY

1. Many of the problem-solving guidelines given in Chapter 5 apply to problems involving conservation of energy as well. It is important to identify the system and determine the state of the objects in it at different key times, such as the beginning and end of each kind of motion. You should also identify which forces in the situation are conservative or nonconservative, because they affect the system in different ways.

2. Try to keep track of each kind of energy throughout the problem situation. When does the object have kinetic energy? Does gravitational potential energy increase or decrease? Where is the equilibrium point for a spring?

3. Remember that you can choose where potential energy is zero, so try to determine what choice will simplify the calculations.

4. A sketch is almost always helpful, and often a free-body diagram is useful as well. In some cases, drawing graphs of potential energy, kinetic energy, and total mechanical energy is a good idea.

MULTIPLE-CHOICE QUESTIONS

6.1 A block of mass 5.0 kg slides without friction at a speed of 8.0 m/s on a horizontal table surface until it strikes and sticks to a horizontal spring (with spring constant of k = 2000. N/m and very small mass), which in turn is attached to a wall. How far is the spring compressed before the mass comes to rest?

a) 0.40 m

b) 0.54 m

c) 0.30 m

d) 0.020 m

e) 0.67 m

6.2 A pendulum swings in a vertical plane. At the bottom of the swing, the kinetic energy is 8 J and the gravitational potential energy is 4 J. At the highest position of the swing, the kinetic and gravitational potential energies are

a) kinetic energy = 0 J and gravitational potential energy = 4 J.

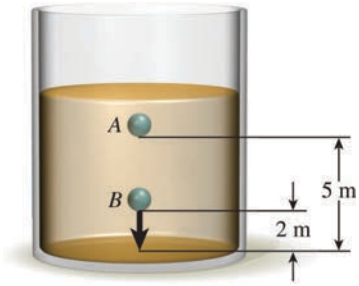
b) kinetic energy = 12 J and gravitational potential energy = 0 J.

c) kinetic energy = 0 J and gravitational potential energy = 12 J.

d) kinetic energy = 4 J and gravitational potential energy = 8 J.

e) kinetic energy = 8 J and gravitational potential energy = 4 J.

6.3 A ball of mass 0.50 kg is released from rest at point *A*, which is 5.0 m above the bottom of a tank of oil, as shown in the figure. At point *B*, which is 2.0 m above the bottom of the tank, the ball has a speed of 6.0 m/s. The work done on the ball by the force of fluid friction is



a) +15 J.

b) +9 J.

c) -15 J.

d) -9 J.

e) -5.7 J.

6.4 A child throws three identical marbles from the same height above the ground so that they land on the *flat* roof of a building. The marbles are launched with the same initial speed. The first marble, marble A, is thrown at an angle of 75° above horizontal, while marbles B and C are thrown with launch angles of 60° and 45°, respectively. Neglecting air resistance, rank the marbles according to the speeds with which they hit the roof.

a) A<B<C

b) C<B<A

c) A and C have the same speed; B has a lower speed.

d) B has the highest speed; A and C have the same speed.

e) A, B, and C all hit the roof with the same speed.

6.5 Which of the following is *not* a valid potential energy function for the spring force $F = -kx$?

a) $\left(\frac{1}{2}\right)kx^2$

b) $\left(\frac{1}{2}\right)kx^2 + 10\ \text{J}$

c) $\left(\frac{1}{2}\right)kx^2 - 10\ \text{J}$

d) $-\left(\frac{1}{2}\right)kx^2$

e) None of these are valid.

6.6 You use your hand to stretch a spring to a displacement *x* from its equilibrium position and then slowly bring it back to that position. Which is true?

a) The spring's ΔU is positive.

b) The spring's ΔU is negative.

c) The hand's ΔU positive.

d) The bhand's ΔU is negative.

e) None of these statements are true.

6.7 In Question 6, what is the work done by the hand?

a) $-\left(\frac{1}{2}\right)kx^2$

b) $+\left(\frac{1}{2}\right)kx^2$

c) $\left(\frac{1}{2}\right)mv^2$, where v is the speed of the hand

d) zero

e) none of these

6.8 Which of the following is *not* a unit of energy?

a) newton-meter

b) joule

c) kilowatt-hour

d) $\text{kg m}^2/\text{s}^2$

e) All of these are units of energy.

6.9 A spring has a spring constant of 80. N/m. How much potential energy does it store when stretched by 1.0 cm?

a) $4.0 \cdot 10^{-3}$ J

b) 0.40 J

c) 80 J

d) 800 J

e) 0.8 J

6.10 What is the maximum acceleration that the human cannonball of Solved Problem 6.4 experiences?

a) 1.00g

b) 2.14g

c) 3.25g

d) 4.48g

e) 7.30g

6.11 For an object sliding on the ground, the friction force

a) always acts in the same direction as the displacement.

b) always acts in a direction perpendicular to the displacement.

c) always acts in a direction opposite to the displacement.

d) acts either in the same direction as the displacement or in the direction opposite to the displacement depending on the value of the coefficient of kinetic friction.

6.12 Some forces in nature vary with the inverse of the distance squared between two objects. For a force like this, how does the potential energy vary with the distance between the two objects?

a) The potential energy varies with the distance.

b) The potential energy varies with the distance squared.

c) The potential energy varies with the inverse of the distance.

d) The potential energy varies with the inverse of the distance squared.

e) The potential energy does not depend on the distance.

6.13 A baseball is dropped from the top of a building. Air resistance acts on the baseball as it drops. Which of the following statements is true?

a) The change in potential energy of the baseball as it falls is equal to the kinetic energy of the baseball just before it strikes the ground.

b) The change in potential energy of the baseball as it falls is greater than the kinetic energy of the baseball just before it strikes the

ground.

c) The change in potential energy of the baseball as it falls is less than the kinetic energy of the baseball just before it strikes the ground.

d) The change in potential energy of the baseball is equal to the energy lost due to the friction from the air resistance while the ball is falling.

CONCEPTUAL QUESTIONS

6.14 Can the kinetic energy of an object be negative? Can the potential energy of an object be negative?

6.15 a) If you jump off a table onto the floor, is your mechanical energy conserved? If not, where does it go? b) A car moving down the road smashes into a tree. Is the mechanical energy of the car conserved? If not, where does it go?

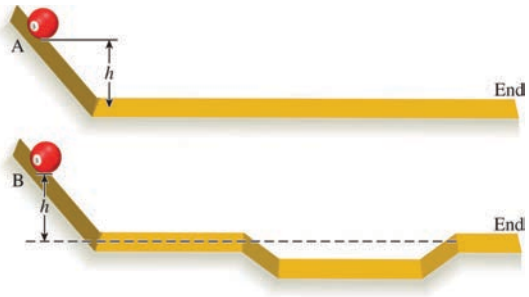
6.16 How much work do you do when you hold a bag of groceries while standing still? How much work do you do when carrying the same bag a distance *d* across the parking lot of the grocery store?

6.17 An arrow is placed on a bow, the bowstring is pulled back, and the arrow is shot straight up into the air; the arrow then comes back down and sticks into the ground. Describe all of the changes in work and energy that occur.

6.18 Two identical billiard balls start at the same height and the same time and roll along different tracks, as shown in the figure.

a) Which ball has the highest speed at the end?

b) Which one will get to the end first?



6.19 A girl of mass 49.0 kg is on a swing, which has a mass of 1.0 kg. Suppose you pull her back until her center of mass is 2.0 m above the ground. Then you let her go, and she swings out and returns to the same point. Are all forces acting on the girl and swing conservative?

6.20 Can a potential energy function be defined for the force of friction?

6.21 Can the potential energy of a spring be negative?

6.22 One end of a rubber band is tied down, and you pull on the other end to trace a complicated *closed* trajectory. If you measured the elastic force F at every point, took its scalar product with the local displacements, $F \bullet \Delta\vec{r}$, and then summed all of these, what would you get?

6.23 Can a unique potential energy function be identified with a particular conservative force?

6.24 In skydiving, the vertical velocity component of the skydiver is typically zero at the moment he or she leaves the plane; the vertical component of the velocity then increases until the skydiver reaches terminal speed (see Chapter 4). For a simplified model of this motion, we assume that the horizontal velocity component is zero and that the vertical velocity component increases linearly, with acceleration $a_y = -g$ until the skydiver reaches terminal velocity, after which it stays constant. Thus, our simplified model assumes free fall without air resistance followed by falling at constant speed. Sketch the kinetic energy, potential energy, and total energy as a function of time for this model.

6.25 A projectile of mass m is launched from the ground at $t = 0$ with a speed v_0 and at an angle θ_0 above the horizontal. Assuming that air resistance is negligible, write the kinetic, potential, and total energies of the projectile as explicit functions of time.

6.26 The energy height, *H,* of an aircraft of mass m at altitude h and with speed v is defined as its total energy (with the zero of the potential energy taken at ground level) divided by its weight. Thus, the energy height is a quantity with units of length.

a) Derive an expression for the energy height, *H,* in terms of the quantities *m, h,* and *v*.

b) A Boeing 747 jet with mass $3.5 \cdot 10^5$ kg is cruising in level flight at 250.0 m/s at an altitude of 10.0 km. Calculate the value of its energy height.

Note: The energy height is the maximum altitude an aircraft can reach by "zooming" (pulling into a vertical climb without changing the engine thrust). This maneuver is not recommended for a 747, however.

6.27 A body of mass *m* moves in one dimension under the influence of a force, *F*(*x*), which depends only on the body's position.

a) Prove that Newton's Second Law and the law of conservation of energy for this body are exactly equivalent.

b) Explain, then, why the law of conservation of energy is considered to be of greater significance than Newton's Second Law.

6.28 The molecular bonding in a diatomic molecule such as the nitrogen (N_2) molecule can be modeled by the Lennard-Jones potential, which has the form

$$U(x) = 4U_0 \left(\left(\frac{x_0}{x} \right)^{12} - \left(\frac{x_0}{x} \right)^{6} \right),$$

where *x* is the separation distance between the two nuclei and x_0 and U_0 are constants. Determine, in terms of these constants, the following:

a) the corresponding force function;

b) the equilibrium separation x_E, which is the value of *x* for which the two atoms experience zero force from each other; and

c) the nature of the interaction (repulsive or attractive) for separations larger and smaller than x_E.

6.29 A particle of mass *m* moving in the *xy*-plane is confined by a two-dimensional potential function, $U(x, y) = \frac{1}{2}k\left(x^2 + y^2\right)$.

a) Derive an expression for the net force, $\overrightarrow{F} = F_x\hat{x} + F_y\hat{y}$.

b) Find the equilibrium point on the *xy*-plane.

c) Describe qualitatively the effect of the net force.

d) What is the magnitude of the net force on the particle at the coordinate (3.00, 4.00) in centimeters if *k* = 10.0 N/cm?

e) What are the turning points if the particle has 10.0 J of total mechanical energy?

6.30 For a rock dropped from rest from a height *h,* to calculate the speed just before it hits the ground, we use the conservation of

mechanical energy and write $mgh = \frac{1}{2}mv^2$. The mass cancels out, and we solve for v. A very common error made by some beginning physics students is to assume, based on the appearance of this equation, that they should set the kinetic energy equal to the potential energy at the same point in space. For example, to calculate the speed v_1 of the rock at some height $y_1 < h$, they often write $mgy_1 = \frac{1}{2}mv_1^2$ and solve for v_1. Explain why this approach is wrong.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 6.1

6.31 What is the gravitational potential energy of a 2.00-kg book 1.50 m above the floor?

6.32

a) If the gravitational potential energy of a 40.0-kg rock is 500. J relative to a value of zero on the ground, how high is the rock above the ground?

b) If the rock were lifted to twice its original height, how would the value of its gravitational potential energy change?

6.33 A rock of mass 0.773 kg is hanging from a string of length 2.45 m on the Moon, where the gravitational acceleration is a sixth of that on Earth. What is the change in gravitational potential energy of this rock when it is moved so that the angle of the string changes from 3.31° to 14.01°? (Both angles are measured relative to the vertical.)

6.34 A 20.0-kg child is on a swing attached to ropes that are L = 1.50 m long. Take the zero of the gravitational potential energy to be at the position of the child when the ropes are horizontal.

a) Determine the child's gravitational potential energy when the child is at the lowest point of the circular trajectory.

b) Determine the child's gravitational potential energy when the ropes make an angle of 45.0° relative to the vertical.

c) Based on these results, which position has the higher potential energy?

Section 6.3

6.35 A $1.50 \cdot 10^3$-kg car travels 2.50 km up an incline at constant velocity. The incline has an angle of 3.00° with respect to the horizontal. What is the change in the car's potential energy? What is the net work done on the car?

6.36 A constant force of 40.0 N is needed to keep a car traveling at constant speed as it moves 5.00 km along a road. How much work is done? Is the work done on or by the car?

6.37 A piñata of mass 3.27 kg is attached to a string tied to a hook in the ceiling. The length of the string is 0.810 m, and the piñata is released from rest from an initial position in which the string makes an angle of 56.5° with the vertical. What is the work done by gravity by the time the string is in a vertical position for the first time?

Section 6.4

•6.38 A particle is moving along the x-axis subject to the potential energy function $U(x) = a(1/x) + bx^2 + cx - d$, where a = 7.00 J m, b = 10.0 J/m^2, c = 6.00 J/m, and d = 28.0 J.

a) Express the force felt by the particle as a function of x.

b) Plot this force and the potential energy function.

c) Determine the net force on the particle at the coordinate x = 2.00 m.

•6.39 Calculate the force $F(y)$ associated with each of the following potential energies:

a) $U(y) = ay^3 - by^2$

b) $U(y) = U_0 \sin(cy)$

•6.40 The potential energy of a certain particle is given by $U(x, z) = ax^2 + bz^3$, where a and b are constants. Find the force vector exerted on the particle.

Section 6.5

6.41 A ball is thrown up in the air, reaching a height of 5.00 m. Using energy conservation considerations, determine its initial speed.

6.42 A cannonball of mass 5.99 kg is shot from a cannon at an angle of 50.21° relative to the horizontal and with an initial speed of 52.61 m/s. As the cannonball reaches the highest point of its trajectory, what is the gain in its potential energy relative to the point from which it was shot?

6.43 A basketball of mass 0.624 kg is shot from a vertical height of 1.20 m and at a speed of 20.0 m/s. After reaching its maximum height, the ball moves into the hoop on its downward path, at 3.05 m above the ground. Using the principle of energy conservation, determine how fast the ball is moving just before it enters the hoop.

•**6.44** A classmate throws a 1.00-kg book from a height of 1.00 m above the ground straight up into the air. The book reaches a maximum height of 3.00 m above the ground and begins to fall back. Assume that 1.00 m above the ground is the reference level for zero gravitational potential energy. Determine

a) the gravitational potential energy of the book when it hits the ground.

b) the velocity of the book just before hitting the ground.

•**6.45** Suppose you throw a 0.0520-kg ball with a speed of 10.0 m/s and at an angle of 30.0° above the horizontal from a building 12.0 m high.

a) What will be its kinetic energy when it hits the ground?

b) What will be its speed when it hits the ground?

•**6.46** A uniform chain of total mass m is laid out straight on a frictionless table and held stationary so that one-third of its length, L = 1.00 m, is hanging vertically over the edge of the table. The chain is then released. Determine the speed of the chain at the instant when only one-third of its length remains on the table.

•**6.47** a) If you are at the top of a toboggan run that is 40.0 m high, how fast will you be going at the bottom, provided you can ignore friction between the sled and the track?

b) Does the steepness of the run affect how fast you will be going at the bottom?

c) If you do not ignore the small friction force, does the steepness of the track affect the value of the speed at the bottom?

Section 6.6

6.48 A block of mass 0.773 kg on a spring with spring constant 239.5 N/m oscillates vertically with amplitude 0.551 m. What is the speed of this block at a distance of 0.331 m from the equilibrium position?

6.49 A spring with k = 10.0 N/cm is initially stretched 1.00 cm from its equilibrium length.

a) How much more energy is needed to further stretch the spring to 5.00 cm beyond its equilibrium length?

b) From this new position, how much energy is needed to compress the spring to 5.00 cm shorter than its equilibrium position?

•**6.50** A 5.00-kg ball of clay is thrown downward from a height of 3.00 m with a speed of 5.00 m/s onto a spring with k = 1600. N/m. The clay compresses the spring a certain maximum amount before momentarily stopping.

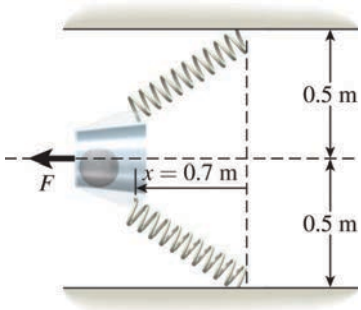
a) Find the maximum compression of the spring.

b) Find the total work done on the clay during the spring's compression.

•**6.51** A slingshot that launches a stone horizontally consists of two light, identical springs (with spring constants of 30.0 N/m) and a light cup that holds a 1.00-kg stone. Each spring has an equilibrium length of 50.0 cm. When the springs are in equilibrium, they line up vertically. Suppose that the cup containing the mass is pulled to x = 70.0 cm to the left of the vertical and then released. Determine

a) the system's total mechanical energy; and

b) the speed of the stone at x = 0.



•**6.52** Suppose the stone in Problem 6.51 is instead launched vertically and the mass is a lot smaller (m = 0.100 kg). Take the zero

of the gravitational potential energy to be at the equilibrium point.

a) Determine the total mechanical energy of the system.

b) How fast is the stone moving as it passes the equilibrium point?

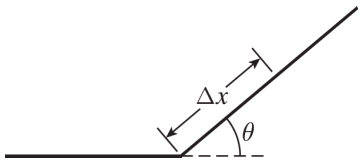
Section 6.7

6.53 A 80.0-kg fireman slides down a 3.00-m pole by applying a frictional force of 400. N against the pole with his hands. If he slides from rest, how fast is he moving once he reaches the ground?

6.54 A large air-filled 0.100-kg plastic ball is thrown up into the air with an initial speed of 10.0 m/s. At a height of 3.00 m, the ball's speed is 3.00 m/s. What fraction of its original energy has been lost to air friction?

6.55 How much mechanical energy is lost to friction if a 55.0-kg skier slides down a ski slope at constant speed of 14.4 m/s? The slope is 123.5 m long and makes an angle of 14.7° with respect to the horizontal.

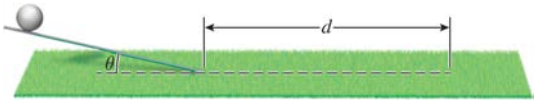
•**6.56** A truck of mass 10,212 kg moving at a speed of 61.2 mph has lost its brakes. Fortunately, the driver finds a runaway lane, a gravel-covered incline that uses friction to stop a truck in such a situation; see the figure. In this case, the incline makes an angle of $\theta = 40.15°$ with the horizontal, and the gravel has a coefficient of friction of 0.634 with the tires of the truck. How far along the incline (Δx) does the truck travel before it stops?



•**6.57** A snowboarder of mass 70.1 kg (including gear and clothing), starting with a speed of 5.10 m/s, slides down a slope at an angle $\theta = 37.1°$ with the horizontal. The coefficient of kinetic friction is 0.116. What is the net work done on the snowboarder in the first 5.72 s of descent?

•**6.58** The greenskeepers of golf courses use a stimpmeter to determine how "fast" their greens are. A stimpmeter is a straight aluminum bar with a V-shaped groove on which a golf ball can roll. It is designed to release the golf ball once the angle of the bar with the ground reaches a value of $\theta = 20.0°$. The golf ball (mass = 1.62 oz = 0.0459 kg) rolls 30.0 in down the bar and then continues to roll along the green for several feet. This distance is called the "reading." The test is done on a level part of the green, and stimpmeter readings

between 7 and 12 ft are considered acceptable. For a stimpmeter reading of 11.1 ft, what is the coefficient of friction between the ball and the green? (The ball is rolling and not sliding, as we usually assume when considering friction, but this does not change the result in this case.)



•6.59 A 1.00-kg block is pushed up and down a rough plank of length L = 2.00 m, inclined at 30.0° above the horizontal. From the bottom, it is pushed a distance $L/2$ up the plank, then pushed back down a distance $L/4$, and finally pushed back up the plank until it reaches the top end. If the coefficient of kinetic friction between the block and plank is 0.300, determine the work done by the block against friction.

••6.60 A 1.00-kg block initially at rest at the top of a 4.00-m incline with a slope of 45.0° begins to slide down the incline. The upper half of the incline is frictionless, while the lower half is rough, with a coefficient of kinetic friction $\mu_k = 0.300$.

a) How fast is the block moving midway along the incline, before entering the rough section?

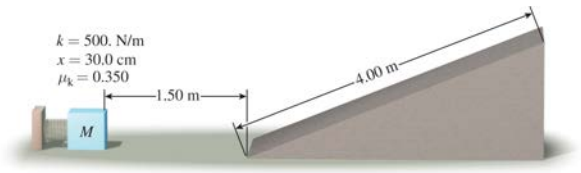
b) How fast is the block moving at the bottom of the incline?

••6.61 A spring with a spring constant of 500. N/m is used to propel a 0.500-kg mass up an inclined plane. The spring is compressed 30.0 cm from its equilibrium position and launches the mass from rest across a horizontal surface and onto the plane. The plane has a length of 4.00 m and is inclined at 30.0°. Both the plane and the horizontal surface have a coefficient of kinetic friction with the mass of 0.350. When the spring is compressed, the mass is 1.50 m from the bottom of the plane.

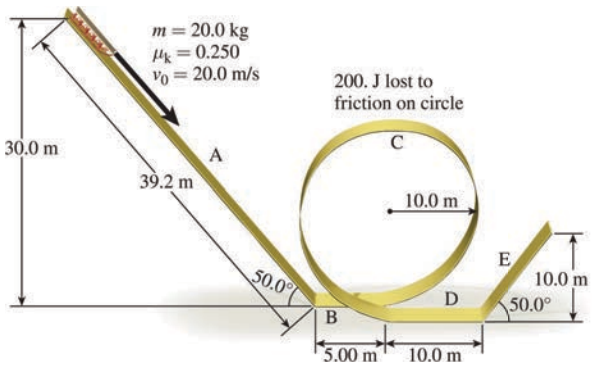
a) What is the speed of the mass as it reaches the bottom of the plane?

b) What is the speed of the mass as it reaches the top of the plane?

c) What is the total work done by friction from the beginning to the end of the mass's motion?

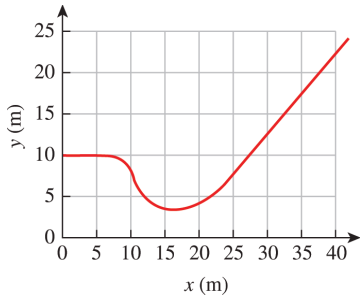


••6.62 The sled shown in the figure leaves the starting point with a velocity of 20.0 m/s. Use the work-energy theorem to calculate the sled's speed at the end of the track or the maximum height it reaches if it stops before reaching the end.



Section 6.8

•6.63 On the segment of roller-coaster track shown in the figure, a cart of mass 237.5 kg starts at x = 0 with a speed of 16.5 m/s. Assuming that the dissipation of energy due to friction is small enough to be ignored, where is the turning point of this trajectory?



•6.64 A 70.0-kg skier moving horizontally at 4.50 m/s encounters a 20.0° incline.

a) How far up the incline will the skier move before she momentarily stops, ignoring friction?

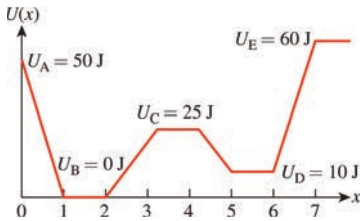
b) How far up the incline will the skier move if the coefficient of kinetic friction between the skies and snow is 0.100?

•6.65 A 0.200-kg particle is moving along the x-axis, subject to the potential energy function shown in the figure, where $U_A = 50.0$ J, $U_B = 0$ J, $U_C = 25.0$ J, $U_D = 10.0$ J, and $U_E = 60.0$ J along the path. If the particle was initially at x = 4.00 m and had a total mechanical energy of 40.0 J, determine:

a) the particle's speed at x = 3.00 m,

b) the particle's speed at x = 4.50 m, and

c) the particle's turning points.



Additional Exercises

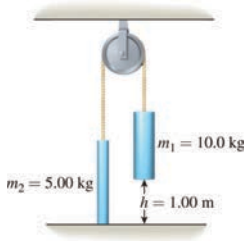
6.66 A ball of mass 1.84 kg is dropped from a height $y_1 = 1.49$ m and then bounces back up to a height of $y_2 = 0.87$ m. How much mechanical energy is lost in the bounce? The effect of air resistance has been experimentally found to be negligible in this case, and you can ignore it.

6.67 A car of mass 987 kg is traveling on a horizontal segment of a freeway with a speed of 64.5 mph. Suddenly, the driver has to hit the brakes hard to try to avoid an accident up ahead. The car does not have an ABS (antilock braking system), and the wheels lock, causing the car to slide some distance before it is brought to a stop by the friction force between its tires and the road surface. The coefficient of kinetic friction is 0.301. How much mechanical energy is lost to heat in this process?

6.68 Two masses are connected by a light string that goes over a light, frictionless pulley, as shown in the figure. The 10.0-kg mass is released and falls through a vertical distance of 1.00 m before hitting the ground. Use conservation of mechanical energy to determine:

a) how fast the 5.00-kg mass is moving just before the 10.0-kg mass hits the ground; and

b) the maximum height attained by the 5.00-kg mass.



6.69 In 1896 in Waco, Texas, William George Crush, owner of the K-T (or "Katy") Railroad, parked two locomotives at opposite ends of a 6.4-km-long track, fired them up, tied their throttles open, and then allowed them to crash head-on at full speed in front of 30,000 spectators. Hundreds of people were hurt by flying debris; a few were killed. Assuming that each locomotive weighed $1.2 \cdot 10^6$ N and its acceleration along the track was a constant 0.26 m/s^2, what was the total kinetic energy of the two locomotives just before the collision?

Published 1896 The Texas Collection, Baylor University, Waco, Texas

6.70 A baseball pitcher can throw a 5.00-oz baseball with a speed measured by a radar gun to be 90.0 mph. Assuming that the force exerted by the pitcher on the ball acts over a distance of two arm lengths, each 28.0 in, what is the average force exerted by the pitcher on the ball?

6.71 A 1.50-kg ball has a speed of 20.0 m/s when it is 15.0 m above the ground. What is the total energy of the ball?

6.72 If it takes an average force of 5.50 N to push a 4.50-g dart 6.00 cm into a dart gun, assuming that the barrel is frictionless, how fast will the dart exit the gun?

6.73 A high jumper approaches the bar at 9.00 m/s. What is the highest altitude the jumper can reach, if he does not use any additional push off the ground and is moving at 7.00 m/s as he goes over the bar and if he stays upright during the jump?

6.74 A roller coaster is moving at 2.00 m/s at the top of the first hill (h = 40.0 m). Ignoring friction and air resistance, how fast will the roller coaster be moving at the top of a subsequent hill, which is 15.0 m high?

6.75 You are on a swing with a chain 4.00 m long. If your maximum displacement from the vertical is 35.0°, how fast will you be moving at the bottom of the arc?

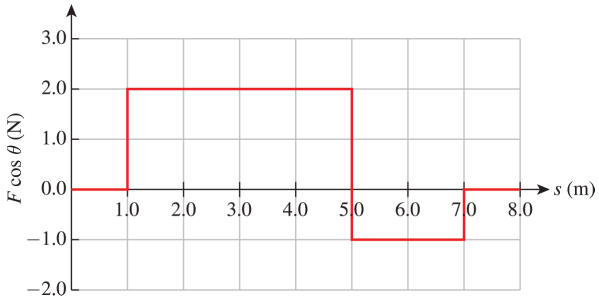
6.76 A truck is descending a winding mountain road. When the truck is 680. m above sea level and traveling at 15.0 m/s, its brakes fail. What is the maximum possible speed of the truck at the foot of the mountain, 550. m above sea level?

6.77 Tarzan swings on a taut vine from his tree house to a limb on a neighboring tree, which is located a horizontal distance of 10.0 m from and a vertical distance of 4.00 m below his starting point. Amazingly, the vine neither stretches nor breaks; Tarzan's trajectory is thus a portion of a circle. If Tarzan starts with zero speed, what is his speed when he reaches the limb?

6.78 The graph shows the component ($F \cos \theta$) of the net force that acts on a 2.00-kg block as it moves along a flat horizontal surface. Find

a) the net work done on the block;

b) the final speed of the block if it starts from rest at $s = 0$.



•**6.79** A 3.00-kg model rocket is launched vertically upward with sufficient initial speed to reach a height of $1.00 \bullet 10^2$m, even though air resistance (a nonconservative force) performs $-8.00 \cdot 10^2$ J of work on the rocket. How high would the rocket have gone, if there were no air resistance?

•**6.80** A 0.500-kg mass is attached to a horizontal spring with k = 100. N/m. The mass slides across a frictionless surface. The spring is stretched 25.0 cm from equilibrium, and then the mass is released from rest.

a) Find the mechanical energy of the system.

b) Find the speed of the mass when it has moved 5.00 cm.

c) Find the maximum speed of the mass.

•**6.81** You have decided to move a refrigerator (mass = 81.3 kg, including all the contents) to the other side of a room. You slide it across the floor on a straight path of length 6.35 m, and the coefficient of kinetic friction between floor and fridge is 0.437. Happy about your accomplishment, you leave the apartment. Your

roommate comes home, wonders why the fridge is on the other side of the room, picks it up (you have a strong roommate!), carries it back to where it was originally, and puts it down. How much net mechanical work have the two of you done together?

•**6.82** A 1.00-kg block compresses a spring for which k = 100. N/m by 20.0 cm; the spring is then released, and the block moves across a horizontal, frictionless table, where it hits and compresses another spring, for which k = 50.0 N/m. Determine

a) the total mechanical energy of the system;

b) the speed of the mass while moving freely between springs; and

c) the maximum compression of the second spring.

•**6.83** A 1.00-kg block is resting against a light, compressed spring at the bottom of a rough plane inclined at an angle of 30.0°; the coefficient of kinetic friction between block and plane is $\mu_k = 0.100$. Suppose the spring is compressed 10.0 cm from its equilibrium length. The spring is then released, and the block separates from the spring and slides up the incline a distance of only 2.00 cm beyond the spring's normal length before stopping. Determine

a) the change in total mechanical energy of the system; and

b) the spring constant k.

•**6.84** A 0.100-kg ball is dropped from a height of 1.00 m and lands on a light (approximately massless) cup mounted on top of a light, vertical spring initially at its equilibrium position. The maximum compression of the spring is to be 10.0 cm.

a) What is the required spring constant of the spring?

b) Suppose you ignore the change in the gravitational energy of the ball during the 10.0-cm compression. What is the percentage difference between the calculated spring constant for this case and the answer obtained in part (a)?

•**6.85** A mass of 1.00 kg attached to a spring with a spring constant of 100. N/m oscillates horizontally on a smooth frictionless table

with an amplitude of 0.500 m. When the mass is 0.250 m away from equilibrium, determine:

a) its total mechanical energy;

b) the system's potential energy and the mass's kinetic energy; and

c) the mass's kinetic energy when it is at the equilibrium point.

d) Suppose there was friction between the mass and the table so that the amplitude was cut in half after some time. By what factor has the mass's maximum kinetic energy changed?

e) By what factor has the maximum potential energy changed?

•**6.86** Bolo, the human cannonball, is ejected from a 3.50-m long barrel. If Bolo (m = 80.0 kg) has a speed of 12.0 m/s at the top of his trajectory, 15.0 m above the ground, what was the average force exerted on him while in the barrel?

•**6.87** A 1.00-kg mass is suspended vertically from a spring with k = 100. N/m and oscillates with an amplitude of 0.200 m. At the top of its oscillation, the mass is hit in such a way that it instantaneously moves down with a speed of 1.00 m/s. Determine

a) its total mechanical energy;

b) how fast it is moving as it crosses the equilibrium point; and

c) its new amplitude.

•**6.88** A runner reaches the top of a hill with a speed of 6.50 m/s. He descends 50.0 m and then ascends 28.0 m to the top of the next hill. His speed is now 4.50 m/s. The runner has a mass of 83.0 kg. The total distance that the runner covers is 400. m, and there is a constant resistance to motion of 9.00 N. Use energy considerations to find the work done by the runner over the total distance.

•**6.89** A package is dropped on a horizontal conveyor belt. The mass of the package is m, the speed of the conveyor belt is v, and the coefficient of kinetic friction between the package and the belt is μ_k.

a) How long does it take for the package to stop sliding on the belt?

b) What is the package's displacement during this time?

c) What is the energy dissipated by friction?

d) What is the total work done by the conveyor belt?

•**6.90** A father exerts a $2.40 \cdot 10^2$ N force to pull a sled with his daughter on it (combined mass of 85.0 kg) across a horizontal surface. The rope with which he pulls the sled makes an angle of 20.0° with the horizontal. The coefficient of kinetic friction is 0.200, and the sled moves a distance of 8.00 m. Find

a) the work done by the father;

b) the work done by the friction force; and

c) the total work done by all the forces.

•**6.91** A variable force acting on a 0.100-kg particle moving in the *xy*-plane is given by $F(x, y) = \left(x^2\hat{x} + y^2\hat{y}\right)$ N, where x and y are in meters. Suppose that due to this force, the particle moves from the origin, *O*, to point *S*, with coordinates (10.0 m, 10.0 m). The coordinates of points *P* and *Q* are (0 m, 10.0 m) and (10.0 m, 0 m), respectively. Determine the work performed by the force as the particle moves along each of the following paths:

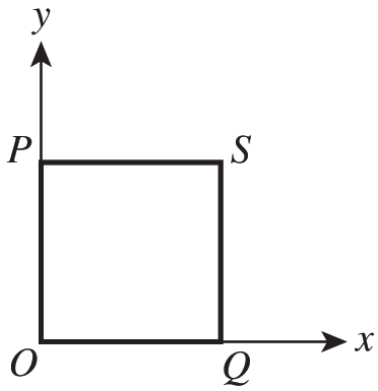
a) *OPS*

b) *OQS*

c) *OS*

d) *OPSQO*

e) *OQSPO*



••**6.92** In the situation in Problem 6.91, suppose there is friction between the 0.100-kg particle and the *xy*-plane, with $\mu_k = 0.100$. Determine the net work done by all forces on this particle when it takes each of the following paths:

a) *OPS*

b) OQS

c) OS

d) $OPSQO$

e) $OQSPO$

MULTI-VERSION EXERCISES

6.93 A snowboarder starts from rest, rides 38.09 m down a snow-covered slope that makes an angle of 30.15° with the horizontal, and reaches the flat snow near the lift. How far will she travel along the flat snow if the coefficient of kinetic friction between her board and the snow is 0.02501?

6.94 A snowboarder starts from rest, rides 30.37 m down a snow-covered slope that makes an angle of 30.35° with the horizontal, and reaches the flat snow near the lift. She travels 506.4 m along the flat snow. What is the coefficient of kinetic friction between her board and the snow?

6.95 A snowboarder starts from rest, rides down a snow-covered slope that makes an angle 30.57° with the horizontal, and reaches the flat snow near the lift. She travels 478.0 m along the flat snow. The coefficient of kinetic friction between her board and the snow is 0.03281. How far did she travel down the slope?

6.96 A batter hits a pop-up straight up in the air from a height of 1.397 m. The baseball rises to a height of 7.653 m above the ground. Ignoring air resistance, what is the speed of the baseball when the catcher gloves it 1.757 m above the ground?

6.97 A batter hits a pop-up straight up in the air from a height of 1.581 m. The baseball rises to a height h above the ground. The speed of the baseball when the catcher gloves it 1.859 m above the ground is 10.74 m/s. To what height h did the ball rise?

6.98 A batter hits a pop-up straight up in the air from a height of 1.273 m. The baseball rises to a height of 7.777 m above the ground. The speed of the baseball when the catcher gloves it is 10.73 m/s. At what height above the ground did the catcher glove the ball?

6.99 A ball is thrown horizontally from the top of a building that is 20.27 m high with a speed of 24.89 m/s. Neglecting air resistance, at what angle with respect to the horizontal will the ball strike the ground?

6.100 A ball is thrown horizontally from the top of a building that is 26.01 m high. The ball strikes the ground at an angle of 41.86° with respect to the horizontal. Neglecting air resistance, with what speed was the ball thrown?

6.101 A ball is thrown horizontally from the top of a building with a speed of 25.51 m/s. The ball strikes the ground at an angle of 44.37° with respect to the horizontal. What is the height of the building?

Supertankers for transporting oil around the world are the largest ships ever built (Figure 7.1). They can have a mass (including cargo) of up to 650,000 tons and carry over 2 million barrels (84 million gallons = 318 million liters) of oil. However, their large size creates practical problems. Supertankers are too big to enter most shipping ports and have to stop at offshore platforms to offload their oil. In addition, piloting a ship of this size is extremely difficult. For example, when the captain gives the order to reverse engines and come to a stop, the ship can continue to move forward for more than 3 miles!

FIGURE 7.1 A supertanker.

Malcolm Fife/Getty Images

The physical quantity that makes a large moving object difficult to stop is *momentum*, the subject of this chapter. Momentum is a fundamental property associated with an object's motion, similar to kinetic energy. Moreover, both momentum and energy are subjects of important conservation laws in physics. However, momentum is a vector quantity, whereas energy is a scalar. Thus, working with momentum requires taking account of angles and components, as we did for force in Chapter 4.

The importance of momentum becomes most evident when we deal with collisions between two or more objects. In this chapter, we examine various collisions in one and two dimensions. In later chapters, we will make use of conservation of momentum in many different situations on vastly different scales —from bursts of elementary particles to collisions of galaxies.

WHAT WE WILL LEARN

- The momentum of an object is the product of its velocity and mass. Momentum is a vector quantity and points in the same direction as the velocity vector.
- Newton's Second Law can be phrased more generally as follows: The net force on an object equals the time derivative of the object's momentum.
- A change of momentum, called *impulse,* is the time integral of the net force that causes the momentum change.
- In all collisions, the momentum is conserved.
- Besides conservation of momentum, elastic collisions also have the property that the total kinetic energy is conserved.
- In totally inelastic collisions, the maximum amount of kinetic energy is removed, and the colliding objects stick to each other. Total kinetic energy is not conserved, but momentum is.
- Collisions that are neither elastic nor totally inelastic are partially inelastic, and the change in kinetic energy is proportional to the square of the coefficient of restitution.
- Momentum conservation is applied in such far-reaching fields as particle physics, where it is used in the discovery of new particles, and chaos theory, where it is used to show that it is impossible to predict long-term weather patterns.

7.1 Linear Momentum

For the terms *force, position, velocity,* and *acceleration,* the precise physical definitions are quite close to the words' usage in everyday language. With the term *momentum,* the situation is more analogous to that of *energy,* for which there is only a vague connection between conversational use and precise physical meaning. You sometimes hear that the campaign of a particular political candidate gains momentum or that legislation gains momentum in Congress. Often, sports teams or individual players are said to gain or lose momentum. What these statements imply is that the objects said to gain momentum have become harder to stop. However, Figure 7.2 shows that even objects with large momentum can be stopped!

FIGURE 7.2 Rocket-sled crash test of a fighter plane. Tests like these can be used to improve the design of critical structures such as nuclear reactors so that they can withstand the impact of a plane crash.

Definition of Momentum

In physics, **momentum** is defined as the product of an object's mass and its velocity:

$$\vec{p} = m\vec{v}. \tag{7.1}$$

As you can see, the lowercase letter $\vec{p}$ is the symbol for linear momentum. The velocity $\vec{v}$ is a vector and is multiplied by a scalar quantity, the mass m. The product is thus a vector as well. The momentum vector, $\vec{p}$, and the velocity vector, $\vec{v}$, are parallel to each other; that is, they point in the same direction. As a simple consequence of equation 7.1, the magnitude of the momentum is

$$p = mv.$$

The momentum is also referred to as *linear momentum* to distinguish it from angular momentum, a concept we will study in Chapter 10 on rotation. The units of momentum are kg m/s. Unlike the unit for energy, the unit for momentum does not have a special name. The magnitude of momentum spans a large range. Momenta of various objects, from a subatomic particle to a planet orbiting the Sun, are given in Table 7.1.

Table 7.1 **Momenta of Various Objects**

Object	Momentum (kg m/s)
Alpha (α) particle from ^{238}U decay	$9.53 \cdot 10^{-20}$
90-mph fastball	5.75
Charging rhinoceros	$3 \cdot 10^{4}$
Car moving on freeway	$5 \cdot 10^{4}$
Supertanker at cruising speed	$4 \cdot 10^{9}$
Moon orbiting Earth	$7.54 \cdot 10^{25}$
Earth orbiting Sun	$1.78 \cdot 10^{29}$

Momentum and Force

Let's take the time derivative of equation 7.1. We use the product rule of differentiation to obtain

$$\frac{d}{dt}\vec{p} = \frac{d}{dt}\left(m\vec{v}\right) = m\frac{d\vec{v}}{dt} + \frac{dm}{dt}\vec{v}.$$

For now, we assume that the mass of the object does not change, and therefore the second term is zero. Because the time derivative of the velocity is the acceleration, we have

$$\frac{d}{dt}\vec{p} = m\frac{d\vec{v}}{dt} = m\vec{a} = \vec{F},$$

according to Newton's Second Law. The relationship

$$\vec{F} = \frac{d}{dt}\vec{p} \tag{7.2}$$

is an equivalent form of Newton's Second Law. This form is more general than $\vec{F} = m\vec{a}$ because it also holds in cases where the mass is not constant in time. This distinction will become important when we examine rocket motion in Chapter 8. Because equation 7.2 is a vector equation, we can also write it in Cartesian components:

$$F_x = \frac{dp_x}{dt};\ F_y = \frac{dp_y}{dt};\ F_z = \frac{dp_z}{dt}.$$

Concept Check 7.1

A typical scene from a Saturday afternoon college football game: A linebacker of mass 95 kg runs with a speed of 7.8 m/s, and a wide receiver of mass 74 kg runs with a speed of 9.6 m/s. We denote the magnitudes of the momentum and the kinetic energy of the linebacker by p_l and K_l, respectively, and the magnitudes of the momentum and the kinetic energy of the wide receiver by p_w and K_l . Which set of inequalities is correct?

a) $p_l > p_w, K_l > K_w$

b) $p_l < p_w, K_l > K_w$

c) $p_l > p_w, K_l < K_w$

d) $p_l < p_w, K_l < K_w$

Momentum and Kinetic Energy

In Chapter 5, we established the relationship, $K = \frac{1}{2}mv^2$ (equation 5.1), between the kinetic energy K, the speed v, and the mass m. We can use $p = mv$ to obtain

$$K = \frac{mv^2}{2} = \frac{m^2v^2}{2m} = \frac{p^2}{2m}.$$

This equation gives us an important relationship between kinetic energy, mass, and momentum:

$$K = \frac{p^2}{2m}. \qquad (7.3)$$

At this point, you may wonder why we need to reformulate the concepts of force and kinetic energy in terms of momentum. This reformulation is far more than a mathematical game. We will see that momentum is conserved in collisions and disintegrations, and this principle will provide an extremely helpful way to find solutions to complicated problems. These relationships of momentum with force and kinetic energy will be very useful in working such problems. First, though, we need to explore the physics of changing momentum in a little more detail.

7.2 Impulse

The change in momentum is defined as the difference between the final (index f) and initial (index i) momenta:

$$\Delta\vec{p} \equiv \vec{p}_{\mathrm{f}} - \vec{p}_{\mathrm{i}}.$$

To see why this definition is useful, we have to do a bit of math. Let's start by exploring the relationship between force and momentum just a little further. We can integrate each component of the equation $\vec{F} = d\vec{p}/dt$ over time. For the integral of F_x, for example, we obtain:

$$\int_{t_{\mathrm{i}}}^{t_{\mathrm{f}}} F_x dt = \int_{t_{\mathrm{i}}}^{t_{\mathrm{f}}} \frac{dp_x}{dt} dt = \int_{p_{x,\mathrm{i}}}^{p_{x,\mathrm{f}}} dp_x = p_{x,\mathrm{f}} - p_{x,\mathrm{i}} \equiv \Delta p_x.$$

This equation requires some explanation. In the second step, we performed a substitution of variables to transform an integration over time into an integration over momentum. Figure 7.3a illustrates this relationship: The area under the $F_x(t)$ curve is the change in momentum, Δp_x. We can obtain similar equations for the y- and z-components.

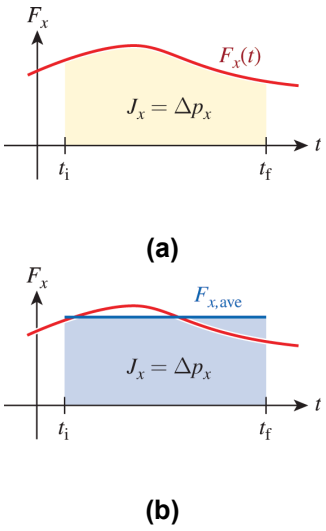

FIGURE 7.3 (a) The impulse (yellow area) is the time integral of the force; (b) same impulse resulting from an average force.

Combining all three component equations into one vector equation yields the following result:

$$\int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F} dt = \int_{t_\mathrm{i}}^{t_\mathrm{f}} \frac{d\overrightarrow{p}}{dt} dt = \int_{\overrightarrow{p}_\mathrm{i}}^{\overrightarrow{p}_\mathrm{f}} d\overrightarrow{p} = \overrightarrow{p}_\mathrm{f} - \overrightarrow{p}_\mathrm{i} \equiv \Delta\overrightarrow{p}.$$

The time integral of the force is called the **impulse**, $\overrightarrow{J}$:

$$\overrightarrow{J} \equiv \int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F} dt. \tag{7.4}$$

This definition immediately gives us the relationship between the impulse and the momentum change:

$$\overrightarrow{J} = \Delta\overrightarrow{p}. \tag{7.5}$$

From equation 7.5, we can calculate the momentum change over some time interval, if we know the time dependence of the force. If the force is constant or has some form that we can integrate, then we can simply evaluate the integral of equation 7.4. However, we can also define an average force,

$$\overrightarrow{F}_\mathrm{ave} = \frac{\displaystyle\int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F} dt}{\displaystyle\int_{t_\mathrm{i}}^{t_\mathrm{f}} dt} = \frac{1}{t_\mathrm{f} - t_\mathrm{i}} \int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F} dt = \frac{1}{\Delta t} \int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F} dt. \tag{7.6}$$

This integral gives us

$$\overrightarrow{J} = \overrightarrow{F}_\mathrm{ave}\, \Delta\, t. \tag{7.7}$$

You may think this transformation is trivial in that it conveys the same information as equation 7.5. After all, the integration is still there, hidden in the definition of the average force. This is true, but sometimes we are only interested

in the average force. Measuring the time interval, Δt, over which a force acts as well as the resulting impulse an object receives tells us the average force that the object experiences during that time interval. Figure 7.3b illustrates the relationship between the time-averaged force, the momentum change, and the impulse.

EXAMPLE 7.1 Baseball Home Run

A Major League pitcher throws a fastball that crosses home plate with a speed of 90.0 mph (40.23 m/s) and an angle of 5.0° below the horizontal. A batter slugs it for a home run, launching it with a speed of 110.0 mph (49.17 m/s) at an angle of 35.0° above the horizontal (Figure 7.4). The mass of a baseball is required to be between 5 and 5.25 oz; let's say that the mass of the ball hit here is 5.10 oz (0.145 kg).

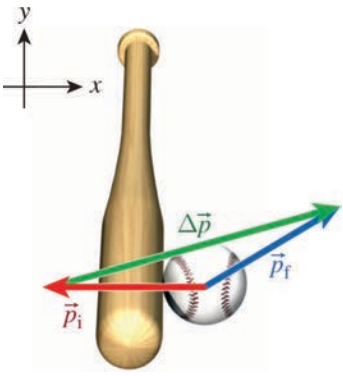

FIGURE 7.4 Baseball being hit by a bat. Initial (red) and final (blue) momentum vectors, as well as the impulse (green) vector (or change in momentum vector) are shown.

PROBLEM 1

What is the magnitude of the impulse the baseball receives from the bat?

SOLUTION 1

The impulse is equal to the momentum change of the baseball. Unfortunately, there is no shortcut; we must calculate $\Delta\vec{v} \equiv \vec{v}_f - \vec{v}_i$ for the x- and y-components separately, add them as vectors, and finally multiply by the mass of the baseball:

$$\Delta v_x = (49.17\ \text{m/s})(\cos 35.0^\circ) - (40.23\ \text{m/s})(\cos 185.0^\circ) = 80.35\ \text{m/s}$$
$$\Delta v_y = (49.17\ \text{m/s})(\sin 35.0^\circ) - (40.23\ \text{m/s})(\sin 185.0^\circ) = 31.71\ \text{m/s}$$
$$\Delta v = \sqrt{\Delta v_x^2 + \Delta v_y^2} = \sqrt{(80.35)^2 + (31.71)^2}\text{m/s} = 86.38\ \text{m/s}$$
$$\Delta p = m\,\Delta\, v = (0.145\ \text{kg})(86.38\ \text{m/s}) = 12.5\ \text{kg m/s}.$$

Avoiding a Common Mistake

It is tempting to just add the magnitudes of the initial and final momentum vectors, because they point approximately in opposite directions. This method would lead to $\Delta p_{\text{wrong}} = m(v_1 + v_2) = 12.96 \text{ kg m/s}$. As you can see, this answer is pretty close to the correct one, only about 3% off. It can serve as a first estimate, if you realize that the vectors point in almost opposite directions and that, in such a case, vector subtraction implies an addition of the two magnitudes. However, to get the correct answer, you have to go through the calculations above.

PROBLEM 2

High-speed video shows that the ball-bat contact lasts only about 1 ms (0.001 s). Suppose, for the home run we're considering, that the contact lasted 1.20 ms. What was the magnitude of the average force exerted on the ball by the bat during that time?

SOLUTION 2

The force can be calculated by simply using the formula for the impulse:

$$\Delta\vec{p} = \vec{J} = \vec{F}_{\text{ave}}\,\Delta t$$
$$\Rightarrow F_{\text{ave}} = \frac{\Delta p}{\Delta t} = \frac{12.5\,\text{kg m/s}}{0.00120\text{ s}} = 10.4\text{ kN}.$$

This force is approximately the same as the weight of an entire baseball team! The collision of the bat and the ball results in significant compression of the baseball, as shown in Figure 7.5.

FIGURE 7.5 A baseball being compressed as it is hit by a baseball bat.

Tetra Images/Brand X Pictures/Getty Images

Concept Check 7.2

If the baseball in Example 7.1 was hit so that it had the same speed of 110 mph after it left the bat but was launched at an angle of 38° above the horizontal, the impulse the baseball received would have been

a) bigger.

b) smaller.

c) the same.

Self-Test Opportunity 7.1

Can you think of other everyday articles that are designed to minimize the average force for a given impulse?

Some important safety devices, such as air bags and seat belts in cars, make use of equation 7.7 relating impulse, average force, and time. If the car you are driving has a collision with another vehicle or a stationary object, the impulse—that is, the momentum change of your car—is rather large, and it can be delivered over a very short time interval. Equation 7.7 then results in a very large average force:

$$\vec{F}_{\text{ave}} = \frac{\vec{J}}{\Delta t}.$$

If no seat belts or air bags were installed in your car, a sudden stop could cause your head to hit the windshield and experience the impulse during a very short time of only a few milliseconds. This could result in a big average force acting on your head, causing injury or even death. Air bags and seat belts are designed to make the time over which the momentum change occurs as long as possible. Maximizing this time and having the driver's body decelerate in contact with the air bag minimize the force acting on the driver, greatly reducing injuries (see Figure 7.6).

FIGURE 7.6 Time sequence of a crash test, showing the role of air bags, seat belts, and crumple zones in reducing the forces acting on the driver during a crash. The air bag can be seen deploying in the second photograph of the sequence.

Photron

Concept Check 7.3

Several cars are designed with active crumple zones in the front that get severely damaged during head-on collisions. The purpose of this design is to

a) reduce the impulse experienced by the driver during the collision.

b) increase the impulse experienced by the driver during the collision.

c) reduce the collision time and thus reduce the force acting on the driver.

d) increase the collision time and thus reduce the force acting on the driver.

e) make the repair as expensive as possible.

SOLVED PROBLEM 7.1 Egg Drop

PROBLEM

An egg in a special container is dropped from a height of 3.70 m. The container and egg together have a mass of 0.144 kg. A net force of 4.42 N will break the egg. What is the minimum time over which the egg/container can come to a stop without breaking the egg?

SOLUTION

THINK

When the egg/container is released, it accelerates with the acceleration due to gravity. When the egg/container strikes the ground, its velocity goes from the final velocity due to the gravitational acceleration to zero. As the egg/container comes to a stop, the force stopping it times the time interval (the impulse) will equal the mass of the egg/container times the change in speed. The time interval over which the velocity change takes place will determine whether the force exerted on the egg by the collision with the floor will break the egg.

SKETCH

The egg/container is dropped from rest from a height of h = 3.70 m (Figure 7.7).

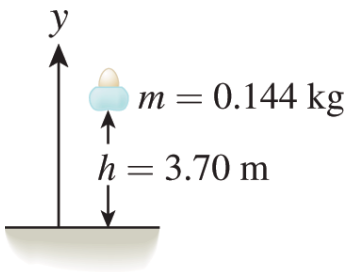

FIGURE 7.7 An egg in a special container is dropped from a height of 3.70 m.

RESEARCH

From the discussion of kinematics in Chapter 2, we know the final speed, v_y, of the egg/container resulting from free fall from a height of $y0$ to a final height of y, starting with an initial velocity v_{y0}, is given by

$$v_y^2 = v_{y0}^2 - 2g(y - y_0). \qquad \text{(i)}$$

We know that $v_{y0} = 0$ because the egg/container was released from rest. We define the final height to be y = 0 and the initial height to be $y_0 = h$, as shown in Figure 7.7. Thus, equation (i) for the final speed in the y-direction reduces to

$$v_y = \sqrt{2gh}. \qquad \text{(ii)}$$

When the egg/container strikes the ground, the impulse, $\vec{J}$ exerted on it is given by

$$\vec{J} = \Delta\vec{P} = \int_{t_1}^{t_2} \vec{F} dt, \qquad \text{(iii)}$$

where $\Delta\vec{P}$ is the change in momentum of the egg/container and $\vec{F}$ is the force exerted to stop it. We assume the force is constant, so we can rewrite the integral in equation (iii) as

$$\int_{t_1}^{t_2} \vec{F} dt = \vec{F}(t_2 - t_1) = \vec{F}\,\Delta\, t.$$

The momentum of the egg/container will change from $p = mv_y$ to p = 0 when it strikes the ground, so we can write

$$\Delta p_y = 0 - (-mv_y) = mv_y = F_y\,\Delta\, t, \qquad \text{(iv)}$$

where the term $-mv_y$ is negative because the velocity of the egg/container just before impact is in the negative y-direction.

SIMPLIFY

We can now solve equation (iv) for the time interval and substitute the expression for the final velocity from equation (ii):

$$\Delta t = \frac{mv_y}{F_y} = \frac{m\sqrt{2gh}}{F_y}. \qquad \text{(v)}$$

CALCULATE

Inserting the numerical values, we get

$$\Delta t = \frac{(0.144\ \text{kg})\sqrt{2(9.81\text{m/s}^2)(3.70\text{m})}}{4.42\text{N}} = 0.277581543\ \text{s}.$$

ROUND

All of the numerical values in this problem were given with three significant figures, so we report our answer as

$$\Delta t = 0.278\ \text{s}.$$

DOUBLE-CHECK

Slowing the egg/container from its final velocity to zero over a time interval of 0.278 s seems reasonable. Looking at equation (v) we see that the force exerted on the egg as it hits the ground is given by

$$F = \frac{mv_y}{\Delta t}.$$

For a given height, we could reduce the force exerted on the egg in several ways. First, we could make Δt larger by making some kind of crumple zone in the container. Second, we could make the egg/container as light as possible. Third, we could construct the container so that it had a large surface area and thus significant air resistance, which would reduce the value of v_y below that for frictionless free fall.

7.3 Conservation of Linear Momentum

Suppose two objects collide with each other. They might then rebound away from each other, like two billiard balls on a billiard table. This kind of collision is called an **elastic collision** (at least it is approximately elastic, as we will see later). Another example of a collision is that of a subcompact car with an 18-wheeler, where the two vehicles stick to each other. This kind of collision is called a **totally inelastic collision**. Before seeing exactly what is meant by the terms *elastic* and *inelastic collisions,* let's look at the momenta, $\overrightarrow{p_1}$ and $\overrightarrow{p_2}$, of two objects during a collision.

We find that the sum of the two momenta after the collision is the same as the sum of the two momenta before the collision (index i1 indicates the initial value for object 1, just before the collision, and index f1 indicates the final value for the same object):

$$\overrightarrow{p_{\text{f1}}} + \overrightarrow{p_{\text{f2}}} = \overrightarrow{p_{\text{i1}}} + \overrightarrow{p_{\text{i2}}}. \tag{7.8}$$

This equation is the basic expression of the law of **conservation of total momentum**, the most important result of this chapter and the second conservation law we have encountered (the first being the law of conservation of energy in Chapter 6). Let's first go through its derivation and then consider its consequences.

DERIVATION 7.1

During a collision, object 1 exerts a force on object 2. Let's call this force $\overrightarrow{F}_{1\to 2}$. Using the definition of impulse and its relationship to the momentum change, we get for the momentum change of object 2 during the collision:

$$\int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F}_{1\to 2} dt = \Delta\overrightarrow{p}_2 = \overrightarrow{p}_{\mathrm{f}2} - \overrightarrow{p}_{\mathrm{i}2}.$$

Here we neglect external forces; if they exist, they are usually negligible compared to $\overrightarrow{F}_{1\to 2}$ during the collision. The initial and final times are selected to bracket the time of the collision process. In addition, the force $\overrightarrow{F}_{2\to 1}$, which object 2 exerts on object 1, is also present. The same argument as before leads to

$$\int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F}_{2\to 1} dt = \Delta\overrightarrow{p}_1 = \overrightarrow{p}_{\mathrm{f}1} - \overrightarrow{p}_{\mathrm{i}1}.$$

Newton's Third Law (see Chapter 4) tells us that these forces are equal and opposite to each other, $\overrightarrow{F}_{1\to 2} = \overrightarrow{F}_{2\to 1,}$ or

$$\overrightarrow{F}_{1\to 2} + \overrightarrow{F}_{2\to 1} = 0.$$

Integration of this equation results in

$$0 = \int_{t_\mathrm{i}}^{t_\mathrm{f}} \left(\overrightarrow{F}_{2\to 1} + \overrightarrow{F}_{1\to 2}\right) dt = \int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F}_{2\to 1} dt + \int_{t_\mathrm{i}}^{t_\mathrm{f}} \overrightarrow{F}_{2\to 1} dt = \overrightarrow{p}_{\mathrm{f}1} - \overrightarrow{p}_{\mathrm{i}1} + \overrightarrow{p}_{\mathrm{f}2} -$$

Collecting the initial momentum vectors on one side and the final momentum vectors on the other gives us equation 7.8:

$$\overrightarrow{p}_{\mathrm{f}1} + \overrightarrow{p}_{\mathrm{f}2} = \overrightarrow{p}_{\mathrm{i}1} + \overrightarrow{p}_{\mathrm{i}2}.$$

Equation 7.8 expresses the principle of conservation of linear momentum. The sum of the final momentum vectors is exactly equal to the sum of the initial momentum vectors. Note that this equation does not depend on any particular conditions for the collision. It is valid for all two-body collisions, elastic or inelastic.

You may object that other external forces may be present. In a collision of billiard balls, for example, there is a friction force due to each ball rolling or sliding across the table. In a collision of two cars, friction acts between the tires and the road. However, what characterizes a collision is the occurrence of a very large impulse due to a very large contact force during a relatively short time. If you integrate the external forces over the collision time, you obtain only very small or moderate impulses. Thus, these external forces can usually be safely neglected in calculations of collision dynamics, and we can treat two-body collisions as if only internal forces are at work. We will assume we are dealing with an isolated system, which is a system with no external forces.

In addition, the same argument holds if there are more than two objects taking part in the collision or if there is no collision at all. As long as the net external force is zero, the total momentum of the interaction of objects will be conserved:

$$\overrightarrow{F}_{\text{net}} = 0 \text{ then } \sum_{k=1}^{n} \overrightarrow{pk} = \text{constant}. \qquad \textbf{(7.9)}$$

Equation 7.9 is the general formulation of the law of conservation of momentum. We will return to this general formulation in Chapter 8 when we talk about systems of particles. For the remainder of this chapter, we consider only idealized cases in which the net external force is negligibly small, and thus the total momentum is always conserved in all processes.

7.4 Elastic Collisions in One Dimension

Figure 7.8 shows the collision of two carts on an almost frictionless track. The collision was videotaped, and the figure includes seven frames of this video, taken at intervals of 0.06 s. The cart marked with the green circle is initially at rest. The cart marked with the orange square has a larger mass and is approaching from the left. The collision happens in the frame marked with the time t = 0.12 s. You can see that after the collision, both carts move to the right, but the lighter cart moves with a significantly higher speed. (The speed is proportional to the horizontal distance between the carts' markings in adjacent video frames.) Next, we'll derive equations that can be used to determine the velocities of the carts after the collision.

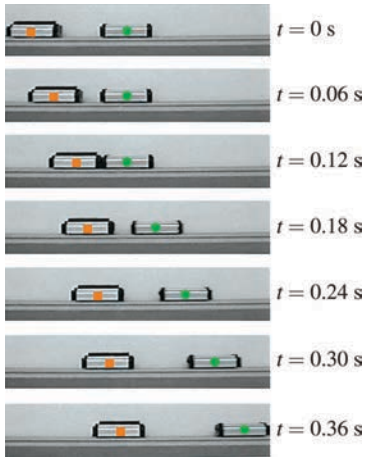

FIGURE 7.8 Video sequence of a collision between two carts of nonequal masses on an air track. The cart with the orange square carries a black metal bar to increase its mass.

W. Bauer and G. D. Westfall

What exactly is an elastic collision? As with so many concepts in physics, it is an idealization. In practically all collisions, at least some kinetic energy is converted into other forms of energy that are not conserved. The other forms can be heat or sound or the energy to deform an object, for example. However, an elastic collision is defined as one in which the total kinetic energy of the colliding objects is conserved. This definition does not mean that each object involved in the collision retains its kinetic energy. Kinetic energy can be transferred from one

object to the other, but *in an elastic collision, the sum of the kinetic energies has to remain constant.*

We'll consider objects moving in one dimension and use the notations $p_{\mathrm{i}1,x}$ for the initial momentum and $p_{\mathrm{f}1,x}$ for the final momentum of object 1. (We use the subscript *x* to remind ourselves that these could equally well be the *x*-components of the two- or three-dimensional momentum vector.) In the same way, we denote the initial and final momenta of object 2 by $p_{\mathrm{i}2,x}$ and $p_{\mathrm{f}2,x}$. Because we are restricted to collisions in one dimension, the equation for conservation of kinetic energy can be written as

$$\frac{p_{\mathrm{f}1,x}^2}{2m_1} + \frac{p_{\mathrm{f}2,x}^2}{2m_2} = \frac{p_{\mathrm{i}1,x}^2}{2m_1} + \frac{p_{\mathrm{i}2,x}^2}{2m_2}. \qquad \textbf{(7.10)}$$

(For motion in one dimension, the square of the *x*-component of the vector is also the square of the absolute value of the vector.) The equation for conservation of momentum in the *x*-direction can be written as

$$p_{\mathrm{f}1,x} + p_{\mathrm{f}2,x} = p_{\mathrm{i}1,x} + p_{\mathrm{i}2,x}. \qquad \textbf{(7.11)}$$

(Remember that momentum is conserved in any collision in which the external forces are negligible.)

Let's look more closely at equations 7.10 and 7.11. What is known, and what is unknown? Typically, we know the two masses and components of the initial momentum vectors, and we want to find the final momentum vectors after the collision. This calculation can be done because equations 7.10 and 7.11 give us two equations for two unknowns, $p_{\mathrm{f}1,x}$ and $p_{\mathrm{f}2,x}$. This is by far the most common use of these equations, but it is also possible, for example, to calculate the two masses if the initial and final momentum vectors are known.

Let's find the components of the final momentum vectors:

$$\begin{aligned} p_{\mathrm{f}1,x} &= \left(\frac{m_1 - m_2}{m_1 + m_2}\right) p_{\mathrm{i}1,x} + \left(\frac{2m_1}{m_1 + m_2}\right) p_{\mathrm{i}2,x} \\ p_{\mathrm{f}2,x} &= \left(\frac{2m_2}{m_1 + m_2}\right) p_{\mathrm{i}1,x} + \left(\frac{m_2 - m_1}{m_1 + m_2}\right) p_{\mathrm{i}2,x}. \end{aligned} \qquad \textbf{(7.12)}$$

Derivation 7.2 shows how this result is obtained. It will help you solve similar problems.

DERIVATION 7.2

We start with the equations for energy and momentum conservation and collect all quantities connected with object 1 on the left side and all those connected with object 2 on the right. Equation 7.10 for the (conserved) kinetic energy then becomes:

$$\frac{p_{\mathrm{f1},x}^2}{2m_1} - \frac{p_{\mathrm{i1},x}^2}{2m_1} = \frac{p_{\mathrm{i2},x}^2}{2m_2} - \frac{p_{\mathrm{f2},x}^2}{2m_2}$$

or

$$m_2\left(p_{\mathrm{f1},x}^2 - p_{\mathrm{i1},x}^2\right) = m_1\left(p_{\mathrm{f2},x}^2 - p_{\mathrm{i2},x}^2\right). \qquad \text{(i)}$$

Page 203

By rearranging equation 7.11 for momentum conservation, we obtain

$$p_{\mathrm{f1},x} - p_{\mathrm{i1},x} = p_{\mathrm{i2},x} - p_{\mathrm{f2},x}. \qquad \text{(ii)}$$

Next, we divide the left and right sides of equation (i) by the corresponding sides of equation (ii). To do this division, we use the algebraic identity $a^2 - b^2 = (a + b)(a - b)$. This process results in

$$m_2(p_{\mathrm{i1},x} + p_{\mathrm{f1},x}) = m_1(p_{\mathrm{i2},x} + p_{\mathrm{f2},x}). \qquad \text{(iii)}$$

Now we can solve equation (ii) for $p_{\mathrm{f1,x}}$ and substitute the expression $p_{\mathrm{i1},x} + p_{\mathrm{i2},x} - p_{\mathrm{f2},x}$ into equation (iii):

$$\begin{aligned} m_2(p_{\mathrm{i1},x} + [p_{\mathrm{i1},x} + p_{\mathrm{i2},x} - p_{\mathrm{f2},x}]) &= m_1(p_{\mathrm{i2},x} + p_{\mathrm{f2},x}) \\ 2m_2p_{\mathrm{i1},x} + m_2p_{\mathrm{i2},x} - m_2p_{\mathrm{f2},x} &= m_1p_{\mathrm{i2},x} + m_1p_{\mathrm{f2},x} \\ p_{\mathrm{f2},x}(m_1 + m_2) &= 2m_2p_{\mathrm{i1},x} + (m_2 - m_1)p_{\mathrm{i2},x} \\ p_{\mathrm{f2},x} &= \frac{2m_2p_{\mathrm{i1},x} + (m_2 - m_1)p_{\mathrm{i2},x}}{m_1 + m_2} \end{aligned}$$

This result is one of the two desired components of equation 7.12. We can obtain the other component by solving equation (ii) for $p_{\mathrm{f2,x}}$ and substituting the expression $p_{\mathrm{i1},x} + p_{\mathrm{i2},x} - p_{\mathrm{f2},x}$ into equation (iii). We can also obtain the

result for $p_{\mathrm{f1},x}$ from the result for $p_{\mathrm{f2},x}$ that we just derived by exchanging the indices 1 and 2. It is, after all, arbitrary which object is labeled 1 or 2, and so the resulting equations should be symmetric under the exchange of the two labels. Use of this type of symmetry principle is very powerful and very convenient. (But it does take some getting used to at first!)

With the result for the final momenta, we can also obtain expressions for the final velocities by using $p_x = mv_x$:

$$\begin{aligned} v_{\mathrm{f1},x} &= \left(\frac{m_1 - m_2}{m_1 + m_2}\right) v_{\mathrm{i1},x} + \left(\frac{2m_2}{m_1 + m_2}\right) v_{\mathrm{i2},x} \\ v_{\mathrm{f2},x} &= \left(\frac{2m_1}{m_1 + m_2}\right) v_{\mathrm{i1},x} + \left(\frac{m_2 - m_1}{m_1 + m_2}\right) v_{\mathrm{i2},x}. \end{aligned} \tag{7.13}$$

These equations for the final velocities look, at first sight, very similar to those for the final momenta (equation 7.12). However, there is one important difference: In the second term of the right-hand side of the equation for $v_{\mathrm{f1},x}$ the numerator is $2m_2$ instead of $2m_1$; and conversely, the numerator is now $2m_1$ instead of $2m_2$ in the first term of the equation for $v_{\mathrm{f2,x}}$.

As a last point in this general discussion, let's find the relative velocity, $v_{\mathrm{f1,x}} - v_{\mathrm{f2,x}}$, after the collision:

$$\begin{aligned} v_{\mathrm{f1,x}} - v_{\mathrm{f2,x}} &= \left(\frac{m_1 - m_2 - 2m_1}{m_1 + m_2}\right) v_{\mathrm{i1,x}} + \left(\frac{2m_2 - (m_2 - m_1)}{m_1 + m_2}\right) v_{\mathrm{i2,x}} \\ &= -v_{\mathrm{i1,x}} + v_{\mathrm{i2,x}} = (v_{\mathrm{i1,x}} - v_{\mathrm{i2,x}}). \end{aligned} \tag{7.1}$$

We see that *in elastic collisions, the relative velocity simply changes sign,* $\Delta v_f = -\Delta v_i$. We will return to this result later in this chapter. You should not try to memorize the general expressions for momentum and velocity in equations 7.13 and 7.14, but instead study the method we used to derive them. Next, we examine two special cases of these general results.

Special Case 1: Equal Masses

If $m_1 = m_2$, the general expressions in equation 7.12 simplify considerably, because the terms proportional to $m_1 - m_2$ are equal to zero and the ratios $2m_1/(m_1 + m_2)$ and $2m_2/(m_1 + m_2)$ become unity. We then obtain the extremely simple result

$$\begin{aligned} p_{\mathrm{f1},x} &= p_{\mathrm{i1},x} \\ p_{\mathrm{f2},x} &= p_{\mathrm{i2},x}. \end{aligned} \qquad (\text{for the special case where } m_1 = m_2) \qquad \textbf{(7.15)}$$

This result means that in any elastic collision of two objects of equal mass moving in one dimension, the two objects simply *exchange* their momenta. The initial momentum of object 1 becomes the final momentum of object 2. The same is true for the velocities:

$$\begin{matrix} v_{f1,x} \\ v_{f2,x} \end{matrix} (for\ the\ special\ case\ where\ m_1 = m_2) \qquad \textbf{(7.16)}$$

Special Case 2: One Object Initially at Rest

Now suppose the two objects in a collision are not necessarily the same in mass, but one of the two is initially at rest, that is, has zero momentum. Without loss of generality, we can say that object 1 is the one at rest. (Remember that the equations are invariant under exchange of the indices 1 and 2.) By using the general expressions in equation 7.12 and setting $p_{\mathrm{i1,x=0}}$, we get

$$p_{\mathrm{f1},x} = \left(\frac{2m_1}{m_1 + m_2}\right) p_{\mathrm{i2},x}$$

$$p_{\mathrm{f2},x} = \left(\frac{m_2 - m_1}{m_1 + m_2}\right) p_{\mathrm{i2},x}$$

(for the special case where $p_{\mathrm{i1},x} = 0$). **(7.17)**

In the same way, we obtain for the final velocities

$$v_{\mathrm{f1},x} = \left(\frac{2m_2}{m_1 + m_2}\right) v_{\mathrm{i2},x}$$

$$v_{\mathrm{f2},x} = \left(\frac{m_2 - m_1}{m_1 + m_2}\right) v_{\mathrm{i2},x}$$

(for the special case where $p_{\mathrm{i1},x} = 0$). **(7.18)**

If $v_{\mathrm{i2},x} > 0$, object 2 moves from left to right, with the conventional assignment of the positive x-axis pointing to the right. This situation is shown in Figure 7.8. Depending on which mass is larger, the collision can have one of four outcomes:

1. $m_2 > m_1 \Rightarrow (m_2 - m_1)/(m_2 + m_1) > 0$: The final velocity of object 2 points in the same direction but is reduced in magnitude.
2. $m_2 = m_1 \Rightarrow (m_2 - m_1)/(m_2 + m_1) = 0$: Object 2 is at rest, and object 1 moves with the initial velocity of object 2.
3. $m_2 < m_1 \Rightarrow (m_2 - m_1)/(m_2 + m_1) < 0$: Object 2 bounces back; the direction of its velocity vector changes.
4. $m_2 \ll m_1 \Rightarrow (m_2 - m_1)/(m_2 + m_1) \approx -1 \; and \; 2m_2/(m_1 + m_2) \approx 0$: Object 1 remains at rest, and object 2 approximately reverses its velocity. This situation occurs, for example, in the collision of a ball with the ground. In this collision, object 1 is the entire Earth and object 2 is the ball. If the collision is sufficiently elastic, the ball bounces back with the same speed it had right before the collision, but in the opposite direction—up instead of down.

Concept Check 7.4

Suppose an elastic collision occurs in one dimension, like the one shown in Figure 7.8, where the cart marked with the green circle is initially at rest and the cart with the orange square initially has $V_{\text{orange}} > 0$, that is, is moving from left to right. What can you say about the masses of the two carts?

a) $m_{\text{orange}} < m_{\text{green}}$

b) $m_{\text{orange}} > m_{\text{green}}$

c) $m_{\text{orange}} = m_{\text{green}}$

Concept Check 7.5

In the situation shown in Figure 7.8, suppose the mass of the cart with the orange square is very much larger than that of the cart with the green circle. What outcome do you expect?

a) The outcome is about the same as the one shown in the figure.

b) The cart with the orange square moves with almost unchanged velocity after the collision, and the cart with the green circle moves with a velocity almost twice as large as the initial velocity of the cart with the orange square.

c) Both carts move with almost the same speed that the cart with the orange square had before the collision.

d) The cart with the orange square stops, and the cart with the green circle moves to the right with the same speed that the cart with the orange square had originally.

Concept Check 7.6

In the situation shown in Figure 7.8, if the mass of the cart with the green circle (originally at rest) is very much larger than that of the cart with the orange square, what outcome do you expect?

a) The outcome is about the same as shown in the figure.

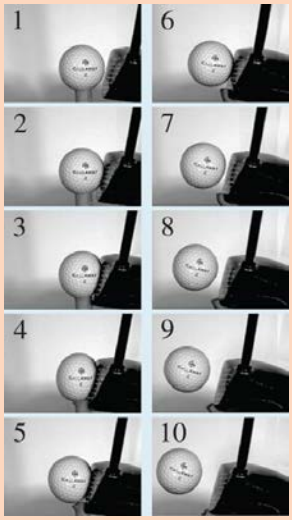
b) The cart with the orange square moves with an almost unchanged velocity after the collision, and the cart with the green circle moves with a velocity almost twice as large as the initial velocity of the cart with the orange square.

c) Both carts move with almost the same speed that the cart with the orange square had before the collision.

d) The cart with the green circle moves with a very low speed slightly to the right, and the cart with the orange square bounces back to the left with almost the same speed it had originally.

Self-Test Opportunity 7.2

The figure shows a high-speed video sequence of the collision of a golf club with a golf ball. The ball experiences significant deformation, but this deformation is sufficiently restored before the ball leaves the club's face. Thus, this collision can be approximated as a one-dimensional elastic collision. Discuss the speed of the ball relative to that of the club after the collision and how the cases we have discussed apply to this result.



Collision of a golf club with a golf ball.

Photron

EXAMPLE 7.2 Average Force on a Golf Ball

A driver is a golf club used to hit a golf ball a long distance. The head of a driver typically has a mass of 200. g. A skilled golfer can give the club head a speed of around 40.0 m/s. The mass of a golf ball is 45.0 g. The ball stays in contact with the face of the driver for 0.500 ms.

PROBLEM

What is the average force exerted on the golf ball by the driver?

SOLUTION

The golf ball is initially at rest. Because the driver head and the ball are in contact for only a short time, we can consider the collision between them to be an elastic collision. We can use equation 7.18 to calculate the speed of the golf ball, $v_{f1,x}$, after the collision with the driver head

$$v_{f1,x} = \left(\frac{2m_2}{m_1 + m_2}\right) v_{i2,x'}$$

where m_1 is the mass of the golf ball, m_2 is the mass of the driver head, and $v_{i2,x}$ is the speed of the driver head. The speed of the golf ball leaving the face of the driver head in this case is

$$v_{f1,x} = \frac{2(0.200\ \text{kg})}{0.0450\ \text{kg} + 0.200\ \text{kg}}(40.0\ \text{m/s}) = 65.3\ \text{m/s}.$$

Note that if the driver head were much more massive than the golf ball, the golf ball would attain twice the speed of the driver head. However, in that case, the golfer would have a difficult time giving the club head a substantial speed. The momentum change of the golf ball is

$$\Delta p = m\Delta v = mv_{f1,x}.$$

The impulse is then

$$\Delta p = F_{ave}\Delta t,$$

where F_{ave} is the average force exerted by the driver head and Δt is the time that the driver head and golf ball are in contact. The average force is then

$$F_{ave} = \frac{\Delta p}{\Delta t} = \frac{mv_{f1,x}}{\Delta t} = \frac{(0.045\ \text{kg})(65.3\ \text{m/s})}{0.500 \cdot 10^{-3}\ s} = 5880\ \text{N}.$$

Thus, the driver exerts a very large force on the golf ball. This force compresses the golf ball significantly, as shown in the video sequence in Self-Test Opportunity 7.2. Also, note that the driver does not propel the ball in the

horizontal direction and imparts spin to the ball. Thus, an accurate description of striking a golf ball with a driver requires a more detailed analysis.

7.5 Elastic Collisions in Two or Three Dimensions

Collisions with Walls

To begin our discussion of two- and three-dimensional collisions, we consider the elastic collision of an object with a solid wall. In Chapter 4 on forces, we saw that a solid surface exerts a force on any object that attempts to penetrate the surface. Such forces are normal forces; they are directed perpendicular to the surface (Figure 7.9). If a normal force acts on an object colliding with a wall, the normal force can only transmit an impulse that is perpendicular to the wall; the normal force has no component parallel to the wall. Thus, the momentum component of the object directed along the wall does not change, $p_{f,\parallel} = p_{i,\parallel}$. In addition, for an elastic collision, we have the condition that the kinetic energy of the object colliding with the wall has to remain the same. This makes sense because the wall stays at rest (it is connected to the Earth and has a much bigger mass than the ball). The kinetic energy of the object is $K = p^2/2m$, so we see that $P_f^2 = P_i^2$.

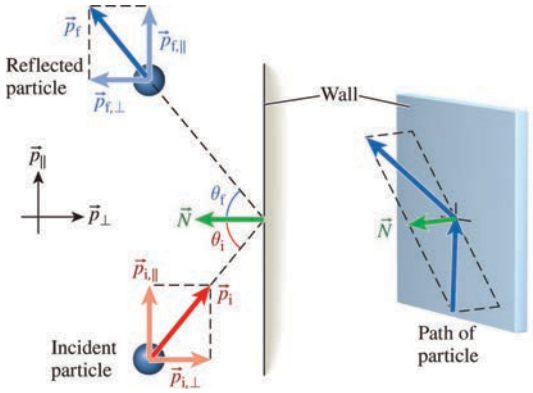


FIGURE 7.9 Elastic collision of an object with a wall. The symbol $\perp$ represents the component of the momentum perpendicular to the wall, and the symbol $\parallel$ represents the component of the momentum parallel to the wall.

Concept Check 7.7

Choose the correct statement:

a) In an elastic collision of an object with a wall, energy may or may not be conserved.

b) In an elastic collision of an object with a wall, momentum may or may not be conserved.

c) In an elastic collision of an object with a wall, the incident angle is equal to the final angle.

d) In an elastic collision of an object with a wall, the original momentum vector does not change as a result of the collision.

e) In an elastic collision of an object with a wall, the wall cannot change the momentum of the object because momentum is conserved.

Concept Check 7.8

Choose the correct statement:

a) When a moving object strikes a stationary object, the angle between the velocity vectors of the two objects after the collision is always 90°.

b) For a real-life collision between a moving object and a stationary object, the angle between the velocity vectors of the two objects after the collision is never less than 90°.

c) When a moving object has a head-on collision with a stationary object, the angle between the two velocity vectors after the collision is 90°.

d) When a moving object collides head-on and elastically with a stationary object of the same mass, the object that was moving stops and the other object moves with the original velocity of the moving object.

e) When a moving object collides elastically with a stationary object of the same mass, the angle between the two velocity vectors after the collision cannot be 90°.

Because $P_{\mathrm{f}}^2 = P_{\mathrm{f},\parallel}^2 + P_{\mathrm{f},\perp}^2$ and $P_{\mathrm{i}}^2 = P_{\mathrm{i},\parallel}^2 + P_{\mathrm{i},\perp}^2$, we get $P_{\mathrm{f},\perp}^2 = P_{\mathrm{i},\perp}^2$. The only two outcomes possible for the collision are then $P_{\mathrm{f}\perp} = P_{\mathrm{i}\perp}$ and $P_{\mathrm{f}\perp} = -P_{\mathrm{i}\perp}$. Only for the second solution does the perpendicular momentum component point away

from the wall after the collision, so it is the only solution that makes sense physically.

To summarize, when an object collides elastically with a wall, the length of the object's momentum vector remains unchanged, as does the momentum component directed along the wall; the momentum component perpendicular to the wall changes sign, but retains the same absolute value. The angle of incidence, θ_i, on the wall (Figure 7.9) is then also the same as the angle of reflection, θ_f:

$$\theta_i = \cos^{-1}\left(\frac{p_{i,\perp}}{p_i}\right) = \cos^{-1}\left(\frac{p_{f,\perp}}{p_f}\right) = \theta_f. \qquad \textbf{(7.19)}$$

We will see this same relationship again when we study light and its reflection off a mirror in Chapter 32.

Collisions of Two Objects in Two Dimensions

We have just seen that problems involving elastic collisions in one dimension are always solvable if we have the initial velocity or momentum conditions for the two colliding objects, as well as their masses. Again, this is true because we have two equations for the two unknown quantities, $P_{\mathrm{f1,x}}$ and $P_{\mathrm{f2,x}}$.

For collisions in two dimensions, each of the final momentum vectors has two components. Thus, this situation gives us four unknown quantities to determine. How many equations do we have at our disposal? Conservation of kinetic energy again provides one of them. Conservation of linear momentum provides independent equations for the *x*- and *y*-directions. Therefore, we have only three equations for the four unknown quantities. Unless an additional condition is specified for the collision, there is no unique solution for the final momenta.

For collisions in three dimensions, the situation is even worse. Here we need to determine two vectors with three components each, for a total of six unknown quantities. However, we have only four equations: one from energy conservation and three from the conservation equations for the *x-, y-,* and *z*-components of momentum.

Incidentally, this fact is what makes the game of billiards or pool interesting from a physics perspective. The final momenta of two balls after a collision are determined by where on their spherical surfaces they hit each other. Speaking of billiard ball collisions, an interesting observation can be made. Suppose object 2 is initially at rest and both objects have the same mass. Then conservation of momentum results in

$$\begin{aligned}\vec{p}_{\mathrm{f1}}+\vec{p}_{\mathrm{f2}}&=\vec{p}_{\mathrm{i1}}\\ \left(\vec{p}_{\mathrm{f1}}+\vec{p}_{\mathrm{f2}}\right)^2&=\left(\vec{p}_{\mathrm{i1}}\right)^2\\ p_{\mathrm{f1}}^2+p_{\mathrm{f2}}^2+2\vec{p}_{\mathrm{f1}}\bullet\vec{p}_{\mathrm{f2}}&=p_{\mathrm{il}}^2.\end{aligned}$$

Here we squared the equation for momentum conservation and then used the properties of the scalar product. On the other hand, conservation of kinetic energy leads to

$$\begin{aligned}\frac{p_{\mathrm{f1}}^2}{2m}+\frac{p_{\mathrm{f2}}^2}{2m}&=\frac{p_{\mathrm{il}}^2}{2m}\\ p_{\mathrm{f1}}^2+p_{\mathrm{f2}}^2&=p_{\mathrm{il}}^2,\end{aligned}$$

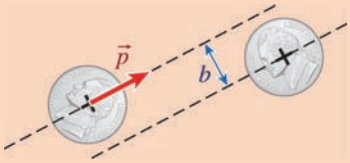
for $m_1=m_2\equiv m$. If we subtract this result from the previous result, we obtain

$$2\vec{p}_{\mathrm{f1}}\bullet\vec{p}_{\mathrm{f2}}=0. \qquad \textbf{(7.20)}$$

However, the scalar product of two vectors can be zero only if the two vectors are perpendicular to each other or if one of them has length zero. The latter condition is in effect in a head-on collision of two billiard balls, after which the cue ball remains at rest $\left(\overrightarrow{p}_{f1} = 0\right)$ and the other ball moves away with the momentum that the cue ball had initially. After all non–head-on collisions, both balls move, and they move in directions that are perpendicular to each other.

Self-Test Opportunity 7.3

The experiment in Figure 7.10 specifies the angle between the two coins after the collision, but not the individual deflection angles. In order to obtain these individual angles, you also have to know how far off center on each object is the point of impact, called the *impact parameter.* Quantitatively, the impact parameter, *b,* is the distance that the original trajectory would need to be moved parallel to itself for a head-on collision (see the figure). Can you produce a sketch of the dependence of the deflection angle on the impact parameter? (*Hint:* You can do this experimentally, as shown in Figure 7.10, or you can think about limiting cases first and then try to interpolate between them.)



Self-Test Opportunity 7.4

Suppose we do exactly the same experiment as shown in Figure 7.10, but replace one of the nickels with a less heavy dime or a heavier quarter. What changes? (*Hint:* Again, you can explore the answer by doing the experiment.)

You can do a simple experiment to see if the 90° angle between final velocity vectors works out quantitatively. Put two identical coins on a piece of paper, as shown in Figure 7.10. Mark the position of one of them (the target coin) on the paper by drawing a circle around it. Then flick the other coin with your finger into the target coin (Figure 7.10a). The coins will bounce off each other and slide briefly, before friction forces bring them to rest (Figure 7.10b). Then draw a line from the final position of the target coin back to the circle that you drew, as shown in Figure 7.10c, and thereby deduce the trajectory of the other coin. The images of parts (a) and (b) are superimposed on that in part (c) of the figure to show the

motion of the coins before and after the collision, indicated by the red arrows. Measuring the angle between the two black lines in Figure 7.10c results in $\theta = 80°$, so the theoretically derived result of $\theta = 90°$ is not quite correct for this experiment. Why?

FIGURE 7.10 Collision of two nickels.

W. Bauer and G. D. Westfall

What we neglected in our derivation is the fact that—for collisions between coins or billiard balls—some of each object's kinetic energy is associated with rotation and the transfer of energy due to that motion, as well as the fact that such a collision is not quite elastic. However, the 90° rule just derived is a good first approximation for two colliding coins. You can perform a similar experiment of this kind on any billiard table; you will find that the angle of motion between the two billiard balls is not quite 90°, but this approximation will give you a good idea where your cue ball will go after you hit the target ball.

SOLVED PROBLEM 7.2 Curling

The sport of curling is all about collisions. A player slides a 19.0-kg (41.9-lb) granite "stone" 35–40 m down the ice into a target area (concentric circles with cross hairs). Teams take turns sliding stones, and the stone closest to the bull's-eye in the end wins. Whenever a stone of one team is closest to the bull's-eye, the other team attempts to knock that stone out of the way, as shown in Figure 7.11.

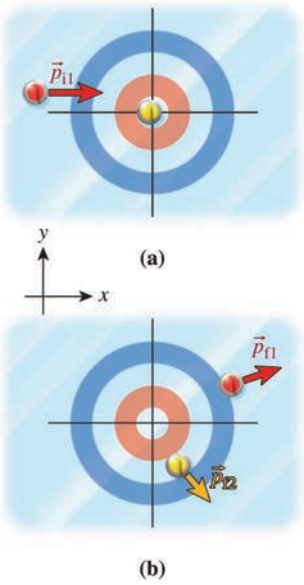


FIGURE 7.11 Overhead view of a collision of two curling stones: (a) just before the collision; (b) just after the collision.

PROBLEM

The red curling stone shown in Figure 7.11 has an initial velocity of 1.60 m/s in the x-direction and is deflected after colliding with the yellow stone to an angle of 32.0° relative to the x-axis. What are the two final momentum vectors right after this elastic collision, and what is the sum of the stones' kinetic energies?

SOLUTION

THINK

Momentum conservation tells us that the sum of the momentum vectors of both stones before the collision is equal to the sum of the momentum vectors of both stones after the collision. Energy conservation tells us that in an elastic collision, the sum of the kinetic energies of both stones before the collision is equal to the sum of the kinetic energies of both stones after the collision. Before the collision, the red stone (stone 1) has momentum and kinetic energy because it is moving, while the yellow stone (stone 2) is at rest and has no

momentum or kinetic energy. After the collision, both stones have momentum and kinetic energy. We must calculate the momentum in terms of x- and y-components.

SKETCH

A sketch of the momentum vectors of the two stones before and after the collision is shown in Figure 7.12a. The x- and y-components of the momentum vectors after the collision of the two stones are shown in Figure 7.12b.

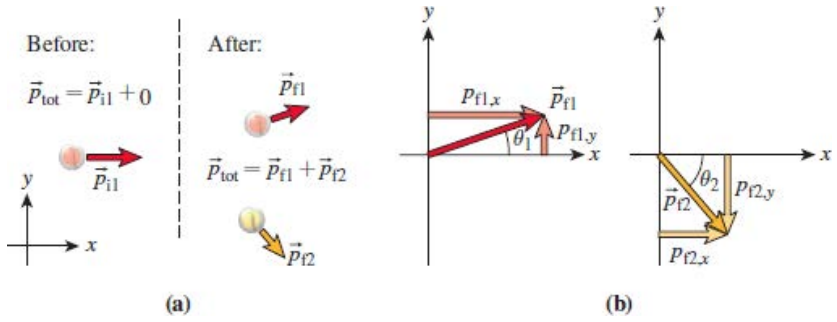

FIGURE 7.12 (a) Sketch of momentum vectors before and after the two stones collide. (b) The x- and y-components of the momentum vectors of the two stones after the collision.

RESEARCH

Momentum conservation dictates that the sum of the momenta of the two stones before the collision must equal the sum of the momenta of the two stones after the collision. We know the momenta of both stones before the collision, and our task is to calculate their momenta after the collision, based on the given directions of those momenta. For the x-components, we can write

$$p_{il,x} + 0 = p_{f1,x} + p_{f2,x}.$$

For the y-components, we can write

$$0 + 0 = p_{f1,y} + p_{f2,y}.$$

The problem specifies that stone 1 is deflected at $\theta_1 = 32.0^\circ$. According to the 90°-rule that we derived for perfectly elastic collisions between equal masses, stone 2 has to be deflected at $\theta_2 = -58.0^\circ$. Therefore, in the x-direction we obtain

$$p_{i1,x} = p_{f1,x} + p_{f2,x} = p_{f1}\ cos\theta_1\ + p_{f2}\ cos\theta_2. \qquad \text{(i)}$$

And in the y-direction, we have

$$0 = p_{\mathrm{f1,y}} + p_{\mathrm{f2},y} = p_{\mathrm{f1}} \ \sin\theta_1 \ + p_{\mathrm{f2}} \ \sin\theta_2. \qquad \text{(ii)}$$

Because we know the two angles and the initial momentum of stone 1, we need to solve a system of two equations for two unknown quantities, which are the magnitudes of the final momenta, P_{f1} and P_{f2}.

SIMPLIFY

We solve this system of equations by direct substitution. We can solve the y-component equation (ii) for pf1

$$p_{\mathrm{f1}} = -p_{\mathrm{f2}} \frac{\sin\theta_2}{\sin\theta_1} \qquad \text{(iii)}$$

and substitute into the x-component equation (i) to get

$$p_{\mathrm{i1,x}} = \left(-p_{\mathrm{f2}} \frac{\sin\theta_2}{\sin\theta_1}\right) \cos\theta_1 + p_{f2} \ \cos\theta_2.$$

We can rearrange this equation to get

$$p_{\mathrm{f2}} = \frac{p_{\mathrm{i1,x}}}{\cos\theta_2 - \sin\theta_2 \ \cot\theta_1}.$$

CALCULATE

First, we calculate the magnitude of the initial momentum of stone 1:

$$p_{\mathrm{i1,x}} = mv_{\mathrm{il,x}} = (19.0 \text{ kg})(1.60 \text{ m/s}) = 30.4 \text{ kg m/s}.$$

We can then calculate the magnitude of the final momentum of stone 2:

$$p_{\mathrm{f2}} = \frac{30.4 \text{ kg m/s}}{(\cos -58.0^\circ) - (\sin -58.0^\circ)(\cot 32.0^\circ)} = 16.10954563 \text{ kg m/s}.$$

The magnitude of the final momentum of stone 1 is

$$p_{\mathrm{f1}} = -p_{\mathrm{f2}} \frac{\sin(-58.0^\circ)}{\sin(32.0^\circ)} = 25.78066212 \text{ kg m/s}.$$

Now we can answer the question concerning the sum of the kinetic energies of the two stones after the collision. Because this collision is elastic, we can

simply calculate the initial kinetic energy of the red stone (the yellow one was at rest). Thus, our answer is

$$K = \frac{p_{1l}^2}{2m} = \frac{(30.4 \text{ kg m/s})^2}{2(19.0 \text{ kg})} = 24.32 \text{ J}.$$

ROUND

Because all the numerical values were specified to three significant figures, we report the magnitude of the final momentum of the first stone as

$$p_{f1} = 25.8 \text{ kg m/s}.$$

The direction of the first stone is $+32.0^\circ$ with respect to the horizontal. We report the magnitude of the final momentum of the second stone as

$$p_{f2} = 16.1 \text{ kg m/s}.$$

The direction of the second stone is -58.0° with respect to the horizontal.

The total kinetic energy of the two stones after the collision is

$$K = 24.3 \text{ J}.$$

Self-Test Opportunity 7.5

Double-check the results for the final momenta of the two stones in Solved Problem 7.2 by calculating the individual kinetic energies of the two stones after the collision to verify that their sum is indeed equal to the initial kinetic energy.

7.6 Totally Inelastic Collisions

In all collisions that are not completely elastic, the conservation of kinetic energy no longer holds. These collisions are called *inelastic,* because some of the initial kinetic energy gets converted into internal energy of excitation, deformation, vibration, or (eventually) heat. At first sight, this conversion of energy may make the task of calculating the final momentum or velocity vectors of the colliding objects appear more complicated. However, that is not the case; in particular, the algebra becomes considerably easier for the limiting case of totally inelastic collisions.

A totally inelastic collision is one in which the colliding objects stick to each other after colliding. This result implies that both objects have the same velocity vector after the collision: $\vec{v}_{f1} = \vec{v}_{f2} = \vec{v}_f$. (Thus, the *relative velocity* between the two colliding objects is zero after the collision.) Using $\vec{p} = m\vec{v}$ and conservation of momentum, we get the final velocity vector:

$$\vec{v}_f = \frac{m_1\vec{v}_{i1} + m_2\vec{v}_{i2}}{m_1 + m_2}. \qquad \textbf{(7.21)}$$

This useful formula enables you to solve practically all problems involving totally inelastic collisions. Derivation 7.3 shows how it was obtained.

DERIVATION 7.3

We start with the conservation law for total momentum (equation 7.8):

$$\vec{p}_{f1} + \vec{p}_{f2} = \vec{p}_{i1} + \vec{p}_{i2}$$

Now we use $\vec{p} = m\vec{v}$ and get

$$m_1\vec{v}_{f1} + m_2\vec{v}_{f2} = m_1\vec{v}_{i1} + m_2\vec{v}_{i2}$$

The condition that the collision is totally inelastic implies that the final velocities of the two objects are the same. Thus, we have equation 7.21:

$$\begin{aligned} m_1\vec{v}_f + m_2\vec{v}_f &= m_1\vec{v}_{i1} + m_2\vec{v}_{i2} \\ (m_1 + m_2)\vec{v}_f &= m_1\vec{v}_{i1} + m_2\vec{v}_{i2} \\ \vec{v}_f &= \frac{m_1\vec{v}_{i1} + m_2\vec{v}_{i2}}{m_1 + m_2}. \end{aligned}$$

Concept Check 7.9

In a totally inelastic collision between a moving object and a stationary object, the two objects will

a) stick together.

b) bounce off each other, losing energy.

c) bounce off each other, without losing energy.

Note that the condition of a totally inelastic collision implies only that the final velocities are the same for both objects. In general, the final momentum vectors of the objects can have quite different magnitudes.

We know from Newton's Third Law (see Chapter 4) that the forces two objects exert on each other during a collision are equal in magnitude. However, the changes in velocity—that is, the accelerations that the two objects experience in a totally inelastic collision—can be drastically different. The following example illustrates this phenomenon.

Concept Check 7.10

In a totally inelastic collision between a heavy car and a light car colliding head-on such as the collision discussed in Example 7.3, the force on the light car is

a) smaller than the force on the heavy car.

b) larger than the force on the heavy car.

c) zero because the cars stick together.

d) None of the above.

EXAMPLE 7.3 Head-on Collision

Consider a head-on collision of a full-size SUV, with mass M = 3023 kg, and a compact car, with mass m = 1184 kg. Each vehicle has an initial speed of v = 22.35 m/s (50 mph), and they are moving in opposite directions (Figure 7.13). So, as shown in the figure, we can say v_x is the initial velocity of the compact car and $-v_x$ is the initial velocity of the SUV. The two cars crash into each other and become entangled, a case of a totally inelastic collision.

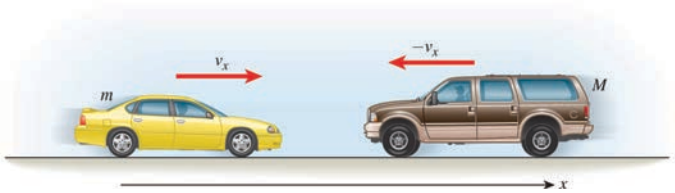

FIGURE 7.13 Head-on collision of two vehicles with different masses and identical speeds.

PROBLEM

What are the changes of the two cars' velocities in the collision? (Neglect friction between the tires and the road.)

SOLUTION

We first calculate the final velocity that the combined mass has immediately after the collision. To do this calculation, we simply use equation 7.21 and get

$$v_{f,x} = \frac{mv_x - mv_x}{m + M} = \left(\frac{m - M}{m + M}\right)v_x$$
$$= \frac{1184\ \text{kg} - 3023\ \text{kg}}{1184\ \text{kg} + 3023\ \text{kg}}(22.35\ \text{m/s}) = -9.77\ \text{m/s}$$

Thus, the velocity change for the SUV turns out to be

$$\Delta v_{\text{suv},x} = -9.77\ \text{m/s} - (-22.35\ \text{m/s}) = 12.58\ \text{m/s}.$$

However, the velocity change for the compact car is

$$\Delta v_{\text{compact},x} = -9.77\ \text{m/s} - (22.35\ \text{m/s}) = -32.12\ \text{m/s}$$

We obtain the corresponding average accelerations by dividing the velocity changes by the time interval, Δt, during which the collision takes place. This time interval is obviously the same for both cars, which means that the magnitude of the acceleration experienced by the body of the driver of the

compact car is bigger than that experienced by the body of the driver of the SUV by a factor of 32.12/12.58 = 2.55.

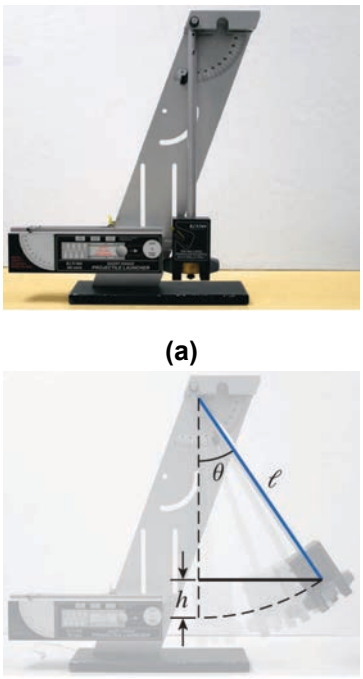
From this result alone, it is clear that it is safer to be in the SUV in this head-on collision than in the compact car. Keep in mind that this result is true even though Newton's Third Law says that the forces exerted by the two vehicles on each other are the same (compare Example 4.5).

Self-Test Opportunity 7.6

In Example 7.3, what is the ratio of the accelerations of the two cars? (*Hint:* Start with Newton's Third Law and make use of the fact that the forces the two cars exert on each other are equal.)

Ballistic Pendulum

A **ballistic pendulum** is a device that can be used to measure muzzle speeds of projectiles shot from firearms. It consists of a block of material into which the bullet is fired. This block is suspended so that it forms a pendulum (Figure 7.14). From the deflection angle of the pendulum and the known masses of the bullet, *m,* and the block, *M,* we can calculate the speed of the bullet right before it hits the block.



(a)

(b)

FIGURE 7.14 Ballistic pendulum used in an introductory physics laboratory.

a-b: W. Bauer and G. D. Westfall

To obtain an expression for the speed of the bullet in terms of the deflection angle, we have to calculate the speed of the block-plus-bullet combination right after the bullet is embedded in the block. This collision is a prototypical totally inelastic collision, and thus we can apply equation 7.21. Because the pendulum is at rest before the bullet hits it, the speed of the block-plus-bullet combination is

$$v = \frac{m}{m+M} v_b,$$

where v_b is the speed of the bullet before it hits the block and v is the speed of the combined masses right after impact. The kinetic energy of the bullet is $K_\mathrm{b} = \frac{1}{2} m v_\mathrm{b}^2$ just before it hits the block, whereas right after the collision, the block-plus-bullet combination has the kinetic energy

$$K = \tfrac{1}{2}(m+M)v^2 = \tfrac{1}{2}(m+M)\left(\frac{m}{m+M}v_b\right)^2 = \tfrac{1}{2}mv_b^2\frac{m}{m+M} = \frac{m}{m+M}$$

Clearly, kinetic energy is not conserved in the process whereby the bullet embeds in the block. (With a real ballistic pendulum, the kinetic energy is transferred into deformation of bullet and block. In this demonstration version, kinetic energy is transferred into frictional work between the bullet and the block.) Equation 7.22 shows that the total kinetic energy (and with it the total mechanical energy) is reduced by a factor of $m/(m + M)$. However, after the collision, the block-plus-bullet combination retains its remaining total energy in the ensuing pendulum motion, converting all of the initial kinetic energy of equation 7.22 into potential energy at the highest point:

$$U_{\max} = (m+M)gh = K = \tfrac{1}{2}\left(\frac{m^2}{m+M}\right)v_b^2. \qquad \textbf{(7.23)}$$

As you can see from Figure 7.14b, the height h and angle θ are related via $h = \ell\,(1 - \cos\theta)$, where ℓ is the length of the pendulum. (We found the same relationship in Solved Problem 6.3.) Substituting this result into equation 7.23 yields

$$(m+M)g\ell(1-\cos\theta) = \tfrac{1}{2}\left(\frac{m^2}{m+M}\right)v_b^2 \Rightarrow$$

$$\textbf{(7.24)}$$

$$v_b = \frac{m+M}{m}\sqrt{2g\ell(1-\cos\theta)}.$$

It is clear from equation 7.24 that practically any bullet speed can be measured with a ballistic pendulum, provided the mass of the block, *M,* is chosen appropriately. For example, if you shoot a .357 Magnum caliber round (m = 0.0081 kg) into a block (M = 3.00 kg) suspended by a 1.00 m long rope, the deflection is 21.4°, and equation 7.24 lets you determine that the muzzle speed of this bullet fired from the particular gun that you used is 432 m/s (which is a typical value for this type of ammunition).

Self-Test Opportunity 7.7

If you fire a bullet with half the mass of a .357 Magnum caliber round at the same speed into the ballistic pendulum described in the text, what is the deflection angle?

Kinetic Energy Loss in Totally Inelastic Collisions

As we have just seen, total kinetic energy is not conserved in totally inelastic collisions. How much kinetic energy is lost in the general case? We can find this loss by taking the difference between the total initial kinetic energy, K_{i}, and the total final kinetic energy, K_{f}:

$$K_{\mathrm{loss}} = K_{\mathrm{i}} - K_{\mathrm{f}}.$$

Concept Check 7.11

A ballistic pendulum is used to measure the speed of a bullet shot from a gun. The mass of the bullet is 15.0 g, and the mass of the block is 20.0 kg. When the bullet strikes the block, the combined mass rises a vertical distance of 5.00 cm. If the bullet's speed is doubled and its mass halved, the combined mass will rise

a) 2.50cm.

b) slightly less than 5 cm.

c) 5.00 cm.

d) slightly higher than 5 cm.

e) 10.00 cm.

The total initial kinetic energy is the sum of the individual kinetic energies of the two objects before the collision:

$$K_{\mathrm{i}} = \frac{P_{\mathrm{i}1}^2}{2m_1} + \frac{P_{\mathrm{i}2}^2}{2m_2}.$$

Concept Check 7.12

Suppose mass 1 is initially at rest and mass 2 moves initially with speed $v_{\mathrm{i},2}$. In a totally inelastic collision between the two objects, the loss of kinetic energy in terms of the initial kinetic energy is largest when

a) $m_1 \ll m_2$. c) $m_1 = m_2$.

b) $m_1 \gg m_2$.

The total final kinetic energy for the case in which the two objects stick together and move as one, with the total mass of $m_1 + m_2$ and velocity $\vec{v}_{\mathrm{f}}$ using equation

7.21 is

$$\begin{aligned} K_f &= \frac{1}{2}(m_1 + m_2)v_f^2 \\ &= \frac{1}{2}(m_1 + m_2)\left(\frac{m_1\vec{v}_{i1} + m_2\vec{v}_{i2}}{m_1 + m_2}\right)^2 \\ &= \frac{\left(m_1\vec{v}_{i1} + m_2\vec{v}_{i2}\right)^2}{2(m_1 + m_2)}. \end{aligned}$$

Now we can take the difference between the final and initial kinetic energies and obtain the kinetic energy loss:

$$K_{\text{loss}} = K_{\text{i}} - K_{\text{f}} = \frac{1}{2}\frac{m_1 m_2}{m_1 + m_2}\left(\vec{v}_{i1} - \vec{v}_{i2}\right)^2. \qquad \textbf{(7.25)}$$

The derivation of this result involves a bit of algebra and is omitted here. What matters, though, is that the difference in the initial velocities—that is, the initial relative velocity—enters into the equation for energy loss. We will explore the significance of this fact in the following section and again in Chapter 8, when we consider center-of-mass motion.

SOLVED PROBLEM 7.3 Forensic Science

Figure 7.15a shows a sketch of a traffic accident. The white pickup truck (car 1) with mass $m_1 = 2209\,\text{kg}$ was traveling north and hit the westbound red car (car 2) with mass $m_2 = 1474\,\text{kg}$. When the two vehicles collided, they became entangled (stuck together). Skid marks on the road reveal the exact location of the collision, and the direction in which the two vehicles were sliding immediately afterward. This direction was measured to be 38° relative to the initial direction of the white pickup truck. The white pickup truck had the right of way, because the red car had a stop sign. The driver of the red car, however, claimed that the driver of the white pickup truck was moving at a speed of at least 50. mph (22 m/s), although the speed limit was 25 mph (11 m/s). Furthermore, the driver of the red car claimed that he had stopped at the stop sign and was then driving through the intersection at a speed of less than 25 mph when the white pickup truck hit him. If the driver of the white pickup truck was speeding, he would legally forfeit the right of way and be declared responsible for the accident.

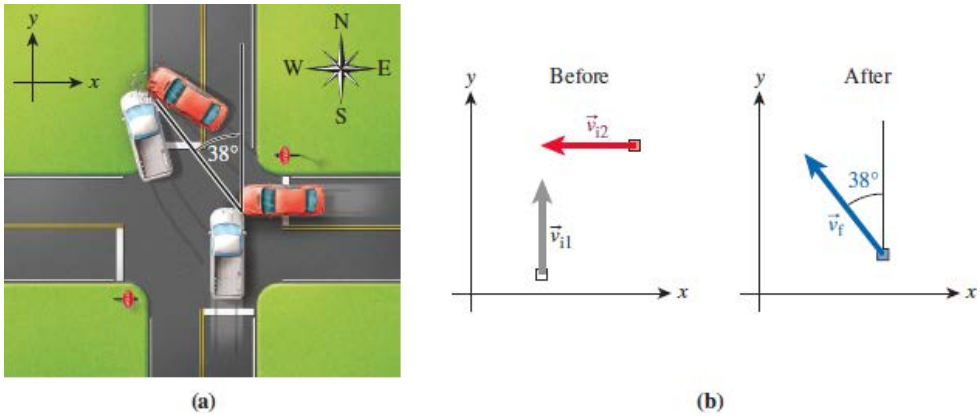


FIGURE 7.15 (a) Sketch of the accident scene. (b) Velocity vectors of the two cars before and after the collision.

PROBLEM

Can the version of the accident as described by the driver of the red car be correct?

SOLUTION

THINK

This collision is clearly a totally inelastic collision, and so we know that the velocity of the entangled cars after the collision is given by equation 7.21. We are given the angles of the initial velocities of both cars and the angle of the final velocity vector of the entangled cars. However, we are not given the

magnitudes of these three velocities. Thus, we have one equation and three unknowns. However, to solve this problem, we only need to determine the ratio of the magnitude of the initial velocity of car 1 to the magnitude of the initial velocity of car 2. Here the initial velocity is the velocity of the car just before the collision occurred.

SKETCH

A sketch of the velocity vectors of the two cars before and after the collision is shown in Figure 7.15b. A sketch of the components of the velocity vector of the two stuck together after the collision is shown in Figure 7.16.

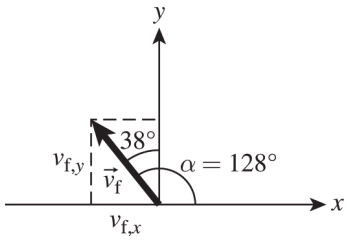

FIGURE 7.16
Components of the velocity vector of the two entangled cars after the collision.

RESEARCH

Using the coordinate system shown in Figure 7.15a, the white pickup truck (car 1) has only a y-component for its velocity vector, $\vec{v}_{i1} = v_{i1}\hat{y}$ where v_{i1} is the initial speed of the white pickup. The red car (car 2) has a velocity component only in the negative x-direction, $\vec{v}_{i2} = -v_{i2}\hat{x}$ The final velocity $\vec{v}_f$ of the cars when stuck together after the collision, expressed in terms of the initial velocities, is given by

$$\vec{v}_f = \frac{m_1\vec{v}_{i1} + m_2\vec{v}_{i2}}{m_1 + m_2}.$$

SIMPLIFY

Substituting the initial velocities into this equation for the final velocity gives

$$\vec{v}_f = v_{f,x}\hat{x} + v_{f,y}\hat{y} = \frac{-m_2 v_{i2}}{m_1 + m_2}\hat{x} + \frac{m_1 v_{i1}}{m_1 + m_2}\hat{y}.$$

The components of the final velocity vector, $v_{f,x}$ and $v_{f,y}$, are shown in Figure 7.16. From trigonometry, we obtain an expression for the tangent of the angle of the final velocity as the ratio of its y- and x-components:

$$\tan\alpha = \frac{v_{f,y}}{v_{f,x}} = \frac{\dfrac{m_1 v_{i1}}{m_1 + m_2}}{\dfrac{-m_2 v_{i2}}{m_1 + m_2}} = -\frac{m_1 v_{i1}}{m_2 v_{i2}}.$$

Thus, we can find the initial speed of car 1 in terms of the initial speed of car 2:

$$v_{i1} = -\frac{m_2 \tan\alpha}{m_1} v_{i2}.$$

We have to be careful with the value of the angle α. It is *not* 38°, as you might conclude from a casual examination of Figure 7.15b. Instead, it is 38° + 90° =128°, as shown in Figure 7.16, because angles must be measured relative to the positive *x*-axis when using the tangent formula, $\tan\alpha = v_{f,y}/v_{f,x}$.

CALCULATE

With this result and the known values of the masses of the two cars, we find

$$v_{i1} = -\frac{(1474\ \text{kg})(\tan 128^\circ)}{2209\ \text{kg}} v_{i2} = 0.854066983 v_{i2}$$

ROUND

The angle at which the two cars moved after the collision was specified to two significant digits, so we report our answer to two significant digits:

$$v_{i1} = 0.85 v_{i2}.$$

The white pickup truck (car 1) was moving at a slower speed than the red car (car 2). The story of the driver of the red car is not consistent with the facts. Apparently, the driver of the white pickup truck was not speeding at the time of the collision, and the cause of the accident was the driver of the red car running the stop sign.

Self-Test Opportunity 7.8

To double-check the result for Solved Problem 7.3, estimate what the angle of deflection would have been if the white pickup truck had been traveling with a speed of 50. mph and the red car had been traveling with a speed of 25 mph just before the collision.

Explosions

In totally inelastic collisions, two or more objects merge into one and move in unison with the same total momentum after the collision as before it. The reverse process is also possible. If an object moves with initial momentum $\overrightarrow{p_{\mathrm{i}}}$ and then explodes into fragments, the process of the explosion only generates internal forces among the fragments. Because an explosion takes place over a very short time, the impulse due to external forces can usually be neglected. In such a situation, according to Newton's Third Law, the total momentum is conserved. This result implies that the sum of the momentum vectors of the fragments has to add up to the initial momentum vector of the object:

$$\overrightarrow{p_{\mathrm{i}}} = \sum_{k=1}^{n} \overrightarrow{p_{\mathrm{fk}}}. \tag{7.26}$$

This equation relating the momentum of the exploding object just before the explosion to the sum of the momentum vectors of the fragments after the explosion is exactly the same as the equation for a totally inelastic collision except that the indices for the initial and final states are exchanged. In particular, if an object breaks up into two fragments, equation 7.26 matches equation 7.21, with the indices i and f exchanged:

$$\overrightarrow{v_{\mathrm{i}}} = \frac{m_1\overrightarrow{v_{\mathrm{f1}}} + m_2\overrightarrow{v_{\mathrm{f2}}}}{m_1 + m_2}. \tag{7.27}$$

This relationship allows us, for example, to reconstruct the initial velocity if we know the fragments' velocities and masses. Further, we can calculate the energy released in a breakup that yields two fragments from equation 7.25, again with the indices i and f exchanged:

$$K_{\mathrm{release}} = K_{\mathrm{f}} - K_{\mathrm{i}} = \frac{1}{2}\frac{m_1 m_2}{2m_1 + m_2}\left(\overrightarrow{v_{\mathrm{f1}}} - \overrightarrow{v_{\mathrm{f2}}}\right)^2. \tag{7.28}$$

EXAMPLE 7.4 Decay of a Radon Nucleus

Radon is a gas that is produced by the radioactive decay of naturally occurring heavy nuclei, such as thorium and uranium. Radon gas can be breathed into the lungs, where it can decay further. The nucleus of a radon atom has a mass of 222 u, where u is an atomic mass unit (to be introduced in Chapter 40). Assume that the nucleus is at rest when it decays into a polonium nucleus with mass 218 u and a helium nucleus with mass 4 u (called an *alpha particle*), releasing 5.59 MeV of energy.

PROBLEM

What are the kinetic energies of the polonium nucleus and the alpha particle?

SOLUTION

The polonium nucleus and the alpha particle are emitted in opposite directions. We will say that the alpha particle is emitted with speed v_{x1} in the positive x-direction and the polonium nucleus is emitted with speed v_{x2} in the negative x-direction. The mass of the alpha particle is $m_1 = 4$ u, and the mass of the polonium nucleus is $m_2 = 218$ u. The initial velocity of the radon nucleus is zero, so we can use equation 7.27 to write

$$\vec{v}_{\mathrm{i}} = 0 = \frac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2},$$

which gives us

$$m_1 v_{x1} = -m_2 v_{x2}. \qquad \text{(i)}$$

Using equation 7.28, we can express the kinetic energy released by the decay of the radon nucleus

$$K_{\mathrm{release}} = \frac{1}{2}\frac{m_1 m_2}{m_1 + m_2}(v_{x1} - v_{x2})^2. \qquad \text{(ii)}$$

We can then use equation (i) to express the velocity of the polonium nucleus in terms of the velocity of the alpha particle:

$$v_{x2} = \frac{m_1}{m_2} v_{x1}.$$

Substituting from equation (i) into equation (ii) gives us

$$K_{\text{release}} = \frac{1}{2}\frac{m_1 m_2}{m_1+m_2}\left(v_{x1} + \frac{m_1}{m_2}v_{x1}\right)^2 = \frac{1}{2}\frac{m_1 m_2 v_{\text{x1}}^2}{m_1+m_2}\left(\frac{m_1+m_2}{m_2}\right)^2 .($$

Rearranging equation (iii) leads to

$$K_{\text{release}} = \frac{1}{2}\frac{m_1(m_1+m_2)v_{\text{x1}}^2}{m_2} = \frac{1}{2}m_1 v_{\text{x1}}^2 \frac{m_1+m_2}{m_2} = K_1\left(\frac{m_1+m_2}{m_2}\right)$$

where K_1 is the kinetic energy of the alpha particle. This kinetic energy is then

$$K_1 = K_{\text{release}}\left(\frac{m_2}{m_1+m_2}\right).$$

Putting in the numerical values, we get the kinetic energy of the alpha particle:

$$K_1 = (5.59\,\text{MeV})\left(\frac{218}{4+218}\right) = 5.49\,\text{MeV}\,.$$

The kinetic energy, K_2, of the polonium nucleus is then

$$K_2 = K_{\text{release}} - K_1 = 5.59\text{MeV} - 5.49\text{MeV} = 0.10\,\text{MeV}\,.$$

The alpha particle gets most of the kinetic energy when the radon nucleus decays, and this is sufficient energy to damage surrounding tissue in the lungs.

EXAMPLE 7.5 Particle Physics

The conservation laws of momentum and energy are essential for analyzing the products of particle collisions at high energies, such as those produced at Fermilab's Tevatron, near Chicago, Illinois, which was the world's highest-energy proton-antiproton accelerator. (An accelerator called LHC, for Large Hadron Collider, began operation in 2008 at the CERN Laboratory in Geneva, Switzerland, and it is more powerful than Tevatron. However, the LHC is a proton-proton accelerator.)

In the Tevatron accelerator, particle physicists collide protons and antiprotons at total energies of 1.96 TeV (hence the name). Remember that $1\text{eV} = 1.602 \cdot 10^{-19}\,\text{J}$; so $1.96\text{TeV} = 1.96 \cdot 10^{12}\text{eV} = 3.1 \cdot 10^{-7}\,\text{J}$. The Tevatron is set up so that the protons and antiprotons move in the collider ring in opposite directions, with, for all practical purposes, exactly opposite momentum vectors. The main particle detectors, D-Zero and CDF, are located at the interaction regions, where protons and antiprotons collide.

Figure 7.17a shows an example of such a collision. In this computer-generated display of one particular collision event at the D-Zero detector, the proton's initial momentum vector points straight into the page and that of the antiproton points straight out of the page. Thus, the total initial momentum of the proton-antiproton system is zero. The explosion produced by this collision produces several fragments, almost all of which are registered by the detector. These measurements are indicated in the display (Figure 7.17a). Superimposed on this event display are the momentum vectors of the corresponding parent particles of these fragments, with their lengths and directions based on computer analysis of the detector response. (The momentum unit GeV/c, commonly used in high-energy physics and shown in the figure, is the energy unit GeV divided by the speed of light.) In Figure 7.17b, the momentum vectors have been summed graphically, giving a nonzero vector, indicated by the thicker green arrow.

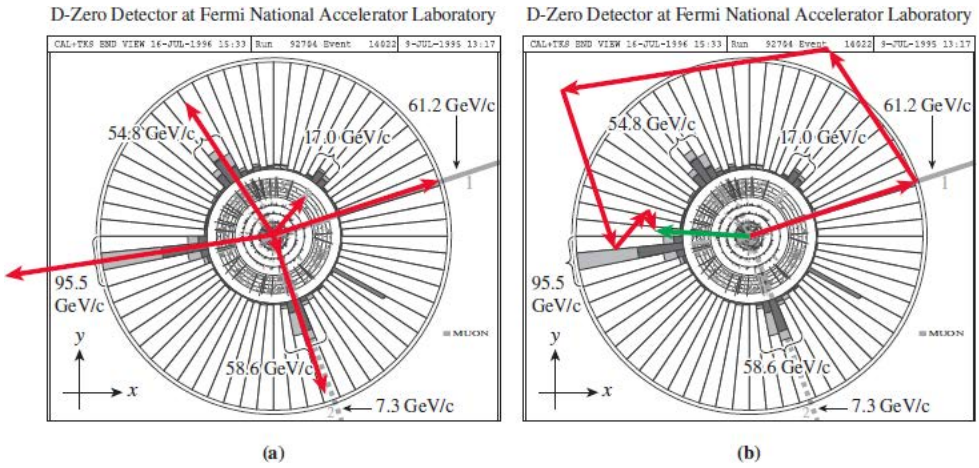

FIGURE 7.17 Event display generated by the D-Zero collaboration and education office at Fermilab, showing a top-quark event. (a) Momentum vectors of the detected particles produced by the event; (b) graphical addition of the momentum vectors, showing that they add up to a nonzero sum, indicated by the thicker green arrow.

However, conservation of momentum absolutely requires that the sum of the momentum vectors of all particles produced in this collision must be zero. Thus, conservation of momentum allows us to assign the missing momentum represented by the green arrow to a particle that escaped undetected. With the aid of this missing-momentum analysis, physicists at Fermilab were able to show that the event displayed here was one in which an elusive particle known as a *top quark* was produced.

Self-Test Opportunity 7.9

The length of each vector arrow in Figure 7.17b is proportional to the magnitude of the momentum vector of the particular particle. Can you determine the momentum of the nondetected particle (green arrow)?

SOLVED PROBLEM 7.4 Collision with a Parked Car

PROBLEM

A moving truck strikes a car parked in the breakdown lane of a highway. During the collision, the vehicles stick together and slide to a stop. The moving truck has a total mass of 1982 kg (including the driver), and the parked car has a total mass of 966 kg. If the vehicles slide 10.5 m before coming to rest, how fast was the truck going? The coefficient of kinetic friction between the tires and the road is 0.350.

SOLUTION

THINK

This situation is a totally inelastic collision of a moving truck with a parked car. The kinetic energy of the truck/car combination after the collision is reduced by the energy dissipated by friction while the truck/car combination is sliding. The kinetic energy of the truck/car combination can be related to the initial speed of the truck before the collision.

SKETCH

Figure 7.18 is a sketch of the moving truck, m_1, and the parked car, m_2. Before the collision, the truck is moving with an initial speed of $v_{i1,x}$. After the truck collides with the car, the two vehicles slide together with a speed of $v_{f,x}$.

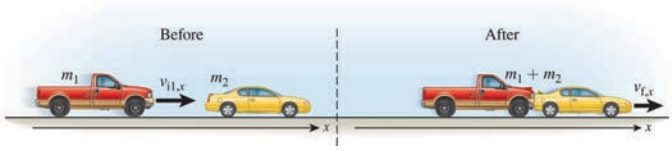

FIGURE 7.18 The collision between a moving truck and a parked car.

SKETCH

Momentum conservation tells us that the velocity of the two vehicles just after the totally inelastic collision is given by

$$v_{f,x} = \frac{m_1 v_{i1,x}}{m_1 + m_2}.$$

The kinetic energy of the combined truck/car combination just after the collision is

$$K = \frac{1}{2}(m_1 + m_2)v_{f,x,}^2 \qquad \text{(i)}$$

where, as usual, $v_{\mathrm{f,x}}$ is the final speed.

We finish solving this problem by using the work-energy theorem from Chapter 6, $W_{\mathrm{f}} = \Delta K + \Delta U$. In this situation, the energy dissipated by friction, W_{f}, on the truck/car system is equal to the change in kinetic energy, ΔK, of the truck/car system, since $\Delta U = 0$. We can thus write

$$W_{\mathrm{f}} = \Delta K.$$

The change in kinetic energy is equal to zero (since the truck and car finally stop) minus the kinetic energy of the truck/car system just after the collision. The truck/car system slides a

distance d. The x-component of the frictional force slowing down the truck/car system is given by $f_x = -\mu_{\mathrm{k}} N$, where μ_{k} is the coefficient of kinetic friction and N is the magnitude of the normal force. The normal force has a magnitude equal to the weight of the truck/car system, or $N = (m_1 + m_2)g$. The energy dissipated is equal to the x-component of the friction force times the distance that the truck/car system slides along the x-axis, so we can write

$$W_{\mathrm{f}} = f_x d = -\mu_k (m_1 + m_2) g d. \qquad \text{(ii)}$$

SIMPLIFY

We can substitute for the final speed in equation (i) for the kinetic energy and obtain

$$K = \tfrac{1}{2}(m_1 + m_2) v_{\mathrm{f,x}}^2 = \tfrac{1}{2}(m_1 + m_2)\left(\frac{m_1 v_{\mathrm{i1},x}}{m_1 + m_2}\right)^2 = \frac{(m_1 v_{\mathrm{i1},x})^2}{2(m_1 + m_2)}.$$

Combining this equation with the work-energy theorem and equation (ii) for the energy dissipated by friction, we get

$$\Delta K = W_{\mathrm{f}} = 0 - \frac{(m_1 v_{\mathrm{i1,x}})^2}{2(m_1 + m_2)} = -\mu_k (m_1 + m_2) g d.$$

Solving for $v_{\mathrm{i1,x}}$ finally leads us to

$$v_{\mathrm{i1,x}} = \frac{(m_1 + m_2)}{m_1}\sqrt{2\mu_k g d}.$$

CALCULATE

Putting in the numerical values results in

$$v_{\mathrm{i1,x}} = \frac{1982\ \mathrm{kg} + 966\ \ \mathrm{kg}}{1982\ \ \mathrm{kg}} \sqrt{2(0.350)(9.81\mathrm{m/s^2})(10.5\mathrm{m})} = 12.62996079$$

ROUND

All of the numerical values given in this problem were specified to at least three significant figures. Therefore, we report our result as

$$v_{\mathrm{i1,x}} = 12.6\mathrm{m/s}.$$

DOUBLE-CHECK

The initial speed of the truck was 12.6 m/s (28.2 mph), which is within the range of normal speeds for vehicles on highways and thus certainly within the expected magnitude for our result.

7.7 Partially Inelastic Collisions

What happens if a collision is neither elastic nor totally inelastic? Most real collisions are somewhere between these two extremes, as we saw in the coin collision experiment in Figure 7.10. Therefore, it is important to look at partially inelastic collisions in more detail.

We have already seen that the relative velocity of the two objects in a one-dimensional elastic collision simply changes sign. The relative velocity becomes zero in totally inelastic collisions. Thus, it seems logical to define the elasticity of a collision in a way that involves the ratio of initial and final relative velocities.

The **coefficient of restitution**, symbolized by ϵ, is the ratio of the magnitudes of the final and initial relative velocities in a collision:

$$\epsilon = \frac{\left|\vec{v}_{\mathrm{f1}} - \vec{v}_{\mathrm{f2}}\right|}{\left|\vec{v}_{\mathrm{i1}} - \vec{v}_{\mathrm{i2}}\right|}. \qquad \textbf{(7.29)}$$

This definition gives a coefficient of restitution of $\epsilon = 1$ for elastic collisions and $\epsilon = 0$ for totally inelastic collisions.

First, let's examine what happens in the limit where one of the two colliding objects is the ground (for all intents and purposes, infinitely massive) and the other one is a ball. We can see from equation 7.29 that if the ground does not move when the ball bounces, $\vec{v}_{\mathrm{i1}} = \vec{v}_{\mathrm{f1}} = 0$, and we can write for the speed of the ball:

$$v_{\mathrm{f2}} = \epsilon v_{i2}.$$

If we release the ball from some height, h_{i}, we know that it reaches a speed of $v_{\mathrm{i}} = \sqrt{2gh_{\mathrm{i}}}$ immediately before it collides with the ground. If the collision is elastic, the speed of the ball just after the collision is the same, $v_{\mathrm{f}} = v_{\mathrm{i}} = \sqrt{2gh_{\mathrm{i}}}$ and it bounces back to the same height from which it was released. If the collision is totally inelastic, as in the case of a ball of putty that falls to the ground and then just stays there, the final speed is zero. For all cases in between, we can find the coefficient of restitution from the height h_{f} that the ball returns to:

$$h_f = \frac{v_f^2}{2g} = \frac{\in^2 v_i^2}{2g} = \in^2 h_i \Rightarrow$$
$$\in = \sqrt{h_f / h_i}.$$

Using this formula to measure the coefficient of restitution, we find ϵ = 0.58 for baseballs, using typical relative velocities that would occur in ball-bat collisions in Major League games.

Self-Test Opportunity 7.10

The maximum kinetic energy loss is obtained in the limit of a totally inelastic collision. What fraction of this maximum possible energy loss is obtained in the case where $\in = \frac{1}{2}$?

In general, we can state (without proof) that the kinetic energy loss in partially inelastic collisions is

$$K_{loss} = K_i - K_f = \frac{1}{2} \frac{m_1 m_2}{m_1 + m_2} \left(1 - \in^2\right) \left(\overrightarrow{v}_{i1} - \overrightarrow{v}_{i2}\right)^2. \qquad \textbf{(7.30)}$$

In the limit $\in \rightarrow 1$, we obtain $K_{loss} = 0$, i.e., no loss in kinetic energy, as required for elastic collisions. In addition, in the limit $\in \rightarrow 0$, equation 7.30 matches the energy release for totally inelastic collisions already shown in equation 7.28.

Partially Inelastic Collision with a Wall

If you play racquetball or squash, you know that the ball loses energy when you hit it against the wall. While the angle at which a ball bounces off the wall in an elastic collision is the same as the angle at which it hit the wall, the final angle is not so clear for a partially inelastic collision (Figure 7.19).

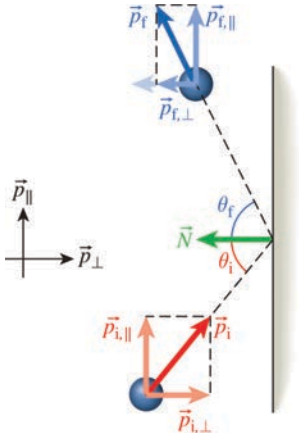

FIGURE 7.19
Partially inelastic collision of a ball with a wall.

The key to obtaining a first approximation to this angle is to consider only the normal force, which acts in a direction perpendicular to the wall. Then the momentum component directed along the wall remains unchanged, just as in an elastic collision. However, the momentum component perpendicular to the wall is not simply inverted but is also reduced in magnitude by the coefficient of restitution: $p_{f,\perp} = -\in p_{i,\perp}$ This approximation gives us an angle of reflection relative to the normal that is larger than the initial angle:

$$\theta_f = \cot^{-1}\frac{p_{f,\perp}}{p_{f,\parallel}} = \cot^{-1}\frac{\in p_{i,\perp}}{p_{i,\parallel}} > \theta_i. \qquad \textbf{(7.31)}$$

The magnitude of the final momentum vector is also changed and reduces to

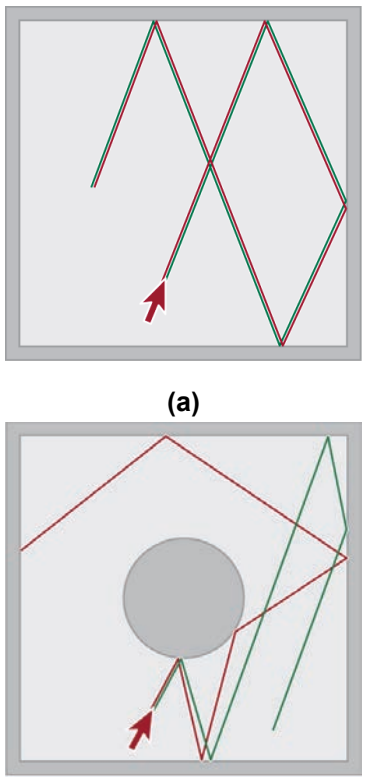
$$p_f = \sqrt{p_{f,\parallel}^2 + p_{f,\perp}^2} = \sqrt{p_{i,\parallel}^2 + \in^2 p_{i,\perp}^2} < p_i. \qquad \textbf{(7.32)}$$

If we want a more accurate description, we need to include the effect of a friction force between ball and wall, acting for the duration of the collision. (This is why squash balls and racquetballs leave marks on the walls.) Further, the collision with the wall also changes the rotation of the ball, and thus additionally alters the direction and kinetic energy of the ball as it bounces off. However, equations 7.31

and 7.32 still provide a very reasonable first approximation to partially inelastic collisions with walls.

7.8 Billiards and Chaos

Let's look at billiards in an abstract way. The abstract billiard system is a rectangular (or even square) billiard table, on which particles can bounce around and have elastic collisions with the sides. Between collisions, these particles move on straight paths without energy loss. When two particles start off close to each other, as in Figure 7.20a, they stay close to each other. The figure shows the paths (red and green lines) of two particles, which start close to each other with the same initial momentum (indicated by the red arrow) and clearly stay close.



(a)

(b)

FIGURE 7.20 Collisions of particles with walls for two particles starting out very close to each other and with the same momentum: (a) regular billiard table; (b) Sinai billiard.

The situation becomes qualitatively different when a circular wall is added in the middle of the billiard table. Now each collision with the circle drives the two paths farther apart. In Figure 7.20b, you can see that one collision with the circle was enough to separate the red and green lines for good. This type of billiard system is called a *Sinai billiard,* named after the Russian academician Yakov Sinai (b. 1935) who first studied it in 1970. The Sinai billiard exhibits **chaotic motion**, or motion that follows the laws of physics—it is not random—but cannot be predicted because it changes significantly with slight changes in conditions, including starting conditions. Surprisingly, Sinai billiard systems are still not fully explored. For example, only in the last two decades have the decay properties of these systems been described. Researchers interested in the physics of chaos are continually gaining new knowledge of these systems.

Here is one example from the authors' own research. If you block off the pockets and cut a hole into the side wall of a conventional billiard table and then measure the time it takes a ball to hit this hole and escape, you obtain a power-law decay time distribution: $N(t) = N(t = 0)t^{-1}$, where $N(t = 0)$ is the number of balls used in the experiment and $N(t)$ is the number of balls remaining after time t. However, if you did the same for the Sinai billiard, you would obtain an exponential time dependence: $N(t) = N(t = 0)e^{-t/T}$.

These types of investigations are not simply theoretical speculations. Try the following experiment: Place a billiard ball on the surface of a table and hold onto the ball. Then hold a second billiard ball as exactly as you can directly above the first one and release it from a height of a few inches (or centimeters). You will see that the upper ball cannot be made to bounce on the lower one more than three or four times before going off in some uncontrollable direction. Even if you could fix the location of the two balls to atomic precision, the upper ball would bounce off the lower one after only ten to fifteen times. This result means that the ability to predict the outcome of this experiment extends to only a few collisions. This limitation of predictability goes to the heart of chaos science. It is one of the main reasons, for example, that exact long-term weather forecasting is impossible. After all, air molecules bounce off each other, too.

Laplace's Demon

Marquis Pierre-Simon Laplace (1749–1827) was an eminent French physicist and mathematician of the 18th century. He lived during the time of the French Revolution and other major social upheavals, characterized by the struggle for self-determination and freedom. No painting symbolizes this struggle better than *Liberty Leading the People* (1830) by Eugène Delacroix (Figure 7.21).

FIGURE 7.21 *Liberty Leading the People,* Eugène Delacroix (Louvre, Paris, France).

Oleg Golovnev/Shutterstock

Laplace had an interesting idea, now known as *Laplace's Demon*. He reasoned that everything is made of atoms, and all atoms obey differential equations governed by the forces acting on them. If the initial positions and velocities of all atoms, together with all force laws, were fed into a huge computer (he called this an "intellect"), then "for such an intellect nothing could be uncertain and the future just like the past would be present before its eyes." This reasoning implies that everything is predetermined; we are only cogs in a huge clockwork, and nobody has free will. Ironically, Laplace came up with this idea at a time when quite a few people believed that they could achieve free will, if only they could overthrow those in power.

The downfall of Laplace's Demon comes from the combination of two principles of physics. One is from chaos science, which points out that long-term predictability depends sensitively on knowledge of the initial conditions, as seen in the experiment with the bouncing billiard balls. This principle applies to molecules interacting with one another, as, for example, air molecules do. The other physics principle notes the impossibility of specifying both the position and the momentum of any object exactly at the same time. This is the uncertainty relation in quantum physics (discussed in Chapter 36). Thus, free will is still alive and well, at least from the perspective of physics constraints—the predictability of large or complex systems such as the weather or the human brain over the long term is impossible. The combination of chaos theory and quantum theory ensures that Laplace's "intellect" or any computer cannot possibly calculate and predict our individual decisions.

WHAT WE HAVE LEARNED EXAM STUDY GUIDE

- Momentum is defined as the product of an object's mass and its velocity: $\vec{p} = m\vec{v}$
- Newton's Second Law can be written as $\vec{F} = d\vec{p}/dt$
- Impulse is the change in an object's momentum and is equal to the time integral of the applied external force:

$$\vec{J} = \Delta\vec{p} = \int_{t_i}^{t_f} \vec{F} dt.$$

- In a collision of two objects, momentum can be exchanged, but the sum of the momenta of the colliding objects remains constant: $\vec{p}_{f1} + \vec{p}_{f2} = \vec{p}_{i1} + \vec{p}_{i2}$. This is the law of conservation of total momentum.
- Collisions can be elastic, totally inelastic, or partially inelastic.
- In elastic collisions, the total kinetic energy also remains constant:

$$\frac{p_{f1}^2}{2m_1} + \frac{p_{f2}^2}{2m_2} = \frac{p_{i1}^2}{2m_1} + \frac{p_{i2}^2}{2m_2}.$$

- For one-dimensional elastic collisions in general, the final velocities of the two colliding objects can be expressed as functions of the initial velocities:

$$v_{f1,x} = \left(\frac{m_1 - m_2}{m_1 + m_2}\right) v_{i1,x} + \left(\frac{2m_2}{m_1 + m_2}\right) v_{i2,x}$$
$$v_{f2,x} = \left(\frac{2m_1}{m_1 + m_2}\right) v_{i1,x} + \left(\frac{m_2 - m_1}{m_1 + m_2}\right) v_{i2,x}.$$

- In totally inelastic collisions, the colliding objects stick together after the collision and have the same velocity:

$$\vec{v}_f = \left(m_1\vec{v}_{i1} + m_2\vec{v}_{i2}\right)/(m_1 + m_2).$$

- All partially inelastic collisions are characterized by a coefficient of restitution, defined as the ratio of the magnitudes of the final and the initial relative velocities: $\epsilon = \left|\vec{v}_{f1} - \vec{v}_{f2}\right| / \left|\vec{v}_{i1} - \vec{v}_{i2}\right|$. The kinetic energy loss in a partially inelastic collision is then given by

$$\Delta K = K_i - K_f \frac{1}{2} \frac{m_1 m_2}{m_1 + m_2} (1 - \epsilon^2) \left(\vec{v}_{i1} - \vec{v}_{i2}\right)^2.$$

ANSWERS TO SELF-TEST OPPORTUNITIES

7.1 Examples include: rubber door stop, padded baseball glove, padded dashboard in car, water-filled barrels in front of bridge abutments on highways, pads on basketball goal support, pads on goalpost supports on football field, portable pad for gym floor, padded shoe inserts.

7.2 The collision is that of a stationary golf ball being struck by a moving golf club head. The head of the driver has more mass than the golf ball. If we take the golf ball to be m_1 and the driver head to be m_2, then $m_2 > m_1$ and

$$v_{\text{f1,x}} = \left(\frac{2m_2}{m_1 + m_2}\right) v_{\text{i2,x.}}$$

So the speed of the golf ball after impact will be a factor of

$$\left(\frac{2m_2}{m_1 + m_2}\right) > 1$$

greater than the speed of the golf club head. If the golf club head is much more massive than the golf ball, then

$$\left(\frac{2m_2}{m_1 + m_2}\right) \approx 2.$$

7.3 Take two coins, each with radius R. Collide with impact parameter b. The angle by which the moving coin is deflected is θ.

$$b{=}0 \rightarrow \theta = 90^\circ$$
$$b{=}2R \rightarrow \theta = 0^\circ$$

The complete function is

$$\theta = \cos^{-1}\left(\frac{b}{2R}\right).$$

7.4 Suppose the larger coin is at rest and we shoot a smaller coin at the larger coin. For b = 0, we get θ = 180° and for $b = R_1 + R_2$, we get θ = 0°.

For a very small moving coin incident on a very large stationary coin with radius R, we get

$$b = R\cos\left(\theta/2\right) \Rightarrow \theta = 2\cos^{-1}\left(\frac{b}{R}\right).$$

Suppose the smaller coin is at rest and we shoot a larger coin at the smaller coin. For b = 0, we get θ = 0 because the larger coin continues forward in a head-on collision. For $b = R_1 + R_2$, we get θ = 0.

7.5 The initial kinetic energy is

$$K_{\mathrm{I}} = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(19.0\ \mathrm{kg})(1.60\ \mathrm{m/s})^2 = 24.3\,\mathrm{J}.$$

7.6 *F* = *ma,* and both experience the same force

$$\begin{aligned} m_{\mathrm{SUV}}a_{\mathrm{SUV}} &= m_{\mathrm{compact}}a_{\mathrm{compact}} \\ \frac{a_{\mathrm{compact}}}{a_{\mathrm{SUV}}} &= \frac{m_{\mathrm{SUV}}}{m_{\mathrm{compact}}} = \frac{3023\ \mathrm{kg}}{1184\ \mathrm{kg}} = 2.553. \end{aligned}$$

7.7

$$\begin{aligned} v_{\mathrm{b}} &= \frac{m+M}{m}\sqrt{2g\ell(1-\cos\theta)} \Rightarrow \\ \theta &= \cos^{-1}\left(1 - \frac{1}{2\mathrm{g}\ell}\left(\frac{mv_{\mathrm{b}}}{m+M}\right)^2\right) \\ \theta &= \cos^{-1}\left(1 - \frac{1}{2(9.81\mathrm{m/s^2})(1.00\mathrm{m})}\left(\frac{(0.004\ \mathrm{kg})(432\mathrm{m/s})}{0.004\ \mathrm{kg}\ \ 3.00\ \mathrm{kg}}\right)^2\right) \\ \theta &= 10.5^\circ \end{aligned}$$

or slightly less than half the original angle.

7.8 Again we have to be careful with the tangent. The *x*-component is negative and the *y*-component is positive. So we must end up in quadrant II with $90^\circ < \alpha < 180^\circ$.

$$\begin{aligned} \tan\alpha &= \frac{-m_1 v_{\mathrm{i}1}}{m_2 v_{\mathrm{i}2}} \\ \alpha &= \tan^{-1}\left(\frac{-m_1 v_{\mathrm{i}1}}{m_2 v_{\mathrm{i}2}}\right) = \tan^{-1}\left(\frac{-2209\ \mathrm{kg}\ \ 50\,\mathrm{mph}}{1474\ \mathrm{kg}\ \ 25\,\mathrm{mph}}\right) \end{aligned}$$

α = 108° or 18° from the vertical, compared with 38° from the vertical in the actual collision.

7.9 The length of the missing momentum vector is 1.4 cm. The length of the 95.5 GeV/*c* vector is 4.0 cm. The missing momentum is then (4.0/1.4)95.5 GeV/*c* = 33 GeV/*c*.

7.10 Loss for ∈ = 0.5 is

$$K_{\text{loss},0.5} = K_{\text{I}} - K_{\text{f}} = \frac{1}{2}\frac{m_1 m_2}{m_1 + m_2}\left(1 - (0.5)^2\right)\left(\vec{v}_{\text{i1}} - \vec{v}_{\text{i2}}\right)^2$$
$$= (0.75)\frac{1}{2}\frac{m_1 m_2}{m_1 + m_2}\left(\vec{v}_{\text{i1}} - \vec{v}_{\text{i2}}\right)^2 = 0.75\ K_{\text{loss,max}}.$$

PROBLEM-SOLVING GUIDELINES: CONSERVATION OF MOMENTUM

1. Conservation of momentum applies to isolated systems with no external forces acting on them—always be sure the problem involves a situation that satisfies or approximately satisfies these conditions. Also, be sure that you take account of every interacting part of the system; conservation of momentum applies to the entire system, not just one object.

2. If the situation you're analyzing involves a collision or explosion, identify the momenta immediately before and immediately after the event to use in the conservation of momentum equation. Remember that a change in total momentum equals an impulse, but the impulse can be either an instantaneous force acting over an instant of time or an average force acting over a time interval.

3. If the problem involves a collision, you need to recognize what kind of collision it is. If the collision is perfectly elastic, kinetic energy is conserved, but this is not true for other kinds of collisions.

4. Remember that momentum is a vector and is conserved in the *x-*, *y-*, and *z-*directions separately. For a collision in more than one dimension, you may need additional information to analyze momentum changes completely.

MULTIPLE-CHOICE QUESTIONS

7.1 In many old Western movies, a bandit is knocked back 3 m after being shot by a sheriff. Which statement best describes what happened to the sheriff after he fired his gun?

a) He remained in the same position.

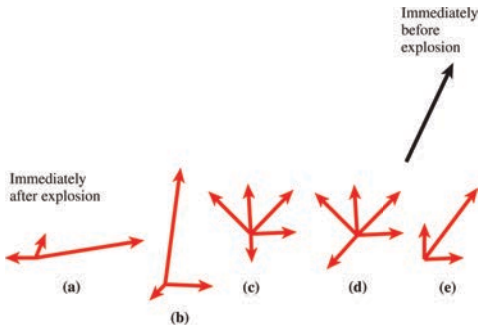
b) He was knocked back a step or two.

c) He was knocked back approximately 3 m.

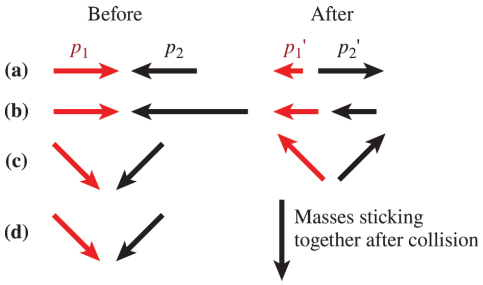
d) He was knocked forward slightly.

e) He was pushed upward.

7.2 A fireworks projectile is traveling upward as shown in the figure on the right just before it explodes. Sets of possible momentum vectors for the shell fragments immediately after the explosion are shown below. Which sets could actually occur?



7.3 The figure shows sets of possible momentum vectors before and after a collision, with no external forces acting. Which sets could actually occur?



7.4 The value of the momentum for a system is the same at a later time as at an earlier time if there are no

a) collisions between particles within the system.

b) inelastic collisions between particles within the system.

c) changes of momentum of individual particles within the system.

d) internal forces acting between particles within the system.

e) external forces acting on particles of the system.

7.5 Consider these three situations:

(i) A ball moving to the right at speed v is brought to rest.

(ii) The same ball at rest is projected at speed v toward the left.

(iii) The same ball moving to the left at speed v speeds up to $2v$.

In which situation(s) does the ball undergo the largest change in momentum?

a) situation (i)

b) situation (ii)

c) situation (iii)

d) situation (i) and (ii)

e) all three situations

7.6 Consider two carts, of masses m and $2m$, at rest on a frictionless air track. If you push the lower-mass cart for 35 cm and then the other cart for the same distance and with the same force, which cart undergoes the larger change in momentum?

a) The cart with mass m has the larger change.

b) The cart with mass $2m$ has the larger change.

c) The change in momentum is the same for both carts.

d) It is impossible to tell from the information given.

7.7 Consider two carts, of masses m and $2m$, at rest on a frictionless air track. If you push the lower-mass cart for 3 s and then the other cart for the same length of time and with the same force, which cart undergoes the larger change in momentum?

a) The cart with mass m has the larger change.

b) The cart with mass $2m$ has the larger change.

c) The change in momentum is the same for both carts.

d) It is impossible to tell from the information given.

7.8 Which of the following statements about car collisions is (are) true?

a) The essential safety benefit of crumple zones (parts of the front of a car designed to receive maximum deformation during a head-on collision) is due to their absorbing kinetic energy, converting it into deformation, and lengthening the effective collision time, thus reducing the average force experienced by the driver.

b) If car 1 has mass m and speed v, and car 2 has mass $0.5m$ and speed $1.5v$, then both cars have the same momentum.

c) If two identical cars with identical speeds collide head-on, the magnitude of the impulse received by each car and each driver is the same as if one car at the same speed had collided head-on with a concrete wall.

d) Car 1 has mass m and car 2 has mass $2m$. In a head-on collision of these cars while moving at identical speeds in opposite directions, car 1 experiences a bigger acceleration than car 2.

e) Car 1 has mass m and car 2 has mass $2m$. In a head-on collision of these cars while moving at identical speeds in opposite directions, car 1 receives an impulse of bigger magnitude than that received by car 2.

7.9 A fireworks projectile is launched upward at an angle above a large flat plane. When the projectile reaches the top of its flight, at a height of h above a point that is a horizontal distance D from where it was launched, the projectile explodes into two equal pieces. One piece reverses its velocity and travels directly back to the launch point. How far from the launch point does the other piece land?

a) D

b) $2D$

c) $3D$

d) $4D$

7.10 A red curling stone moving with a speed of 2.0 m/s collides head-on with a yellow curling stone at rest (totally elastic collision). What are the speeds of the two curling stones just after the collision?

a) The red stone is at rest, and the yellow stone is moving with a speed of 2.0 m/s.

b) The red stone and the yellow stone are both moving with a speed of 1.0 m/s.

c) The red stone bounces off the yellow stone and moves with a speed of 2.0 m/s, and the yellow stone remains at rest.

7.11 For a totally elastic collision between two objects, which of the following statements is (are) true?

a) The total mechanical energy is conserved.

b) The total kinetic energy is conserved.

c) The total momentum is conserved.

d) The momentum of each object is conserved.

e) The kinetic energy of each object is conserved.

7.12 For a totally inelastic collision between two objects, which of the following statements is (are) true?

a) The total mechanical energy is conserved.

b) The total kinetic energy is conserved.

c) The total momentum is conserved.

d) The total momentum after the collision is always zero.

e) The total kinetic energy after the collision can never be zero.

7.13 A ballistic pendulum is used to measure the speed of a bullet shot from a gun. The mass of the bullet is 50.0 g, and the mass of the block is 20.0 kg. When the bullet strikes the block, the combined mass rises a vertical distance of 5.00 cm. What was the speed of the bullet as it struck the block?

a) 397 m/s

b) 426 m/s

c) 457 m/s

d) 479 m/s

e) 503 m/s

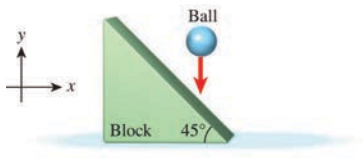
CONCEPTUAL QUESTIONS

7.14 An astronaut becomes stranded during a space walk after her jet pack malfunctions. Fortunately, there are two objects close to her that she can push to propel herself back to the International Space Station (ISS). Object A has the same mass as the astronaut, and Object B is 10 times more massive. To achieve a given momentum toward the ISS by pushing one of the objects away from the ISS, which object should she push? That is, which one requires less work to produce the same impulse? Initially, the astronaut and the two objects are at rest with respect to the ISS. (*Hint:* Recall that work is force times distance and think about how the two objects move when they are pushed.)

7.15 Consider a ballistic pendulum (see Section 7.6) in which a bullet strikes a block of wood. The wooden block is hanging from the ceiling and swings up to a maximum height after the bullet strikes it. Typically, the bullet becomes embedded in the block. Given the same bullet, the same initial bullet speed, and the same block, would the maximum height of the block change if the bullet did not get stopped by the block but passed through to the other side? Would the height change if the bullet and its speed were the same but the block was steel and the bullet bounced off it, directly backward?

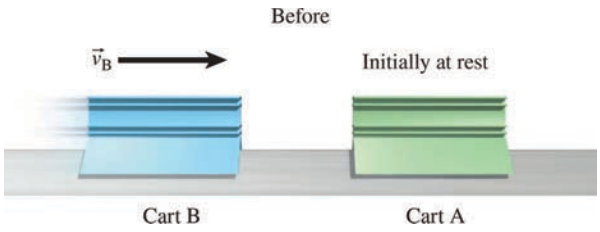
7.16 A bungee jumper is concerned that his elastic cord might break if it is overstretched and is considering replacing the cord with a high-tensile-strength steel cable. Is this a good idea?

7.17 A ball falls straight down onto a block that is wedge-shaped and is sitting on frictionless ice. The block is initially at rest (see the figure). Assuming the collision is perfectly elastic, is the total momentum of the block/ball system conserved? Is the total kinetic energy of the block/ball system exactly the same before and after the collision? Explain.

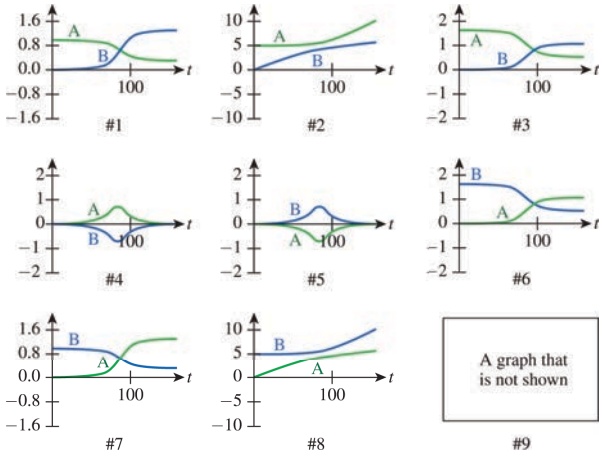


7.18 To solve problems involving projectiles traveling through the air by applying the law of conservation of momentum requires evaluating the momentum of the system *immediately* before and *immediately* after the collision or explosion. Why?

7.19 Two carts are riding on an air track as shown in the figure. At time $t = 0$, cart B is at the origin traveling in the positive x-direction with speed v_B, and cart A is at rest as shown in the diagram. The carts collide but do not stick.



Each of the graphs depicts a possible plot of a physical parameter with respect to time. Each graph has two curves, one for each cart, and each curve is labeled with the cart's letter. For each property (a)–(e), specify the graph that could be a plot of the property; if a graph for a property is not shown, choose alternative 9.



a) the forces *exerted by* the carts

b) the positions of the carts

c) the velocities of the carts

d) the accelerations of the carts

e) the momenta of the carts

7.20 Using momentum and force principles, explain why an air bag reduces injury in an automobile collision.

7.21 A rocket works by expelling gas (fuel) from its nozzles at a high velocity. However, if we take the system to be the rocket and fuel, explain qualitatively why a stationary rocket is able to move.

7.22 When hit in the face, a boxer will "ride the punch"; that is, if he anticipates the punch, he will start moving his head backward before the fist arrives. His head then moves back easily from the blow. From a momentum-impulse standpoint, explain why this is much better than stiffening his neck muscles and bracing himself against the punch.

7.23 An open train car moves with speed v_0 on a flat frictionless railroad track, with no engine pulling it. It begins to rain. The rain falls straight down and begins

to fill the train car. Does the speed of the car decrease, increase, or stay the same? Explain.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One · and two ·· indicate increasing level of problem difficulty.

Section 7.1

7.24 Rank the following objects from highest to lowest in terms of momentum and from highest to lowest in terms of energy.

a) an asteroid with mass 10^6 kg and speed 500 m/s

b) a high-speed train with a mass of 180,000 kg and a speed of 300 km/h

c) a 120-kg linebacker with a speed of 10 m/s

d) a 10-kg cannonball with a speed of 120 m/s

e) a proton with a mass of $2 \cdot 10^{-27}$ kg and a speed of $2 \cdot 10^8$ m/s

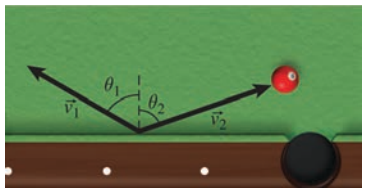
7.25 A car of mass 1200. kg, moving with a speed of 72.0 mph on a highway, passes a small SUV with a mass $1\frac{1}{2}$ times bigger, moving at 2/3 the speed of the car.

a) What is the ratio of the momentum of the SUV to that of the car?

b) What is the ratio of the kinetic energy of the SUV to that of the car?

7.26 The electron-volt (eV) is a unit of energy $\left(1\text{eV} = 1.602 \cdot 10^{-19}\ \text{J}, 1\text{MeV} = 1.602 \cdot 10^{-13}\ \text{J}\right)$. Since the unit of momentum is an energy unit divided by a velocity unit, nuclear physicists usually specify momenta of nuclei in units of MeV/c, where c is the speed of light $(c = 2.998 \cdot 108\text{m/s})$. In the same units, the mass of a proton $\left(1.673 \cdot 10^{-27}\ \text{kg}\right)$ is given as 938.3 MeV $/c^2$. If a proton moves with a speed of 17,400 km/s, what is its momentum in units of MeV/c?

7.27 A soccer ball with a mass of 442 g bounces off the crossbar of a goal and is deflected upward at an angle of 58.0° with respect to horizontal. Immediately after the deflection, the kinetic energy of the ball is 49.5 J. What are the vertical and horizontal components of the ball's momentum immediately after striking the crossbar?



•**7.28** A billiard ball of mass m = 0.250 kg hits the cushion of a billiard table at an angle of $\theta_1 = 60.0^\circ$ and a speed of $v_1 = 27.0$ m/s. It bounces off at an angle of $\theta_2 = 71.0^\circ$ and a speed of $v_2 = 10.0$ m/s.

a) What is the magnitude of the change in momentum of the billiard ball?

b) In which direction does the change-of-momentum vector point?

Section 7.2

7.29 In the movie *Superman,* Lois Lane falls from a building and is caught by the diving superhero. Assuming that Lois, with a mass of 50.0 kg, is falling at a terminal velocity of 60.0 m/s, how much average force is exerted on her if it takes 0.100 s to slow her to a stop? If Lois can withstand a maximum acceleration of 7.00 *g*'s, what minimum time should it take Superman to stop her after he begins to slow her down?

7.30 One of the events in the Scottish Highland Games is the sheaf toss, in which a 9.09-kg bag of hay is tossed straight up into the air using a pitchfork. During one throw, the sheaf is launched straight up with an initial speed of 2.70 m/s.

a) What is the impulse exerted on the sheaf by gravity during the upward motion of the sheaf (from launch to maximum height)?

b) Neglecting air resistance, what is the impulse exerted by gravity on the sheaf during its downward motion (from maximum height until it hits the ground)?

c) Using the total impulse produced by gravity, determine how long the sheaf is airborne.

7.31 An 83.0-kg running back leaps straight ahead toward the end zone with a speed of 6.50 m/s. A 115-kg linebacker, keeping his feet on the ground, catches the running back and applies a force of 900. N in the opposite direction for 0.750 s before the running back's feet touch the ground.

a) What is the impulse that the linebacker imparts to the running back?

b) What change in the running back's momentum does the impulse produce?

c) What is the running back's momentum when his feet touch the ground?

d) If the linebacker keeps applying the same force after the running back's feet have touched the ground, is this still the only force acting to change the running back's momentum?

7.32 A baseball pitcher delivers a fastball that crosses the plate at an angle of 7.25° below the horizontal and a speed of 88.5 mph. The ball (of mass 0.149 kg) is hit back over the head of the pitcher at an angle of 35.53° above the horizontal and a speed of 102.7 mph. What is the magnitude of the impulse received by the ball?

•**7.33** Although they don't have mass, photons—traveling at the speed of light—have momentum. Space travel experts have thought of capitalizing on this fact by constructing *solar sails*—large sheets of material that would work by reflecting photons. Since the momentum of the photon would be reversed, an impulse would be exerted on it by the solar sail, and—by Newton's Third Law—an impulse would also be exerted on the sail, providing a force. In space near the Earth, about $3.84 \cdot 10^{21}$ photons are incident per square meter per second. On average, the momentum of each photon is $1.30 \cdot 10^{-27}$ kg m/s. For a 1000.-kg spaceship starting from rest and attached to a square sail 20.0 m wide, how fast could the

ship be moving after 1 hour? After 1 week? After 1 month? How long would it take the ship to attain a speed of 8000. m/s, roughly the speed of a space shuttle in orbit?

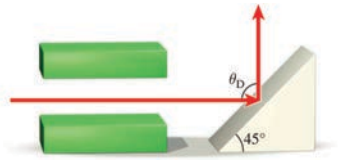
•**7.34** In a severe storm, 1.00 cm of rain falls on a flat horizontal roof in 30.0 min. If the area of the roof is 100. m_2 and the terminal velocity of the rain is 5.00 m/s, what is the average force exerted on the roof by the rain during the storm?

•**7.35** NASA has taken an increased interest in near-Earth asteroids. These objects, popularized in certain blockbuster movies, can pass very close to Earth on a cosmic scale, sometimes as close as 1 million miles. Most are small—less than 500 m across—and while an impact with one of the smaller ones could be dangerous, experts believe that it may not be catastrophic to the human race. One possible defense system against near-Earth asteroids involves hitting an incoming asteroid with a rocket to divert its course. Assume a relatively small asteroid with a mass of $2.10 \cdot 10^{10}$ kg is traveling toward the Earth at a modest speed of 12.0 km/s.

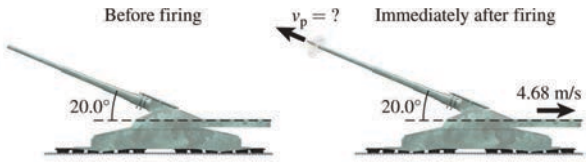
a) How fast would a large rocket with a mass of $8.00 \cdot 10^{4}$ kg have to be moving when it hit the asteroid head-on in order to stop the asteroid? Assume that the rocket and the asteroid stick together after colliding.

b) An alternative approach would be to divert the asteroid from its path by a small amount and thus cause it to miss Earth. How fast would the rocket of part (a) have to be traveling at impact to divert the asteroid's path by 1.00°? In this case, assume that the rocket hits the asteroid while traveling along a line perpendicular to the asteroid's path.

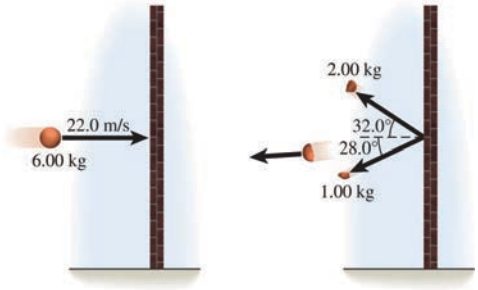
•**7.36** In nanoscale electronics, electrons can be treated like billiard balls. The figure shows a simple device currently under study in which an electron elastically collides with a rigid wall (a ballistic electron transistor). The green bars represent electrodes that can apply a vertical force of $8.00 \cdot 10^{-13}$ N to the electrons. If an electron initially has velocity components $v_x = 1.00 \cdot 10^{5}$ m/s and $v_y = 0$ and the wall is at 45.0°, the deflection angle θ_D is 90.0°. How long does the vertical force from the electrodes need to be applied to obtain a deflection angle of 120.°?



•**7.37** The largest railway gun ever built was called Gustav and was used briefly in World War II. The gun, mount, and train car had a total mass of $1.22 \cdot 10^{6}$ kg. The gun fired a projectile that was 80.0 cm in diameter and weighed 7502 kg. In the firing illustrated in the figure, the gun has been elevated 20.0° above the horizontal. If the railway gun was at rest before firing and moved to the right at a speed of 4.68 m/s immediately after firing, what was the speed of the projectile as it left the barrel (muzzle velocity)? How far will the projectile travel if air resistance is neglected? Assume that the wheel axles are frictionless.



••**7.38** A 6.00-kg clay ball is thrown directly against a perpendicular brick wall at a velocity of 22.0 m/s and shatters into three pieces, which all fly backward, as shown in the figure. The wall exerts a force on the ball of 2640 N for 0.100 s. One piece of mass 2.00 kg travels backward at a velocity of 10.0 m/s and an angle of 32.0° above the horizontal. A second piece of mass 1.00 kg travels at a velocity of 8.00 m/s and an angle of 28.0° below the horizontal. What is the velocity of the third piece?



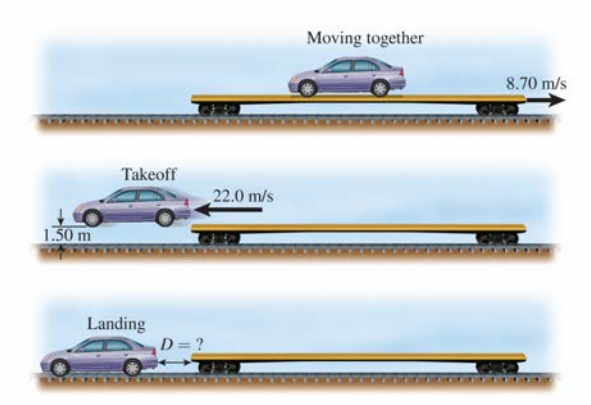
Section 7.3

7.39 A sled initially at rest has a mass of 52.0 kg, including all of its contents. A block with a mass of 13.5 kg is ejected to the left at a speed of 13.6 m/s. What is the speed of the sled and the remaining contents?

7.40 Stuck in the middle of a frozen pond with only your physics book, you decide to put physics in action and throw the 5.00-kg book. If your mass is 62.0 kg and you throw the book at 13.0 m/s, how fast do you then slide across the ice? (Assume the absence of friction.)

7.41 Astronauts are playing baseball on the International Space Station. One astronaut with a mass of 50.0 kg, initially at rest, hits a baseball with a bat. The baseball was initially moving toward the astronaut at 35.0 m/s, and after being hit, travels back in the same direction with a speed of 45.0 m/s. The mass of a baseball is 0.140 kg. What is the recoil velocity of the astronaut?

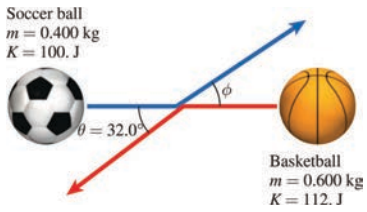
•**7.42** An automobile with a mass of 1450 kg is parked on a moving flatbed railcar; the flatbed is 1.50 m above the ground. The railcar has a mass of 38,500 kg and is moving to the right at a constant speed of 8.70 m/s on a frictionless rail. The automobile then accelerates to the left, leaving the railcar at a speed of 22.0 m/s with respect to the ground. When the automobile lands, what is the distance *D* between it and the left end of the railcar? See the figure.



•**7.43** Three people are floating on a 120.-kg raft in the middle of a pond on a warm summer day. They decide to go swimming, and all jump off the raft at the same time and from evenly spaced positions around the perimeter of the raft. One person, with a mass of 62.0 kg, jumps off the raft at a speed of 12.0 m/s. The second person, of mass 73.0 kg, jumps off the raft at a speed of 8.00 m/s. The third person, of mass 55.0 kg, jumps off the raft at a speed of 11.0 m/s. At what speed does the raft drift from its original position?

•**7.44** A missile is shot straight up into the air. At the peak of its trajectory, it breaks up into three pieces of equal mass, all of which move horizontally away from the point of the explosion. One piece travels in a horizontal direction of 28.0° east of north with a speed of 30.0 m/s. The second piece travels in a horizontal direction of 12.0° south of west with a speed of 8.00 m/s. What is the velocity of the remaining piece? Give both speed and angle.

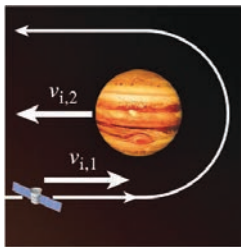
••**7.45** Once a favorite playground sport, dodgeball is becoming increasingly popular among adults of all ages who want to stay in shape and who even form organized leagues. Gutball is a less popular variant of dodgeball in which players are allowed to bring their own (typically nonregulation) equipment and in which cheap shots to the face are permitted. In a gutball tournament against people half his age, a physics professor threw his 0.400-kg soccer ball at a kid throwing a 0.600-kg basketball. The balls collided in midair (see the figure), and the basketball flew off with an energy of 95.0 J at an angle of 32.0° relative to its initial path. Before the collision, the energy of the soccer ball was 100. J and the energy of the basketball was 112 J. At what angle and speed did the soccer ball move away from the collision?



Section 7.4

7.46 Two bumper cars moving on a frictionless surface collide elastically. The first bumper car is moving to the right with a speed of 20.4 m/s and rear-ends the second bumper car, which is also moving to the right but with a speed of 9.00 m/s. What is the speed of the first bumper car after the collision? The mass of the first bumper car is 188 kg, and the mass of the second bumper car is 143 kg. Assume that the collision takes place in one dimension.

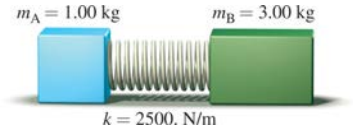
7.47 A satellite with a mass of 274 kg approaches a large planet at a speed $v_{i,1} = 13.5 \text{ km/s}$. The planet is moving at a speed $v_{i,2} = 10.5 \text{ km/s}$ in the opposite direction. The satellite partially orbits the planet and then moves away from the planet in a direction opposite to its original direction (see the figure). If this interaction is assumed to approximate an elastic collision in one dimension, what is the speed of the satellite after the collision? This so-called *slingshot effect* is often used to accelerate space probes for journeys to distance parts of the Solar System (see Chapter 12).



Martin Adams/iStockphoto/Getty Images

•**7.48** You see a pair of shoes tied together by the laces and hanging over a telephone line. You throw a 0.250-kg stone at one of the shoes (mass = 0.370 kg), and it collides elastically with the shoe with a velocity of 2.30 m/s in the horizontal direction. How far up does the shoe move?

•**7.49** Block A and block B are forced together, compressing a spring (with spring constant k = 2500. N/m) between them 3.00 cm from its equilibrium length. The spring, which has negligible mass, is not fastened to either block and drops to the surface after it has expanded. What are the speeds of block A and block B at this moment? (Assume that the friction between the blocks and the supporting surface is so low that it can be neglected.)



•**7.50** An alpha particle (mass = 4.00 u) has a head-on, elastic collision with a nucleus (mass = 166 u) that is initially at rest. What percentage of the kinetic energy of the alpha particle is transferred to the nucleus in the collision?

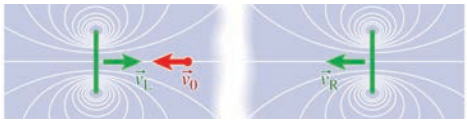
•**7.51** You notice that a shopping cart 20.0 m away is moving with a velocity of 0.700 m/s toward you. You launch an identical cart with a velocity of 1.10 m/s directly at the other cart in order to intercept it. When the two carts collide elastically, they remain in contact for 0.200 s. Graph the position, velocity, and force for both carts as a function of time.

•**7.52** A 0.280-kg ball has an elastic, head-on collision with a second ball that is initially at rest. The second ball moves off with half the original speed of the first ball.

a) What is the mass of the second ball?

b) What fraction of the original kinetic energy $(\Delta K/K)$ is transferred to the second ball?

••**7.53** Cosmic rays from space that strike Earth contain some charged particles with energies billions of times higher than any that can be produced in the biggest accelerator. One model that was proposed to account for these particles is shown schematically in the figure. Two very strong sources of magnetic fields move toward each other and repeatedly reflect the charged particles trapped between them. These magnetic field sources can be approximated as infinitely heavy walls from which charged particles get reflected elastically. The high-energy particles that strike the Earth would have been reflected a large number of times to attain the observed energies. An analogous case with only a few reflections demonstrates this effect. Suppose a particle has an initial velocity of −2.21 km/s (moving in the negative *x*-direction, to the left), the left wall moves with a velocity of 1.01 km/s to the right, and the right wall moves with a velocity of 2.51 km/s to the left. What is the velocity of the particle after six collisions with the left wall and five collisions with the right wall?



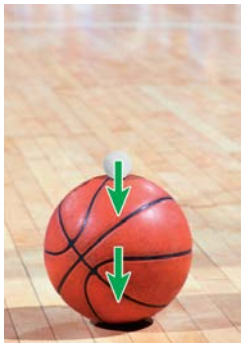
••**7.54** Here is a popular lecture demonstration that you can perform at home. Place a golf ball on top of a basketball, and drop the pair from rest so they fall to the ground. (For reasons that should become clear once you solve this problem, do not attempt to do this experiment inside, but outdoors instead!) With a little practice, you can achieve the situation pictured here: The golf ball stays on top of the basketball until the basketball hits the floor. The mass of the golf ball is 0.0459 kg, and the mass of the basketball is 0.619 kg.

a) If the balls are released from a height where the bottom of the basketball is at 0.701 m above the ground, what is the absolute value of the basketball's momentum just before it hits the ground?

b) What is the absolute value of the momentum of the golf ball at this instant?

c) Treat the collision of the basketball with the floor and the collision of the golf ball with the basketball as totally elastic collisions in one dimension. What is the absolute magnitude of the momentum of the golf ball after these collisions?

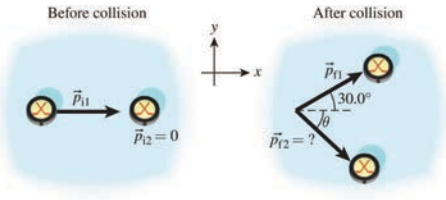
d) Now comes the interesting question: How high, measured from the ground, will the golf ball bounce up after its collision with the basketball?



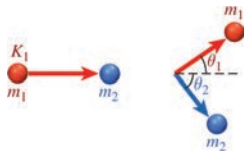
PhotoLink/Getty Images

Section 7.5

7.55 A hockey puck with mass 0.170 kg traveling along the blue line (a blue-colored straight line on the ice in a hockey rink) at 1.50 m/s strikes a stationary puck with the same mass. The first puck exits the collision in a direction that is 30.0° away from the blue line at a speed of 0.750 m/s (see the figure). What is the direction and magnitude of the velocity of the second puck after the collision? Is this an elastic collision?

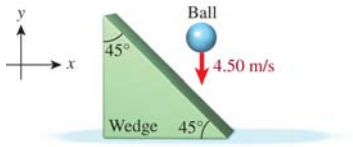


•**7.56** A ball with mass m = 0.210 kg and kinetic energy $K_1 = 2.97$ J collides elastically with a second ball of the same mass that is initially at rest. After the collision, the first ball moves away at an angle of $\theta_1 = 30.6°$ with respect to the horizontal, as shown in the figure. What is the kinetic energy of the first ball after the collision?

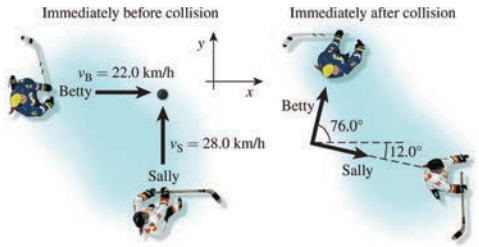


•7.57 When you open the door to an air-conditioned room, you mix hot gas with cool gas. Saying that a gas is hot or cold actually refers to its average energy; that is, the hot gas molecules have a higher kinetic energy than the cold gas molecules. The difference in kinetic energy in the mixed gases decreases over time as a result of elastic collisions between the gas molecules, which redistribute the energy. Consider a two-dimensional collision between two nitrogen molecules (N_2, molecular weight = 28.0 g/mol). One molecule moves to the right and upward at 30.0° with respect to the horizontal with a velocity of 672 m/s. This molecule collides with a second molecule moving in the negative horizontal direction at 246 m/s. What are the molecules' final velocities if the one that is initially more energetic moves in the positive vertical direction after the collision?

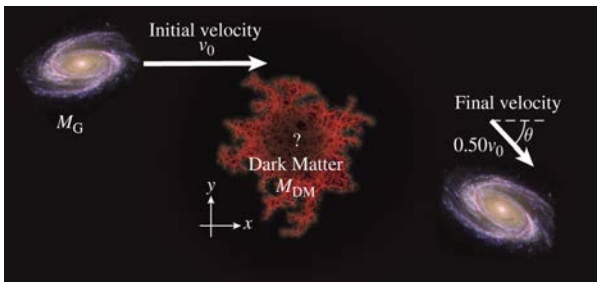
•**7.58** A ball with mass 3.00 kg falls straight down onto a 45°-wedge that is rigidly attached to the ground. The ball is moving a speed of 4.50 m/s when it strikes the wedge. Assuming that the collision is instantaneous and perfectly elastic, what is the recoil momentum that the Earth receives during this collision?



••**7.59** Betty Bodycheck ($m_B = 55.0\ \text{kg},\ v_B = 22.0\ \text{km/h}$ in the positive x-direction) and Sally Slasher ($m_S = 45.0\ \text{kg}, v_S = 28.0\ \text{km/h}$ in the positive y-direction) are both racing to get to a hockey puck. Immediately after the collision, Betty is heading in a direction that is 76.0° counterclockwise from her original direction, and Sally is heading back and to her right in a direction that is 12.0° from the x-axis. What are Betty and Sally's final kinetic energies? Is their collision elastic?



••**7.60** Current measurements and cosmological theories suggest that only about 4.6% of the total mass of the universe is composed of ordinary matter. About 23.% of the mass is composed of *dark matter,* which does not emit or reflect light and can only be observed through its gravitational interaction with its surroundings (see Chapter 12). Suppose a galaxy with mass M_G is moving in a straight line in the x-direction. After it interacts with an invisible clump of dark matter with mass M_{DM}, the galaxy moves with 50.% of its initial speed in a straight line in a direction that is rotated by an angle θ from its initial velocity. Assume that initial and final velocities are given for positions where the galaxy is very far from the clump of dark matter, that the gravitational attraction can be neglected at those positions, and that the dark matter is initially at rest. Determine M_{DM} terms of M_G, v_0, and θ.



NASA

Section 7.6

7.61 A 1439-kg railroad car traveling at a speed of 12.0 m/s strikes an identical car at rest. If the cars lock together as a result of the collision, what is their common speed (in m/s) afterward?

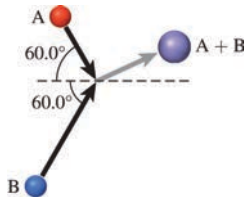
7.62 Bats are extremely adept at catching insects in midair. If a 50.0-g bat flying in one direction at 8.00 m/s catches a 5.00-g insect flying in the opposite direction at 6.00 m/s, what is the speed of the bat immediately after catching the insect?

•**7.63** A small car of mass 1000. kg traveling at a speed of 33.0 m/s collides head-on with a large car of mass 3000. kg traveling in the opposite direction at a speed of 30.0 m/s. The two cars stick together. The duration of the collision is 100. ms. What acceleration (in g) do the occupants of the small car experience? What acceleration (in g) do the occupants of the large car experience?

•**7.64** To determine the muzzle velocity of a bullet fired from a rifle, you shoot the 2.00-g bullet into a 2.00-kg wooden block. The block is suspended by wires from the ceiling and is initially at rest. After the bullet is embedded in the block, the block swings up to a maximum height of 0.500 cm above its initial position. What is the velocity of the bullet on leaving the gun's barrel?

•7.65 A 2000.-kg Cadillac and a 1000.-kg Volkswagen meet at an intersection. The stoplight has just turned green, and the Cadillac, heading north, drives forward into the intersection. The Volkswagen, traveling east, fails to stop. The Volkswagen crashes into the left front fender of the Cadillac; then the cars stick together and slide to a halt. Officer Tom, responding to the accident, sees that the skid marks are directed 55.0° north of east from the point of impact. The driver of the Cadillac, who keeps a close eye on the speedometer, reports that he was traveling at 30.0 m/s when the accident occurred. How fast was the Volkswagen going just before the impact?

•**7.66** Two balls of equal mass collide and stick together as shown in the figure. The initial velocity of ball B is twice that of ball A.

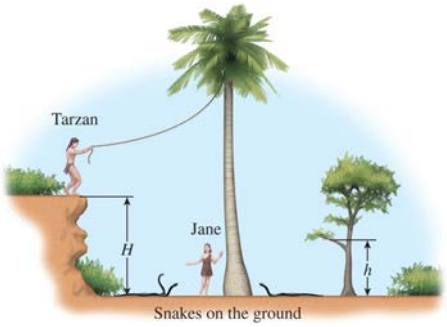


a) Calculate the angle above the horizontal of the motion of mass A + B after the collision.

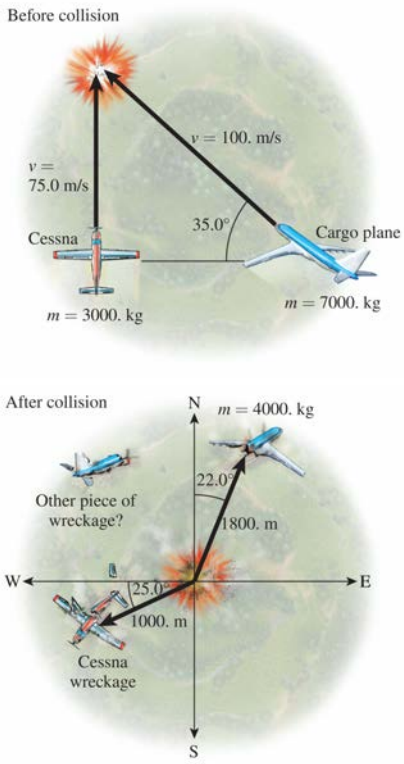
b) What is the ratio of the final velocity of the mass A + B to the initial velocity of ball A, v_f/v_A?

c) What is the ratio of the final energy of the system to the initial energy of the system, E_f/E_i?

••**7.67** Tarzan swings on a vine from a cliff to rescue Jane, who is standing on the ground surrounded by snakes. His plan is to push off the cliff, grab Jane at the lowest point of his swing, and carry them both to the safety of a nearby tree (see the figure). Tarzan's mass is 80.0 kg, Jane's mass is 40.0 kg,
the height of the lowest limb of the target tree is 10.0 m, and Tarzan is initially standing on a cliff of height 20.0 m. The length of the vine is 30.0 m. With what speed should Tarzan push off the cliff if he and Jane are to make it to the tree limb successfully?



••**7.68** A 3000.-kg Cessna airplane flying north at 75.0 m/s at an altitude of 1600. m over the jungles of Brazil collided with a 7000.-kg cargo plane flying 35.0° north of west with a speed of 100. m/s. As measured from a point on the ground directly below the collision, the Cessna wreckage was found 1000. m away at an angle of 25.0° south of west, as shown in the figure. The cargo plane broke into two pieces. Rescuers located a 4000.-kg piece 1800. m away from the same point at an angle of 22.0° east of north. Where should they look for the other piece of the cargo plane? Give a distance and a direction from the point directly below the collision.



Section 7.7

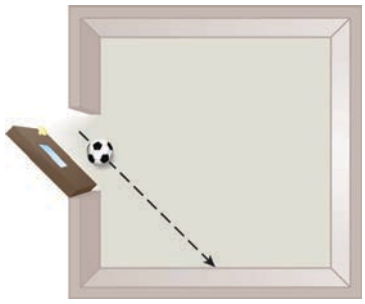
7.69 The objects listed in the table are dropped from a height of 85 cm. The height they reach after bouncing has been recorded. Determine the coefficient of restitution for each object.

Object	H **(cm)**	h_1 **(cm)**	ϵ
Range golf ball	85.0	62.6	
Tennis ball	85.0	43.1	
Billiard ball	85.0	54.9	
Handball	85.0	48.1	
Wooden ball	85.0	30.9	
Steel ball bearing	85.0	30.3	
Glass marble	85.0	36.8	
Ball of rubber bands	85.0	58.3	
Hollow, hard plastic ball	85.0	40.2	

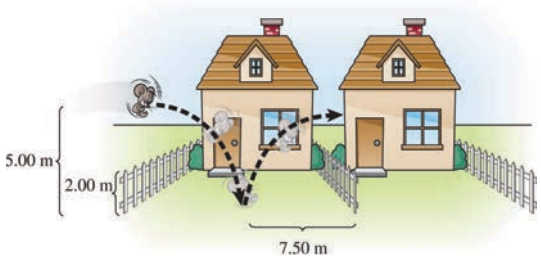
7.70 A golf ball is released from rest from a height of 0.811 m above the ground and has a collision with the ground, for which the coefficient of restitution is 0.601. What is the maximum height reached by this ball as it bounces back up after this collision?

•**7.71** A billiard ball of mass 0.162 kg has a speed of 1.91 m/s and collides with the side of the billiard table at an angle of 35.9° with respect to the normal. For this collision, the coefficient of restitution is 0.841. What is the angle relative to the side (in degrees) at which the ball moves away from the collision?

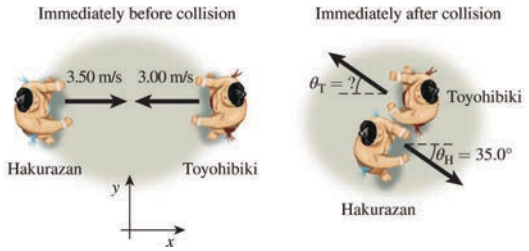
•**7.72** A soccer ball rolls out of a gym through the center of a doorway into the next room. The adjacent room is 6.00 m by 6.00 m with the 2.00-m wide doorway located at the center of the wall. The ball hits the center of a side wall at 45.0°. If the coefficient of restitution for the soccer ball is 0.850, does the ball bounce back out of the room? (Note that the ball rolls without slipping, so no energy is lost to the floor.)



•7.73 In a *Tom and Jerry*™ cartoon, Tom the cat is chasing Jerry the mouse outside in a yard. The house is in a neighborhood where all the houses are exactly the same, each with the same size yard and the same 2.00-m-high fence around each yard. In the cartoon, Tom rolls Jerry into a ball and throws him over the fence. Jerry moves like a projectile, bounces at the center of the next yard, and continues to fly toward the next fence, which is 7.50 m away. If Jerry's original height above ground when he was thrown is 5.00 m, his original range is 15.0 m, and his coefficient of restitution is 0.80, does he make it over the next fence?



••7.74 Two Sumo wrestlers are involved in an inelastic collision. The first wrestler, Hakurazan, has a mass of 135 kg and moves forward along the positive x-direction at a speed of 3.50 m/s. The second wrestler, Toyohibiki, has a mass of 173 kg and moves straight toward Hakurazan at a speed of 3.00 m/s. Immediately after the collision, Hakurazan is deflected to his right by 35.0° (see the figure). In the collision, 10.0% of the wrestlers' initial total kinetic energy is lost. What is the angle at which Toyohibiki is moving immediately after the collision?



••7.75 A hockey puck (m = 170. g and $v_0 = 2.00$ m/s) slides without friction on the ice and hits the rink board at 30.0° with respect to the normal. The puck bounces off the board at a 40.0° angle with respect to the normal. What is the coefficient of restitution for the puck? What is the ratio of the puck's final kinetic energy to its initial kinetic energy?

Additional Exercises

7.76 How fast would a 5.00-g fly have to be traveling to slow a 1900.-kg car traveling at 55.0 mph by 5.00 mph if the fly hit the car in a totally inelastic head-on collision?

7.77 Attempting to score a touchdown, an 85.0-kg tailback jumps over his blockers, achieving a horizontal speed of 8.90 m/s. He is met in midair just short of the goal line by a 110.-kg linebacker traveling in the opposite direction at a speed of 8.00 m/s. The linebacker grabs the tailback.

a) What is the speed of the entangled tailback and linebacker just after the collision?

b) Will the tailback score a touchdown (provided that no other player has a chance to get involved, of course)?

7.78 The nucleus of radioactive thorium-228, with a mass of about $3.78 \cdot 10^{-25}$ kg, is known to decay by emitting an alpha particle with a mass of about $6.64 \cdot 10^{-27}$ kg. If the alpha particle is emitted with a speed of $1.80 \cdot 10^{7}$ m/s, what is the recoil speed of the remaining nucleus (which is the nucleus of a radon atom)?

7.79 A 60.0-kg astronaut inside a 7.00-m-long space capsule of mass 500. kg is floating weightlessly on one end of the capsule. He kicks off the wall at a velocity of 3.50 m/s toward the other end of the capsule. How long does it take the astronaut to reach the far wall?

7.80 Moessbauer spectroscopy is a technique for studying molecules by looking at a particular atom within them. For example, Moessbauer measurements of iron (Fe) inside hemoglobin, the molecule responsible for transporting oxygen in the blood, can be used to determine the hemoglobin's flexibility. The technique starts with X-rays emitted from the nuclei of ^{57}Co atoms. These X-rays are then used to study the Fe in the hemoglobin. The energy and momentum of each X-ray are 14.0 keV and 14.0 keV/c (see Example 7.5 for an explanation of the units). A ^{57}Co nucleus recoils as an X-ray is emitted. A single ^{57}Co nucleus has a mass of $9.52 \cdot 10^{-26}$ kg. What are the final momentum and kinetic energy of the ^{57}Co nucleus? How do these compare to the values for the X-ray?

7.81 Assume the nucleus of a radon atom, ^{222}Rn, has a mass of $3.68 \cdot 10^{-25}$ kg. This radioactive nucleus decays by emitting an alpha particle with an energy of $8.79 \cdot 10^{-13}$ J. The mass of an alpha particle is $6.64 \cdot 10^{-13}$ J. Assuming that the radon nucleus was initially at rest, what is the velocity of the nucleus that remains after the decay?

7.82 A skateboarder of mass 35.0 kg is riding her 3.50-kg skateboard at a speed of 5.00 m/s. She jumps backward off her skateboard, sending the skateboard forward at a speed of 8.50 m/s. At what speed is the skateboarder moving when her feet hit the ground?

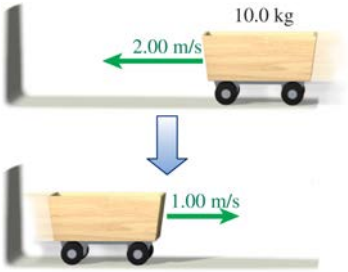
7.83 During an ice-skating extravaganza, *Robin Hood on Ice,* a 50.0-kg archer is standing still on ice skates. Assume that the friction between the ice skates and the

ice is negligible. The archer shoots a 0.100-kg arrow horizontally at a speed of 95.0 m/s. At what speed does the archer recoil?

7.84 Astronauts are playing catch on the International Space Station. One 55.0-kg astronaut, initially at rest, throws a baseball of mass 0.145 kg at a speed of 31.3 m/s. At what speed does the astronaut recoil?

7.85 A bungee jumper with mass 55.0 kg reaches a speed of 13.3 m/s moving straight down when the elastic cord tied to her feet starts pulling her back up. After 1.25 s, the jumper is heading back up at a speed of 10.5 m/s. What is the average force that the bungee cord exerts on the jumper? What is the average number of *g*'s that the jumper experiences during this direction change?

7.86 A 3.00-kg ball of clay with a speed of 21.0 m/s is thrown against a wall and sticks to the wall. What is the magnitude of the impulse exerted on the ball?



7.87 The figure shows before and after scenes of a cart colliding with a wall and bouncing back. What is the cart's change of momentum? (Assume that right is the positive direction in the coordinate system.)

7.88 Tennis champion Venus Williams is capable of serving a tennis ball at around 127 mph.

a) Assuming that her racquet is in contact with the 57.0-g ball for 0.250 s, what is the average force of the racquet on the ball?

b) What average force would an opponent's racquet have to exert in order to return Williams's serve at a speed of 50.0 mph, assuming that the opponent's racquet is also in contact with the ball for 0.250 s?

7.89 Three birds are flying in a compact formation. The first bird, with a mass of 100. g, is flying 35.0° east of north at a speed of 8.00 m/s. The second bird, with a mass of 123 g, is flying 2.00° east of north at a speed of 11.0 m/s. The third bird, with a mass of 112 g, is flying 22.0° west of north at a speed of 10.0 m/s. What is the momentum vector of the formation? What would be the speed and direction of a 115-g bird with the same momentum?

7.90 A golf ball of mass 45.0 g moving at a speed of 120. km/h collides head on with a French TGV high-speed train of mass $3.80 \cdot 10^5$ kg that is traveling at 300. km/h. Assuming that the collision is elastic, what is the speed of the golf ball after the collision? (Do not try to conduct this experiment!)

7.91 In bocce, the object of the game is to get your balls (each with mass M = 1.00 kg) as close as possible to the small white ball (the *pallina,* mass m = 0.0450 kg). Your first throw positioned your ball 2.00 m to the left of the pallina. If your next

throw arrives with a speed of v = 1.00 m/s and the coefficient of kinetic friction is $\mu_k = 0.200$, what are the final distances of your two balls from the pallina in each of the following cases? Assume that collisions are elastic.

a) You throw your ball from the left, hitting your first ball.

b) You throw your ball from the right, hitting the pallina.

(*Hint:* Use the fact that $m \ll M$, and ignore ball diameters.)

•**7.92** A bored boy shoots a soft pellet from an air gun at a piece of cheese with mass 0.250 kg that sits, keeping cool for dinner guests, on a block of ice. On one particular shot, his 1.20-g pellet gets stuck in the cheese, causing it to slide 25.0 cm before coming to a stop. According to the package the gun came in, the muzzle velocity is 65.0 m/s. What is the coefficient of friction between the cheese and the ice?

•**7.93** Some kids are playing a dangerous game with fireworks. They strap several firecrackers to a toy rocket and launch it into the air at an angle of 60.0° with respect to the ground. At the top of its trajectory, the contraption explodes, and the rocket breaks into two equal pieces. One of the pieces has half the speed that the rocket had before it exploded and travels straight upward with respect to the ground. Determine the speed and direction of the second piece.

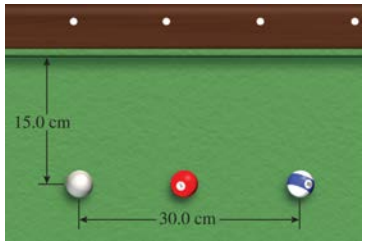
•**7.94** A ball with mass 0.265 kg is initially at rest and is kicked at an angle of 20.8° with respect to the horizontal. The ball travels through the air a horizontal distance of 52.8 m after it is kicked. What is the impulse received by the ball during the kick? Assume there is no air resistance.

•**7.95** Tarzan, King of the Jungle (mass = 70.4 kg), grabs a vine of length 14.5 m hanging from a tree branch. The angle of the vine was 25.9° with respect to the vertical when he grabbed it. At the lowest point of his trajectory, he picks up Jane (mass = 43.4 kg) and continues his swinging motion. What angle relative to the vertical will the vine have when Tarzan and Jane reach the highest point of their trajectory?

•**7.96** A bullet with mass 35.5 g is shot horizontally from a gun. The bullet embeds in a 5.90-kg block of wood that is suspended by strings. The combined mass swings upward, gaining a height of 12.85 cm. What was the speed of the bullet as it left the gun? (Air resistance can be ignored here.)

•**7.97** A 170.-g hockey puck moving in the positive x-direction at 30.0 m/s is struck by a stick at time t = 2.00 s and moves in the opposite direction at 25.0 m/s. If the puck is in contact with the stick for 0.200 s, plot the momentum and the position of the puck, and the force acting on it as a function of time, from 0 to 5.00 s. Be sure to label the coordinate axes with reasonable numbers.

•**7.98** Balls are sitting on a billiard table as shown in the figure. You are playing stripes, and your opponent is playing solids. Your plan is to hit your target ball by bouncing the white ball off the table bumper.

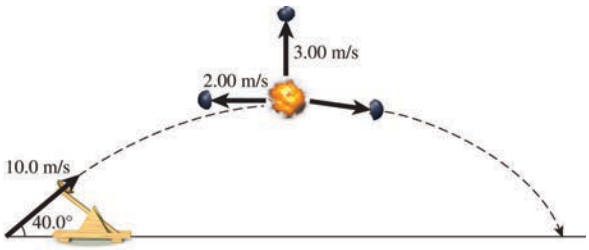


a) At what angle relative to the normal does the cue ball need to hit the bumper for a purely elastic collision?

b) As an ever observant player, you determine that in fact collisions between billiard balls and bumpers have a coefficient of restitution of 0.600. What angle do you now choose to make the shot?

•**7.99** You have dropped your cell phone behind a very long bookcase and cannot reach it from either the top or the sides. You decide to get the phone out by elastically colliding a set of keys with it so that both will slide out. If the mass of the cell phone is 0.111 kg, the key ring's mass is 0.020 kg, and each key's mass is 0.023 kg, what is the minimum number of keys you need on the ring so that both the keys and the cell phone will come out on the same side of the bookcase? If your key ring has five keys on it and the velocity is 1.21 m/s when it hits the cell phone, what are the final velocities of the cell phone and key ring? Assume the collision is one-dimensional and elastic, and neglect friction.

•**7.100** After several large firecrackers have been inserted into its holes, a bowling ball is projected into the air using a homemade launcher and explodes in midair. During the launch, the 7.00-kg ball is shot into the air with an initial speed of 10.0 m/s at a 40.0° angle; it explodes at the peak of its trajectory, breaking into three pieces of equal mass. One piece travels straight up with a speed of 3.00 m/s. Another piece travels straight back with a speed of 2.00 m/s. What is the velocity of the third piece (speed and direction)?

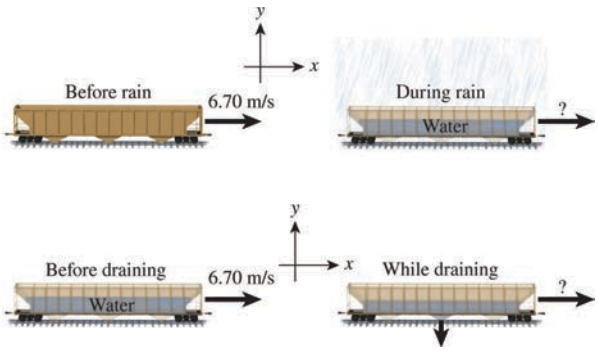


•**7.101** In waterskiing, a "garage sale" occurs when a skier loses control and falls and water skis fly in different directions. In one particular incident, a novice skier was skimming across the surface of the water at 22.0 m/s when he lost control. One ski, with a mass of 1.50 kg, flew off at an angle of 12.0° to the left of the initial direction of the skier with a speed of 25.0 m/s. The other identical ski flew from the crash at an angle of 5.00° to the right with a speed of 21.0 m/s. What was the velocity of the 61.0-kg skier? Give a speed and a direction relative to the initial velocity vector.

•**7.102** An uncovered hopper car from a freight train rolls without friction or air resistance along a level track at a constant speed of 6.70 m/s in the positive x-direction. The mass of the car is $1.18 \cdot 10^5$ kg.

a) As the car rolls, a monsoon rainstorm begins, and the car begins to collect water in its hopper (see the figure). What is the speed of the car after $1.62 \cdot 10^4$ kg of water collects in the car's hopper? Assume that the rain is falling vertically in the negative y-direction.

b) The rain stops, and a valve at the bottom of the hopper is opened to release the water. The speed of the car when the valve is opened is again 6.70 m/s in the positive x-direction (see the figure). The water drains out vertically in the negative y-direction. What is the speed of the car after all the water has drained out?



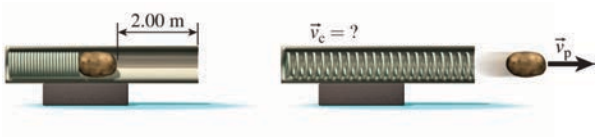
•**7.103** A rare isotope facility produces a beam of $7.25 \cdot 10^5$ nuclei per second of a rare isotope with mass $8.91 \cdot 10^{-26}$ kg. The nuclei are moving with 24.7% of the speed of light when they hit a beam stop (which is a block of materials that slows down the particles in the beam to zero speed). What is the magnitude of the average force that this beam exerts on the beam stop?

•**7.104** A student with a mass of 60.0 kg jumps straight up in the air by using her legs to apply an average force of 770. N to the ground for 0.250 s. Assume that the initial momentum of the student and the Earth are zero. What is the momentum of the student immediately after this impulse? What is the momentum of the Earth after this impulse? What is the speed of the Earth after the impulse? What fraction of the total kinetic energy that the student produces with her legs goes to the Earth (the mass of the Earth is $5.98 \cdot 10^{24}$ kg)? Using conservation of energy, how high does the student jump?

•**7.105** A potato cannon is used to launch a potato on a frozen lake, as shown in the figure. The mass of the cannon, m_c, is 10.0 kg, and the mass of the potato, m_p, is 0.850 kg. The cannon's spring (with spring constant $k_c = 7.06 \cdot 10^3$ N/m) is compressed 2.00 m. Prior to launching the potato, the cannon is at rest. The potato leaves the cannon's muzzle moving horizontally to the right at a speed of $v_p = 175$ m/s. Neglect the effects of the potato spinning. Assume there is no friction between the cannon and the lake's ice or between the cannon barrel and the potato.

a) What are the direction and magnitude of the cannon's velocity, v_c, after the potato leaves the muzzle?

b) What is the total mechanical energy (potential and kinetic) of the potato/cannon system before and after the firing of the potato?



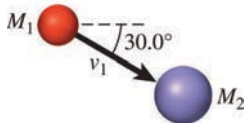
•**7.106** A potato cannon is used to launch a potato on a frozen lake, as in Exercise 7.105. All quantities are the same as in that problem, except the potato has a large diameter and is very rough, causing friction between the cannon barrel and the potato. The rough potato leaves the cannon's muzzle moving horizontally to the right at a speed of $v_p = 165$ m/s. Neglect the effects of the potato spinning.

a) What are the direction and magnitude of the cannon's velocity, v_c, after the rough potato leaves the muzzle?

b) What is the total mechanical energy (potential and kinetic) of the potato/cannon system before and after the firing of the potato?

c) What is the work, W_f, done by the force of friction on the rough potato?

•**7.107** A particle ($M_1 = 1.00$ kg) moving at 30.0° downward from the horizontal with $v_1 = 2.50$ m/s hits a second particle ($M_2 = 2.00$ kg), which is at rest. After the collision, the speed of M_1 is reduced to 0.500 m/s, and it is moving to the left and at an angle of 32.0° downward with respect to the horizontal. You cannot assume that the collision is elastic. What is the speed of M_2 after the collision?



••**7.108** Many nuclear collisions are truly elastic. If a proton with kinetic energy E_0 collides elastically with another proton at rest and travels at an angle of 25.0° with respect to its initial path, what is its energy after the collision with respect to its original energy? What is the final energy of the proton that was originally at rest?

••**7.109** A method for determining the chemical composition of a material is Rutherford backscattering (RBS), named for the scientist who first discovered that an atom contains a high-density positively charged nucleus, rather than having positive charge distributed uniformly throughout (see Chapter 39). In RBS, alpha particles are shot straight at a target material, and the energy of the alpha particles that bounce directly back is measured. An alpha particle has a mass of $6.65 \cdot 10^{-27}$ kg. An alpha particle having an initial kinetic energy of 2.00 MeV

collides elastically with atom X. If the backscattered alpha particle's kinetic energy is 1.59 MeV, what is the mass of atom X? Assume that atom X is initially at rest. You will need to find the square root of an expression, which will result in two possible answers (if $a = b^2$, then $b = \pm\sqrt{a}$). Since you know that atom X is more massive than the alpha particle, you can choose the correct root accordingly. What element is atom X? (Check a periodic table of elements, where atomic mass is listed as the mass in grams of 1 mol of atoms, which is $6.02 \cdot 10^{23}$ atoms.)

MULTI-VERSION EXERCISES

7.110 A Super Ball has a coefficient of restitution of 0.8887. If the ball is dropped from a height of 3.853 m above the floor, what maximum height will it reach on its third bounce?

7.111 A Super Ball has a coefficient of restitution of 0.9115. From what height should the ball be dropped so that its maximum height on its third bounce is 2.234 m?

7.112 A Super Ball is dropped from a height of 3.935 m. Its maximum height on its third bounce is 2.621 m. What is the coefficient of restitution of the ball?

7.113 Two gliders are moving on a horizontal frictionless air track. Glider 1 has mass $m_1 = 160.1$g and is moving to the right (positive x-direction) with a speed of 2.723 m/s. Glider 2 has mass $m_1 = 160.1$ g and is moving to the left (negative x-direction) with a speed of 3.515 m/s. The gliders undergo a totally elastic collision. What is the velocity of glider 1 after the collision?

7.114 Two gliders are moving on a horizontal frictionless air track. Glider 1 has mass $m_1 = 176.3$ g and is moving to the right (positive x-direction) with a speed of 2.199 m/s. Glider 2 is moving to the left (negative x-direction) with a speed of 3.301 m/s. The gliders undergo a totally elastic collision. The velocity of glider 1 after the collision is −4.511 m/s. What is the mass of glider 2?

7.115 Two gliders are moving on a horizontal frictionless air track. Glider 1 is moving to the right (positive x-direction) with a speed of 2.277 m/s. Glider 2 has mass $m_2 = 354.1$ g and is moving to the left (negative x-direction) with a speed of 3.789 m/s. The gliders undergo a totally elastic collision. The velocity of glider 1 after the collision is −4.887 m/s. What is the mass of glider 1?

7.116 A racquetball of mass 41.05 g has a speed of 15.49 m/s and collides with the wall of the court at an angle of 43.53° relative to the normal to the wall. The coefficient of restitution of the racquetball is 0.8199. What is the angle relative to the normal at which the ball leaves the wall?

7.117 A racquetball of mass 41.97 g has a speed of 15.69 m/s and collides with the wall of the court at an angle of 48.67° relative to the normal to the wall. The racquetball leaves the wall at an angle of 55.75° relative to the normal to the wall. What is the coefficient of restitution of the ball?

7.118 A racquetball of mass 38.87 g has a speed of 15.89 m/s and collides with the wall of the court. The ball leaves the wall at an angle of 57.24° relative to the normal to the wall. The coefficient of restitution of the racquetball is 0.8787. What is the initial angle relative to the normal to the wall at which the ball hits the wall?

7.119 A 48.95-kg boy is playing rollerblade dodgeball. His rollerblades are frictionless, and he is initially at rest. A dodgeball with a mass of 511.1 g is thrown directly at him with a speed of 23.63 m/s. He catches the dodgeball. With what speed does the boy move after the catch?

7.120 A 53.53-kg boy is playing rollerblade dodgeball. His rollerblades are frictionless, and he is initially at rest. A dodgeball with a mass of 513.1 g is thrown directly at him, and he catches it. After catching the ball, the boy moves with a speed of 0.2304 m/s. With what speed was the dodgeball thrown?

7.121 A boy is playing rollerblade dodgeball. His rollerblades are frictionless, and he is initially at rest. A dodgeball with a mass of 515.1 g is thrown directly at him with a speed of 24.91 m/s. He catches the dodgeball and then moves with a speed of 0.2188 m/s. What is the mass of the boy?

The International Space Station (ISS), shown in Figure 8.1, is a remarkable engineering achievement. It has been continuously inhabited since 2000. It orbits Earth at a speed of over 7.5 km/s, in an orbit ranging from 320 to 350 km above Earth's surface. When engineers track the ISS, they treat it as a point particle, even though it measures roughly 109 m by 73 m by 25 m. Presumably this point represents the center of the ISS, but how exactly do engineers determine where the center is?

FIGURE 8.1 The International Space Station photographed by Expedition 56 crew members from a Soyuz spacecraft in 2018.

NASA/Roscosmos

Every object has a point where all the mass of the object can be considered to be concentrated. Sometimes this point, called the *center of mass*, is not even within the object. This chapter explains how to calculate the location of the center of mass and shows how to use it to simplify calculations involving conservation of momentum. We have been assuming in earlier chapters that objects could be treated as particles. This chapter shows why that assumption works.

This chapter also discusses changes in momentum for the situation where an object's mass varies as well as its velocity. This occurs with rocket propulsion, where the mass of fuel is often much greater than the mass of the rocket itself.

WHAT WE WILL LEARN

- The center of mass is the point at which we can imagine all the mass of an object to be concentrated.
- The position of the combined center of mass of two or more objects is found by taking the sum of their position vectors, weighted by their individual masses.
- The translational motion of the center of mass of an extended object can be described by Newtonian mechanics.
- The center-of-mass momentum is the sum of the linear momentum vectors of the parts of a system. Its time derivative is equal to the total net external force acting on the system, an extended formulation of Newton's Second Law.
- Analyses of rocket motion have to consider systems of varying mass. This variation leads to a logarithmic dependence of the velocity of the rocket on the ratio of initial to final mass.
- It is possible to calculate the location of the center of mass of an extended object by integrating its mass density over its entire volume, weighted by the coordinate vector, and then dividing by the total mass.
- If an object has a plane of symmetry, the center of mass lies in that plane. If the object has more than one symmetry plane, the center of mass lies on the line or point of intersection of the planes.

8.1 Center of Mass and Center of Gravity

So far, we have represented the location of an object by coordinates of a single point. However, a statement such as "a car is located at $x = 3.2\,\text{m}$" surely does not mean that the entire car is located at that point. So, what does it mean to give the coordinate of one particular point to represent an extended object? Answers to this question depend on the particular application. In auto racing, for example, a car's location is represented by the coordinate of the front most part of the car. When this point crosses the finish line, the race is decided. On the other hand, in soccer, a goal is counted only if the entire ball has crossed the goal line; in this case, it makes sense to represent the soccer ball's location by the coordinates of the rearmost part of the ball. However, these examples are exceptions. In almost all situations, there is a natural choice of a point to represent the location of an extended object. This point is called the *center of mass*, and it is the point at which we can imagine all the mass of an object to be concentrated.

Thus, the center of mass is also the point at which we can imagine the force of gravity acting on the entire object to be concentrated. If we can imagine all of the mass to be concentrated at this point when calculating the force due to gravity, it is legitimate to call this point the *center of gravity*, a term that can often be used interchangeably with *center of mass*. (To be precise, we should note that these two terms are only equivalent in situations where the gravitational force is constant everywhere throughout the object. In Chapter 12, we will see that this is not the case for very large objects.)

It is appropriate to mention here that if an object's mass density is constant, the center of mass (center of gravity) is located in the geometrical center of the object. Thus, for most objects in everyday experience, it is a reasonable first guess that the center of gravity is the middle of the object. The derivations in this chapter will bear out this conjecture.

Combined Center of Mass for Two Objects

If we have two identical objects of equal mass and want to find the center of mass for the combination of the two, it is reasonable to assume from considerations of symmetry that the combined center of mass of this system lies exactly midway between the individual centers of mass of the two objects. If one of the two objects is more massive, then it is equally reasonable to assume that the center of mass for the combination is closer to that of the more massive one. Thus, we have a general formula for calculating the location of the center of mass, $\vec{R}$, for two masses, m_1 and m_2, located at positions $\vec{r}_1$ and $\vec{r}_2$ in an arbitrary coordinate system (Figure 8.2):

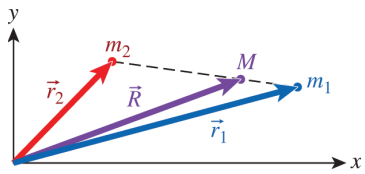

FIGURE 8.2
Location of the center of mass for a system of two masses, m_1 and m_2, where $M = m_1 + m_2$.

$$\vec{R} = \frac{\vec{r}_1 m_1 + \vec{r}_2 m_2}{m_1 + m_2}. \qquad (8.1)$$

This equation says that the center-of-mass position vector is an average of the position vectors of the individual objects, weighted by their mass. Such a definition is consistent with the empirical evidence we have just cited. For now, we will use this equation as an

operating definition and gradually work out its consequences. Later in this chapter and in the following chapters, we will see additional reasons why this definition makes sense.

Concept Check 8.1

In the case shown in Figure 8.2, what are the relative magnitudes of the two masses m_1 and m_2?

a) $m_1 < m_2$

b) $m_1 > m_2$

c) $m_1 = m_2$

d) Based solely on the information given in the figure, it is not possible to decide which of the two masses is larger.

Note that we can immediately write vector equation 8.1 in Cartesian coordinates as follows:

$$X = \frac{x_1 m_1 + x_2 m_2}{m_1 + m_2}, \quad Y = \frac{y_1 m_1 + y_2 m_2}{m_1 + m_2}, \quad Z = \frac{z_1 m_1 + z}{m_1 + r}$$

In Figure 8.2, the location of the center of mass lies exactly on the straight (dashed black) line that connects the two masses. Is this a general result—does the center of mass always lie on this line? If yes, why? If no, what is the special condition that is needed for this to be the case? The answer is that this is a general result for all two-body systems: The center of mass of such a system always lies on the connecting line between the two objects. To see this, we can place the origin of the coordinate system at one of the two masses in Figure 8.2, say m_1. (As we know, we can always shift the origin of a coordinate system without changing the physics results.) Using equation 8.1, we then see that $\vec{R} = \vec{r}_2 m_2/(m_1 + m_2)$, because with this choice of coordinate system, we define $\vec{r}_1$ as zero. Thus, the two

vectors $\vec{R}$ and $\vec{r}_2$ point in the same direction, but $\vec{R}$ is shorter by a factor of $m_2/(m_1 + m_2) < 1$. This shows that $\vec{R}$ always lies on the straight line that connects the two masses.

Concept Check 8.2

A cylindrical bottle of oil-and-vinegar salad dressing whose volume is $1/2$ vinegar (mass density of $1.01\ \text{g/cm}^3$) and $1/2$ oil (mass density of $0.910\ \text{g/cm}^3$) rests on a table. Initially, the oil and the vinegar are separated, with the oil floating on top of the vinegar. The bottle is shaken so that the oil and vinegar mix uniformly and then returned to the table. How has the height of the center of mass of the salad dressing changed as a result of the mixing?

a) It is higher.

b) It is lower.

c) It is the same.

d) There is not enough information to answer this question.

SOLVED PROBLEM 8.1 Center of Mass of Earth and Moon

The Earth has a mass of $5.97 \cdot 10^{24}$ kg, and the Moon has a mass of $7.36 \cdot 10^{22}$ kg. The Moon orbits the Earth at a distance of 384,000 km; that is, the center of the Moon is a distance of 384,000 km from the center of Earth, as shown in Figure 8.3a.

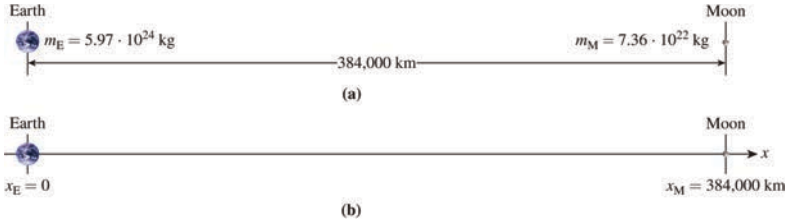

FIGURE 8.3 (a) The Moon orbits the Earth at a distance of 384,000 km (drawing to scale). (b) A sketch showing the Earth at $X_E = 0$ and the Moon at $X_M = 384,000$ km.

PROBLEM

How far from the center of the Earth is the center of mass of the Earth-Moon system?

SOLUTION

THINK

The center of mass of the Earth-Moon system can be calculated by taking the center of the Earth to be located at $x = 0$ and the center of the Moon to be located at $x = 384,000$ km. The center of mass of the Earth-Moon system will lie along a line connecting the center of the Earth and the center of the Moon (as in Figure 8.3a).

SKETCH

A sketch showing Earth and Moon to scale is presented in Figure 8.3b.

RESEARCH

We define an x-axis and place the Earth at $x_{\mathrm{E}} = 0$ and the Moon at $x_{\mathrm{M}} = 384,000\,\mathrm{km}$. We can use equation 8.2 to obtain an expression for the x-coordinate of the center of mass of the Earth-Moon system:

$$X = \frac{x_{\mathrm{E}} m_{\mathrm{E}} + x_{\mathrm{M}} m_{\mathrm{M}}}{m_{\mathrm{E}} + m_{\mathrm{M}}}.$$

SIMPLIFY

Since we have put the origin of our coordinate system at the center of Earth, we set $x_{\mathrm{E}} = 0$. This results in

$$X = \frac{x_{\mathrm{M}} m_{\mathrm{M}}}{m_{\mathrm{E}} + m_{\mathrm{M}}}.$$

CALCULATE

Inserting the numerical values, we get the x-coordinate of the center of mass of the Earth-Moon system:

$$X = \frac{x_{\mathrm{M}} m_{\mathrm{M}}}{m_{\mathrm{E}} + m_{\mathrm{M}}} = \frac{(384,000\,\mathrm{km})\left(7.36 \cdot 10^{22}\,\mathrm{kg}\right)}{5.97 \cdot 10^{24}\,\mathrm{kg} + 7.36 \cdot 10^{22}\,\mathrm{kg}} = 4676.$$

ROUND

All of the numerical values were given to three significant figures, so we report our result as

$$X = 4680\,\mathrm{km}.$$

DOUBLE-CHECK

Our result is in kilometers, which is the correct unit for a position. The center of mass of the Earth-Moon system is close to the center of the Earth. This distance is small compared to the distance between the Earth and the Moon, which makes sense

because the mass of the Earth is much larger than the mass of the Moon. In fact, this distance is less than the radius of the Earth, $R_{\mathrm{E}} = 6370\,\mathrm{km}$. Both Earth and Moon actually orbit the common center of mass. Thus, the Earth seems to wobble as the Moon orbits it.

Combined Center of Mass for Several Objects

The definition of the center of mass in equation 8.1 can be generalized to a total of *n* objects with different masses, m_i, located at different positions, $\vec{r_i}$. In this general case,

$$\vec{R} = \frac{\vec{r_1}m_1 + \vec{r_2}m_2 + \cdots + \vec{r_n}m_n}{m_1 + m_2 + \cdots + m_n} = \frac{\sum_{i=1}^{n} \vec{r_i}m_i}{\sum_{i=1}^{n} m_i} = \frac{1}{M}\sum_{i=1}^{n} \vec{r_i}$$

where *M* represents the combined mass of all *n* objects:

$$M = \sum_{i=1}^{n} m_i. \tag{8.4}$$

Writing equation 8.3 in Cartesian components, we obtain

$$X = \frac{1}{M}\sum_{i=1}^{n} x_i m_i, \quad Y = \frac{1}{M}\sum_{i=1}^{n} y_i m_i, \quad Z = \frac{1}{M}\sum_{i=1}^{n} z_i m_i.$$

The location of the center of mass is a fixed point relative to the object or system of objects and does not depend on the location of the coordinate system used to describe it. We can show this by taking the system of equation 8.3 and moving it by $\vec{r_0}$, resulting in a new center-of-mass position, $\vec{R} + \vec{R_0}$. Using equation 8.3, we find

$$\overrightarrow{R} + \overrightarrow{R}_0 = \frac{\sum_{i=1}^{n} \left(\overrightarrow{r_0} + \overrightarrow{r_i} \right) m_i}{\sum_{i=1}^{n} m_i} = \overrightarrow{r_0} + \frac{1}{M} \sum_{i=1}^{n} \overrightarrow{r_i} m_i.$$

Thus, $\overrightarrow{R}_0 = \overrightarrow{r_0}$, and the location of the center of mass does not change relative to the system.

Now we can determine the center of mass of a collection of objects in the following example.

EXAMPLE 8.1 Shipping Containers

Large freight containers, which can be transported by truck, railroad, or ship, come in standard sizes. One of the most common sizes is the ISO 20′ container, which has a length of 6.1 m, a width of 2.4 m, and a height of 2.6 m. This container is allowed to have a mass (including its contents, of course) of up to 30,400 kg.

PROBLEM

The five freight containers shown in Figure 8.4 sit on the deck of a container ship. Each one has a mass of 9,000 kg, except for the red one, which has a mass of 18,000 kg. Assume that each of the containers has an individual center of mass at its geometric center. What are the x-coordinate and the y-coordinate of the containers' combined center of mass? Use the coordinate system shown in the figure to describe the location of this center of mass.

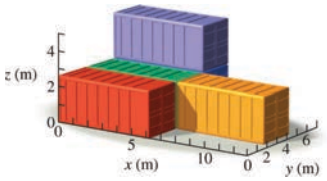

FIGURE 8.4
Freight containers arranged on the deck of a container ship.

SOLUTION

We need to calculate the individual Cartesian components of the center of mass, so we'll use equation 8.5. There does not seem to be a shortcut we can utilize.

Let's call the length of each container ℓ (6.1 m), the width of each container w (2.4 m), and the mass of the green container m_0 (9,000 kg). The mass of the red container is then $2m_0$, and all the others also have a mass of m_0.

First, we need to calculate the combined mass, M. According to equation 8.4, it is

$$\begin{aligned} M &= m_{\text{red}} + m_{\text{green}} + m_{\text{orange}} + m_{\text{blue}} + m_{\text{purple}} \\ &= 2m_0 + m_0 + m_0 + m_0 + m_0 \\ &= 6m_0. \end{aligned}$$

For the x-coordinate of the combined center of mass, we find

$$\begin{aligned} X &= \frac{x_{\text{red}}m_{\text{red}} + x_{\text{green}}m_{\text{green}} + x_{\text{orange}}m_{\text{orange}} + x_{\text{blue}}m}{M} \\ &= \frac{\frac{1}{2}\ell 2m_0 + \frac{1}{2}\ell m_0 + \frac{3}{2}\ell m_0 + \frac{1}{2}\ell m_0 + \frac{1}{2}\ell m_0}{6m_0} \\ &= \frac{\ell\left(1 + \frac{1}{2} + \frac{3}{2} + \frac{1}{2} + \frac{1}{2}\right)}{6} \\ &= \frac{2}{3}\ell = 4.1\,\text{m}. \end{aligned}$$

In the last step, we substituted the value of 6.1 m for ℓ.

In the same way, we can calculate the y-coordinate:

$$\begin{aligned} Y &= \frac{y_{\text{red}}m_{\text{red}} + y_{\text{green}}m_{\text{green}} + y_{\text{orange}}m_{\text{orange}} + y_{\text{blue}}m_{\text{b}}}{M} \\ &= \frac{\frac{1}{2}w 2m_0 + \frac{3}{2}wm_0 + \frac{3}{2}wm_0 + \frac{5}{2}wm_0 + \frac{5}{2}wm_0}{6m_0} \\ &= \frac{w\left(1 + \frac{3}{2} + \frac{3}{2} + \frac{5}{2} + \frac{5}{2}\right)}{6} \\ &= \frac{3}{2}w = 3.6\,\text{m}. \end{aligned}$$

Here again we substituted the numerical value of 2.4 m in the last step. (Note that we rounded both center-of-mass coordinates to two significant figures to be consistent with the given values.)

Self-Test Opportunity 8.1

Determine the *z*-coordinate of the center of mass of the container arrangement in Figure 8.4.

8.2 Center-of-Mass Momentum

Now we can take the time derivative of the position vector of the center of mass to get $\vec{V}$, the velocity vector of the center of mass. We take the time derivative of equation 8.3:

$$\vec{V} \equiv \frac{d}{dt}\vec{R} = \frac{d}{dt}\left(\frac{1}{M}\sum_{i=1}^{n}\vec{r}_i m_i\right) = \frac{1}{M}\sum_{i=1}^{n} m_i \frac{d}{dt}\vec{r}_i = \frac{1}{M}$$

For now, we have assumed that the total mass, M, and the masses, m_i, of the individual objects remain constant. (Later in this chapter, we will give up this assumption and study the consequences for rocket motion.) Equation 8.6 is an expression for the velocity vector of the center of mass, $\vec{V}$. Multiplication of both sides of equation 8.6 by M yields

$$\vec{P} = M\vec{V} = \sum_{i=1}^{n}\vec{p}_i. \qquad \textbf{(8.7)}$$

We thus find that the center-of-mass momentum, $\vec{P}$, is the product of the total mass, M, and the center-of-mass velocity, $\vec{V}$, and is the sum of all the individual momentum vectors.

Taking the time derivative of both sides of equation 8.7 yields Newton's Second Law for the center of mass:

$$\frac{d}{dt}\vec{P} = \frac{d}{dt}\left(M\vec{V}\right) = \frac{d}{dt}\left(\sum_{i=1}^{n}\vec{p_i}\right) = \sum_{i=1}^{n}\frac{d}{dt}\vec{p_i} = \sum_{i=1}^{n}$$

In the last step, we used the result from Chapter 7 that the time derivative of the momentum of particle i is equal to the net force, $\vec{F_i}$, acting on it. Note that if the particles (objects) in a system exert forces on one another, those forces do not make a net contribution to the sum of forces in equation 8.8. Why? According to Newton's Third Law, the forces that two objects exert on each other are equal in magnitude and opposite in direction. Therefore, adding them yields zero. Thus, we obtain Newton's Second Law for the center of mass:

$$\frac{d}{dt}\vec{P} = \vec{F}_{\text{net}}, \qquad \textbf{(8.9)}$$

where $\vec{F}_{\text{net}}$ is the sum of all *external forces* acting on the system of particles.

The center of mass has the same relationships among position, velocity, momentum, force, and mass that have been established for point particles. It is thus possible to consider the center of mass of an extended object or a group of objects as a point particle. This conclusion justifies the approximation we used in earlier chapters of representing objects as points.

Recoil

When a bullet is fired from a gun, the gun **recoils;** that is, it moves in the direction opposite to that in which the bullet is fired. Another demonstration of the same physical principle occurs if you are sitting in a boat that is at rest and you throw an object off the boat: The boat moves in the direction opposite from that of the object. You also experience the same effect if you stand on a skateboard and toss a (reasonably heavy) ball. This well-known recoil effect is a consequence of Newton's Third Law.

SOLVED PROBLEM 8.2 Cannon Recoil

Suppose a cannonball of mass 13.7 kg is fired at a target that is 2.30 km away from the cannon, which has a mass of 249.0 kg. The distance 2.30 km is also the maximum range of the cannon. The target and cannon are at the same elevation, and the cannon is resting on a horizontal surface.

PROBLEM

What is the velocity with which the cannon will recoil?

SOLUTION

THINK

First, we realize that the cannon can recoil only in the horizontal direction, because the normal force exerted by the ground will prevent it from acquiring a downward velocity component. We use the fact that the x-component of the center-of-mass momentum of the system (cannon and cannonball) remains unchanged in the process of firing the cannon, because the explosion of the gunpowder inside the cannon, which sets the cannonball in motion, creates only forces internal to the system. No net external force component occurs in the horizontal direction because the two external forces (normal force and gravity) are both vertical. The y-component of the center-of-mass velocity changes because a net external force component does occur in the y-direction when the normal force increases to prevent the cannon from penetrating the ground. Because the cannonball and cannon are both initially at rest, the center-of-mass momentum of this system is initially zero, and its x-component remains zero after the firing of the cannon.

SKETCH

Figure 8.5a is a sketch of the cannon just as the cannonball is fired. Figure 8.5b shows the velocity vector of the cannonball, $\vec{v}_2$, including the x- and y-components.

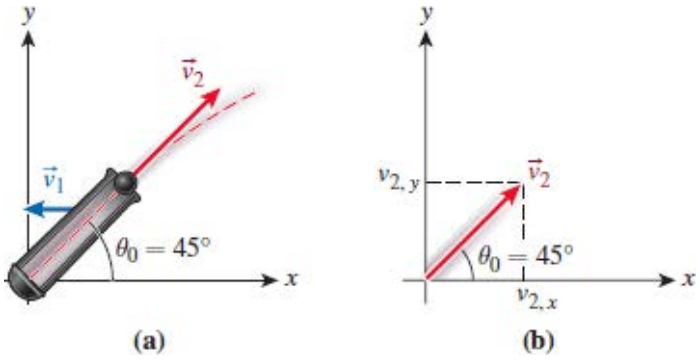

FIGURE 8.5 (a) Cannonball being fired from a cannon. (b) The initial velocity vector of the cannonball.

RESEARCH

Using equation 8.7 with index 1 for the cannon and index 2 for the cannonball, we obtain

$$\vec{P} = \vec{p}_1 + \vec{p}_2 = m_1\vec{v}_1 + m_2\vec{v}_2 = 0 \Rightarrow \vec{v}_1 = -\frac{m_2}{m_1}\vec{v}_2.$$

For the horizontal component of the velocity, we then have

$$v_{1,x} = -\frac{m_2}{m_1}v_{2,x}. \qquad \text{(i)}$$

We can obtain the horizontal component of the cannonball's initial velocity (at firing) from the fact that the range of the cannon is 2.30 km. In Chapter 3, we saw that the range of the cannon is related to the initial velocity via $R = \left(v_0^2/g\right)(\sin 2\theta_0)$. The maximum range is reached for $\theta_0 = 45^\circ$ and is $R = v_0^2/g \Rightarrow v_0 = \sqrt{gR}$. For $\theta_0 = 45^\circ$, the initial speed and horizontal velocity component are related via $v_{2,x} = v_0 \cos 45^\circ = v_0/\sqrt{2}$. Combining these two results, we can relate the maximum range to the horizontal component of the initial velocity of the cannonball:

$$v_{2,x} = \frac{v_0}{\sqrt{2}} = \sqrt{\frac{gR}{2}}. \qquad \text{(ii)}$$

SIMPLIFY

Substituting from equation (ii) into equation (i) gives us the result we are looking for

$$v_{1,x} = -\frac{m_2}{m_1} v_{2,x} = -\frac{m_2}{m_1}\sqrt{\frac{gR}{2}}.$$

CALCULATE

Inserting the numbers given in the problem statement, we obtain

$$v_{1,x} = -\frac{m_2}{m_1}\sqrt{\frac{gR}{2}} = -\frac{13.7\,\text{kg}}{249\,\text{kg}}\sqrt{\frac{(9.81\,\text{m/s}^2)(2.30\cdot 10^3\,\text{m}}{2}}$$

ROUND

Expressing our answer to three significant figures gives

$$v_{1,x} = -5.84\,\text{m/s}.$$

DOUBLE-CHECK

The minus sign means that the cannon moves in the opposite direction to that of the cannonball, which is reasonable. The cannonball should have a much larger initial velocity than the cannon because the cannon is much more massive. The initial velocity of the cannonball was

$$v_0 = \sqrt{gR} = \sqrt{(9.81\,\text{m/s}^2)(2.3\cdot 10^3\,\text{m})} = 150\,\text{m/s}.$$

The fact that our answer for the velocity of the cannon is much less than the initial velocity of the cannonball also seems reasonable.

Mass can be ejected continuously from a system, producing a continuous recoil. As an example, let's consider the spraying of water from a fire hose.

EXAMPLE 8.2 Fire Hose

PROBLEM

What is the magnitude of the force, F, that acts on a firefighter holding a fire hose that has a diameter $D_1 = 5.00$ cm that ejects 360. L of water per minute with a muzzle speed of $v_2 = 39.0$ m/s through an opening in the nozzle with a diameter $D_2 = 2.50$ cm, as shown in Figure 8.6?

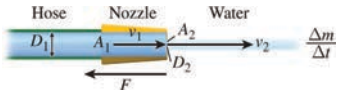

FIGURE 8.6 A fire hose with water leaving at speed v_2.

McGraw Hill

SOLUTION

We might be tempted to treat this situation as if the recoil of the fire hose is due to the momentum of the water moving out of the nozzle of the fire hose. However, in this case, the force on the water in the fire hose occurs back at the pump in the fire truck, not at the nozzle. Instead, we will calculate the recoil of the fire hose due to the change in momentum of the water as it exits the nozzle.

Let's first find the total mass of the water that is being ejected per minute. The mass density of water is $\rho = 1000.\ \text{kg/m}^3 = 1.000\ \text{kg/L}$. Because $\Delta V = 360.\ \text{L}$, we get for the total mass of water ejected in a minute:

$$\Delta m = \Delta V_\rho = (360.\ \text{L})(1.000\ \text{kg/L}) = 360.\ \text{kg}.$$

The mass of water per unit time is then

$$\frac{\Delta m}{\Delta t} = \frac{360.\ \text{kg}}{60.0\ \text{s}} = 6.00\ \text{kg/s}.$$

The cross-sectional area of the hose is

$$A_1 = \pi\left(\frac{D_1}{2}\right)^2 = \pi\left(\frac{0.0500\text{ m}}{2}\right)^2 = 1.96 \cdot 10^{-3}\text{ m}^2.$$

The cross-sectional area of the exit of the nozzle is

$$A_2 = \pi\left(\frac{D_2}{2}\right)^2 = \pi\left(\frac{0.0250\text{ m}}{2}\right)^2 = 4.91 \cdot 10^{-4}\text{ m}^2.$$

The water is traveling in the hose with speed v_1 and is ejected from the nozzle with speed $v_2 = 239.0\text{ m/s}$. After the water passes through the restricted opening of the nozzle, it will be moving at a faster speed. This effect is governed by the equation of continuity given by

$$v_1 A_1 = v_2 A_2.$$

We will learn more about this phenomenon in Chapter 13 when we study fluids in motion. The change in the momentum of the water is then $\Delta p = \Delta m(v_2 - v_1)$ and from the definition of the average force, $F = \Delta p/\Delta t$, we have

$$F = \frac{\Delta p}{\Delta t} = \frac{\Delta m}{\Delta t}(v_2 - v_1) = \frac{\Delta m}{\Delta t}\left(v_2 - v_2\frac{A_2}{A_1}\right) = v_2\frac{\Delta n}{\Delta t}$$

$$F = (39.0\text{ m/s})(6.00\text{ kg})\left(1 - \frac{4.91 \cdot 10^{-4}\text{ m}^2}{1.96 \cdot 10^{-3}\text{ m}^2}\right) = 176\text{ N}.$$

This force is sizable, which is why it is dangerous for firefighters to let go of operating fire hoses: They could whip around, potentially causing injury.

Concept Check 8.3

The fire hose of Example 8.2 is used to spray firefighting foam (with a mass density half that of water) at the same flow rate of $360.\ \mathrm{L/min}$ and at the same muzzle speed of $39.0\ \mathrm{m/s}$. The force acting on a firefighter holding the hose in this case is

a) four times the force found in Example 8.2.

b) twice the force found in Example 8.2.

c) the same as the force found in Example 8.2.

d) half the force found in Example 8.2.

e) a quarter of the force found in Example 8.2.

General Motion of the Center of Mass

Extended solid objects can have motions that appear, at first sight, rather complicated. One example of such motion is high jumping. During the 1968 Olympic Games in Mexico City, the American track-and-field star Dick Fosbury won a gold medal using a new high-jump technique, which became known as the Fosbury flop (see Figure 8.7). Properly executed, the technique allows the athlete to cross over the bar while his or her center of mass remains below it, thus adding effective height to the jump.

FIGURE 8.7 Dick Fosbury clears the high-jump bar during the finals of the Olympic Games in Mexico City on October 20, 1968.

AP Images

Figure 8.8a shows a wrench twirling through the air, in a multiple-exposure series of images with equal time intervals between sequential frames. While this motion looks complicated, we can use what we know about the center of mass to perform a straightforward analysis of this motion. If we assume that all the mass of the wrench is concentrated at a point, then this point will move on a parabola through the air under the influence of gravity, as discussed in Chapter 3. Superimposed on this motion is a rotation of the wrench about its center of mass. You can see this parabolic trajectory clearly in Figure 8.8b, where a superimposed parabola (green) passes

through the location of the center of mass of the wrench in each exposure. In addition, a superimposed black line rotates with a constant rate about the center of mass of the wrench. You can clearly see that the handle of the wrench is always aligned with the black line, indicating that the wrench rotates with constant rate about its center of mass (we will analyze such rotational motion in Chapter 10).

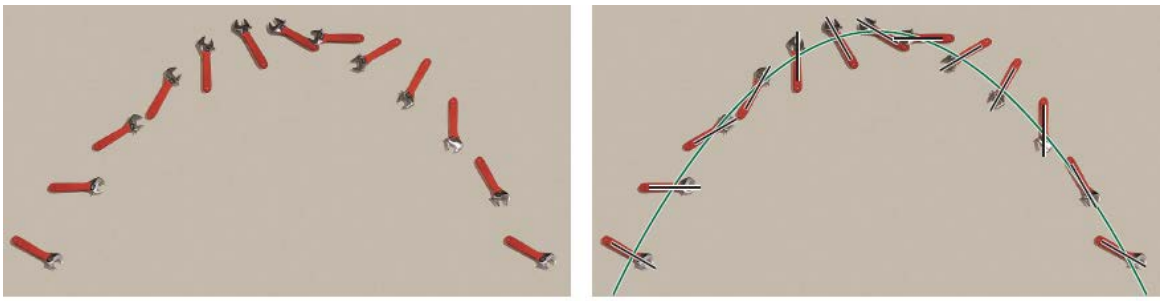

FIGURE 8.8 (a) Digitally processed multiple-exposure series of images of a wrench tossed through the air. (b) Same series as in part (a), but with a parabola for the center-of-mass motion superimposed.

a-b: W. Bauer and G. D. Westfall

The techniques introduced here allow us to analyze many kinds of complicated problems involving moving solid objects in terms of superposition of the motion of the center of mass and a rotation of the object about the center of mass.

8.3 Rocket Motion

Example 8.2 about the fire hose is the first situation we have examined that involves a change in momentum due to a change in mass rather than in velocity. Another important situation in which changing momentum is due to changing mass is rocket motion, where part of the mass of the rocket is ejected through a nozzle or nozzles at the rear (Figure 8.9). Rocket motion is an important case of the recoil effect discussed in Section 8.2. A rocket does not "push against" anything. Instead, its forward thrust is gained from ejecting its propellant from its rear, according to the law of conservation of total momentum.

FIGURE 8.9 A Delta II rocket lifting a GPS satellite into orbit.

Kim Shiflett/NASA

In order to obtain an expression for the acceleration of a rocket, we'll first consider ejecting discrete amounts of mass out of the rocket. Then we can approach the continuum limit. Let's use a toy model of a rocket that moves in interstellar space, propelling itself forward by shooting cannonballs out its back end (Figure 8.10). (We specify that the rocket is in interstellar space so we can treat it and its components as an isolated system, for which we can neglect outside forces.) Initially, the rocket is at rest. All motion is in the x-direction,

so we can use notation for one-dimensional motion, with the signs of the x-components of the velocities (which, for simplicity, we will refer to as velocities) indicating their direction. Each cannonball has a mass of Δm, and the initial mass of the rocket, including all cannonballs, is m_0. Each cannonball is fired with a speed of v_c relative to the common center of mass of the rocket and the cannonballs, resulting in a cannonball momentum of $v_c \Delta m$.

FIGURE 8.10 Toy model for rocket propulsion: firing cannonballs.

After the first cannonball is fired, the mass of the rocket is reduced to $m_0 - \Delta m$. Firing the cannonball does not change the center-of-mass momentum of the system (rocket plus cannonball). (Remember, this is an isolated system, on which no net external forces act.) Thus, the rocket receives a recoil momentum opposite to that of the cannonball. The momentum of the cannonball is

$$p_c = v_c \Delta m, \tag{8.10}$$

and the momentum of the rocket is

$$p_r = (m_0 - \Delta m) v_1,$$

where v_1 is the velocity of the rocket after the cannonball is fired. Because momentum is conserved, we can write $p_r + p_c = 0$, and then substitute p_r and p_c from the preceding two expressions:

$$(m_0 - \Delta m) v_1 + v_c \Delta m = 0.$$

We define the change in the velocity, Δv_1, of the rocket after firing one cannonball by

$$v_1 = v_0 + \Delta v = 0 + \Delta v = \Delta v_1, \tag{8.11}$$

where the assumption that the rocket was initially at rest means $v_0 = 0$. This gives us the recoil velocity of the rocket due to the firing of one cannonball:

$$\Delta v_1 = -\frac{v_c \Delta m}{m_0 - \Delta m}. \tag{8.12}$$

In the moving system of the rocket, we can then fire the second cannonball. Firing the second cannonball reduces the mass of the rocket from $m_0 - \Delta m$ to $m_0 - 2\Delta m$, which results in an additional recoil velocity of

$$\Delta v_2 = -\frac{v_c \Delta m}{m_0 - 2\Delta m}.$$

The total velocity of the rocket then increases to $v_2 = v_1 + \Delta v_2$. After firing the *n*th cannonball, the velocity change is

$$\Delta v_n = -\frac{v_c \Delta m}{m_0 - n\Delta m}. \tag{8.13}$$

Thus, the velocity of the rocket after firing the *n*th cannonball is

$$v_n = v_{n-1} + \Delta v_n.$$

This kind of equation, which defined the *n*th term of a sequence where each term is expressed as a function of the preceding terms, is called a *recursion relation*. It can be solved in a straightforward manner by using a computer. However, we can use a very helpful approximation for the case where the mass emitted per unit time is constant and small compared to m, the overall (time-dependent) mass of the rocket. In this limit, we obtain from equation 8.13

$$\Delta v = -\frac{v_c \Delta m}{m} \Rightarrow \frac{\Delta v}{\Delta m} = -\frac{v_c}{m}. \tag{8.14}$$

Here v_c is the speed with which the cannonball is ejected. In the limit $\Delta m \to 0$, we then obtain the derivative

$$\frac{dv}{dm} = -\frac{v_c}{m}. \tag{8.15}$$

The solution of this differential equation is

$$v(m) = -v_c \int_{m_0}^{m} \frac{1}{m'} dm' = -v_c \ln m' \Big|_{m_0}^{m} = v_c \ln\left(\frac{m_0}{m}\right). \text{(8.}$$

(You can verify that equation 8.16 is indeed the solution of equation 8.15 by taking the derivative of equation 8.16 with respect to m.)

If m_i is the initial value for the total mass at some time t_i and m_f is the final mass at a later time, we can use equation 8.16 to obtain $v_i = v_c \ln(m_0/m_i)$ and $v_f = v_c \ln(m_0/m_f)$ for the initial and final velocities of the rocket. Then, using the property of logarithms, $\ln(a/b) = \ln a - \ln b$, we find the difference in those two velocities:

$$v_f - v_i = v_c \ln\left(\frac{m_0}{m_f}\right) - v_c \ln\left(\frac{m_0}{m_i}\right) = v_c \ln\left(\frac{m_i}{m_f}\right). \text{(8.17}$$

EXAMPLE 8.3 Rocket Launch to Mars

One proposed scheme for sending astronauts to Mars involves assembling a spaceship in orbit around Earth, thus avoiding the need for the spaceship to overcome most of Earth's gravity at the start. Suppose such a spaceship has a payload of 50,000 kg, carries 2,000,000 kg of fuel, and is able to eject the propellant with a speed of 23.5 km/s. (Current chemical rocket propellants yield a maximum speed of approximately 5 km/s, but electromagnetic rocket propulsion is predicted to yield a speed of perhaps 40 km/s.)

PROBLEM

What is the final speed that this spaceship can reach, relative to the velocity it initially had in its orbit around Earth?

SOLUTION

Using equation 8.17 and substituting the numbers given in this problem, we find

$$v_f - v_i = v_c \ln\left(\frac{m_i}{m_f}\right) = (23.5\ \text{km/s}) \ln\left(\frac{2{,}050{,}000\ \text{kg}}{50{,}000\ \text{kg}}\right) =$$

For comparison, the Saturn V multistage rocket that carried astronauts to the Moon in the late 1960s and early 1970s was able to reach a speed of only about 12 km/s.

However, even with advanced technology such as electromagnetic propulsion, it would still take several months for astronauts to reach Mars, even under the most favorable conditions. The *Mars Rover*, for example, took 207 days to travel from Earth to Mars. NASA estimates that astronauts on such a mission would receive approximately 10 to 20 times more radiation than the maximum allowable annual dose for radiation workers, leading to high probabilities of developing cancer and brain damage. No shielding mechanism has yet been proposed that could protect the astronauts from this danger.

Concept Check 8.4

If the payload of the spaceship in Example 8.3 is doubled, from 50,000 kg to 100,000 kg, the final speed the spaceship can reach will be

a) the same as the speed found in Example 8.3.

b) a bit lower than the speed found in Example 8.3 but more than half that speed.

c) a bit higher than the speed found in Example 8.3.

d) half of the speed found in Example 8.3.

e) less than half of the speed found in Example 8.3.

Another and perhaps easier way to think of rocket motion is to go back to the definition of momentum as the product of mass and velocity and take the time derivative to obtain the force. However, now the mass of the object can change as well:

$$\vec{F}_{\text{net}} = \frac{d}{dt}\vec{p} = \frac{d}{dt}\left(m\vec{v}\right) = m\frac{d\vec{v}}{dt} + \vec{v}\frac{dm}{dt}.$$

(The last step in this equation represents the application of the product rule of differentiation from calculus.) If no external force is acting on an object $\left(\vec{F}_{\text{net}} = 0\right)$, then we obtain

$$m\frac{d\vec{v}}{dt} = -\vec{v}\frac{dm}{dt}.$$

In the case of rocket motion (as illustrated in Figure 8.11), the outflow of propellant, dm/dt, is constant and creates the change in

mass of the rocket. The propellant moves with a constant velocity, $\vec{v}_c$, relative to the rocket, so we obtain

FIGURE 8.11 Rocket motion.

$$m\frac{d\vec{v}}{dt} = m\vec{a} = -\vec{v}_c\frac{dm}{dt}.$$

The combination $v_c(dm/dt)$ is called the **thrust** of the rocket. It is a force and thus is measured in newtons:

$$\vec{F}_{\text{thrust}} = -\vec{v}_c\frac{dm}{dt}. \tag{8.18}$$

The thrust generated by space shuttle rocket engines and boosters was approximately 30.4 MN (30.4 meganewtons, or approximately 7.0 million pounds). The initial total mass of a space shuttle, including payload, fuel tanks, and rocket fuel, was slightly greater than 2.0 million kg; thus, the shuttle's rocket engines and boosters were able to produce an initial acceleration of

$$a = \frac{F_{\text{net}}}{m} = \frac{3.04 \cdot 10^7\ \text{N}}{2.0 \cdot 10^6\ \text{kg}} = 15\ \text{m/s}^2.$$

This acceleration is sufficient to lift the shuttle off the launch pad against the acceleration of gravity $\left(-9.81\ \text{m/s}^2\right)$. Once the shuttle rises and its mass decreases, it can generate a larger acceleration. As the fuel is expended, the main engines are throttled back to make sure that the acceleration does not exceed 3g (three times gravitational acceleration) in order to avoid damaging the cargo or injuring the astronauts.

SOLVED PROBLEM 8.3 Thruster Firing

PROBLEM

Suppose a spacecraft has an initial mass of 1,850,000 kg. Without its propellant, the spacecraft has a mass of 50,000 kg. The rocket that powers the spacecraft is designed to eject the propellant with a speed of 25 km/s with respect to the rocket at a constant rate of 15, 000 kg/s The spacecraft is initially at rest in space and travels in a straight line. How far will the spacecraft travel before its rocket uses all the propellant and shuts down?

SOLUTION

THINK

The total mass of propellant is the total mass of the spacecraft minus the mass of the spacecraft after all the propellant is ejected. The rocket ejects the propellant at a fixed rate, so we can calculate the amount of time during which the rocket operates. As the propellant is used up, the mass of the spacecraft decreases and the speed of the spacecraft increases. If the spacecraft starts from rest, the speed $v(t)$ at any time while the rocket is operating can be obtained from equation 8.17, with the final mass of the spacecraft replaced by the mass of the spacecraft at that time. The distance traveled before all the propellant is used is given by the integral of the speed as a function of time.

SKETCH

The flight of the spacecraft is sketched in Figure 8.12.

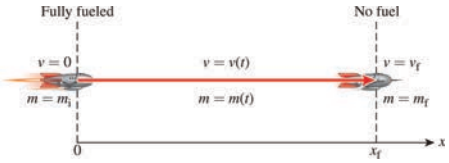

FIGURE 8.12 The various parameters for the spacecraft as the rocket operates.

RESEARCH

We symbolize the rate at which the propellant is ejected by r_{p}. The time $t_{\max}$ during which the rocket will operate is then given by

$$t_{\max} = \frac{(m_{\mathrm{i}} - m_{\mathrm{f}})}{r_{\mathrm{p}}},$$

where m_{i} is the initial mass of the spacecraft and m_{f} is the mass of the spacecraft after all the propellant is ejected. The total distance the spacecraft travels in this time interval is the integral of the speed over time:

$$x_{\mathrm{f}} = \int_0^{t_{\max}} v(t)dt. \qquad \text{(i)}$$

While the rocket is operating, the mass of the spacecraft at a time t is given by

$$m(t) = m_{\mathrm{i}} - r_{\mathrm{p}}t.$$

The speed of the spacecraft at any given time after the rocket starts to operate and before all the propellant is used up is given by (compare to equation 8.17)

$$v(t) = v_c \ln\left(\frac{m_i}{m(t)}\right) = v_c \ln\left(\frac{m_i}{m_i - r_p t}\right) = v_c \ln\left(\frac{}{1 -}\right.$$

where v_c is the speed of the ejected propellant with respect to the rocket.

SIMPLIFY

Now we substitute from equation (ii) for the time dependence of the speed of the spacecraft into equation (i) and obtain

$$x_f = \int_0^{t_{max}} v(t)dt = \int_0^{t_{max}} v_c \ln\left(\frac{1}{1 - r_p t/m_i}\right)dt = -v_c \int_0^{t_{max}}$$

Because $\int \ln(1 - ax)\, dx = \frac{ax - 1}{a}\ln(1 - ax) - x$ (you can look up this result in an integral table), the integral evaluates to

$$\begin{aligned}\int_0^{t_{max}} \ln(1 - r_p t/m_i)dt &= \left[\left(\frac{r_p t/m_i - 1}{r_p/m_i}\right)\ln(1 - r_p t/m_i) - \right. \\ &= \left(\frac{r_p t_{max}/m_i - 1}{r_p/m_i}\right)\ln(1 - r_p t_{max}/ \\ &= (t_{max} - m_i/r_p)\ln(1 - r_p t_{max}/m_i)\end{aligned}$$

The distance traveled is then

$$x_f = -v_c\left[(t_{max} - m_i/r_p)\ln(1 - r_p t_{max}/m_i) - t_{max}\right].$$

CALCULATE

The time during which the rocket is operating is

$$t_{\max} = \frac{m_{\mathrm{i}} - m_{\mathrm{f}}}{r_{\mathrm{p}}} = \frac{1{,}850{,}000\ \mathrm{kg} - 50{,}000\ \mathrm{kg}}{15{,}000\ \mathrm{kg/s}} = 120\ \mathrm{s}.$$

Putting numerical values into the factor $1 - r_{\mathrm{p}} t_{\max}/m_{\mathrm{i}}$ gives

$$1 - \frac{r_{\mathrm{p}} t_{\max}}{m_{\mathrm{i}}} = 1 - \frac{15{,}000\ \mathrm{kg/s} \cdot 120\ \mathrm{s}}{1{,}850{,}000\ \mathrm{kg}} = 0.027027.$$

Thus, we find for the distance traveled

$$\begin{aligned} x_{\mathrm{f}} &= -\left(25 \cdot 10^3\ \mathrm{m/s}\right)\left[-(120\ \mathrm{s}) + \left\{(120\ \mathrm{s}) - \left(1.85 \cdot 10^6\ \mathrm{kg}\right.\right.\right. \\ &= 2.69909 \cdot 10^6\ \mathrm{m}. \end{aligned}$$

ROUND

Because the propellant speed was given to only two significant figures, we need to round to that accuracy:

$$x_{\mathrm{f}} = 2.7 \cdot 10^6\ \mathrm{m}.$$

DOUBLE-CHECK

To double-check our answer for the distance traveled, we use equation 8.17 to calculate the final velocity of the spacecraft:

$$v_{\mathrm{f}} = v_{\mathrm{c}} \ln\left(\frac{m_{\mathrm{i}}}{m_{\mathrm{f}}}\right) = (25\ \mathrm{km/s}) \ln\left(\frac{1.85 \cdot 10^6\ \mathrm{kg}}{5 \cdot 10^4\ \mathrm{kg}}\right) = 90.3\ \mathrm{l}$$

If the spacecraft accelerated at a constant rate, the speed would increase linearly with time, as shown in Figure 8.13, and the average speed during the time the propellant was being ejected would be $\overline{v} = v_{\mathrm{f}}/2$. Taking this average speed and multiplying by that time gives

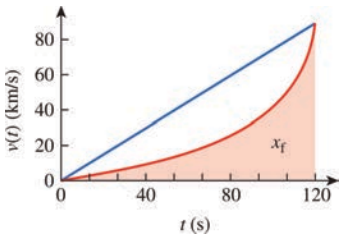

FIGURE 8.13
Comparison of the exact solution for $v(t)$ (red curve) to one for constant acceleration (blue line).

$$x_{a-\text{const}} \approx \bar{v}t_{\text{max}} = (v_f/2)t_{\text{max}} = (90.3\,\text{km/s})(120\,\text{s})/2 = 5.$$

This approximate distance is bigger than our calculated answer, because in the calculation the velocity increases in time until it reaches the value of $90.3\,\text{km/s}$. The approximation is about twice the calculated distance, giving us confidence that our answer at least has the right order of magnitude.

Figure 8.13 shows the exact solution for $v(t)$ (red curve). The distance traveled, x_f, is the area under the red curve. The blue line shows the case where constant acceleration leads to the same final velocity. As you can see, the area under the blue line is approximately twice that under the red curve. Since we just calculated the area under the blue line, $x_{a-\text{const}}$, and found it to be about twice as big as our calculated result, we gain confidence that we interpreted correctly.

8.4 Calculating the Center of Mass

So far, we have not addressed a key question: How do we calculate the location of the center of mass for an arbitrarily shaped object? To answer this question, let's find the location of the center of mass of the hammer shown in Figure 8.14. To do this, we can represent the hammer by small identically sized cubes, as shown in the lower part of the figure. The centers of the cubes are their individual centers of mass, marked with red dots. The red arrows are the position vectors of the cubes. If we accept the collection of cubes as a good approximation for the hammer, we can use equation 8.3 to find the center of mass of the collection of cubes and thus that of the hammer.

FIGURE 8.14
Calculating the center of mass for a hammer.

W. Bauer and G. D. Westfall

Note that not all the cubes have the same mass, because the densities of the wooden handle and the iron head are very different.

The relationship between mass density (ρ), mass, and volume is given by

$$\rho = \frac{dm}{dV}. \tag{8.19}$$

If the mass density is uniform throughout an object, we simply have

$$\rho = \frac{M}{V} (\text{for constant } \rho). \tag{8.20}$$

We can then use the mass density and rewrite equation 8.3:

$$\overrightarrow{R} = \frac{1}{M} \sum_{i=1}^{n} \overrightarrow{r_i} m_i = \frac{1}{M} \sum_{i=1}^{n} \overrightarrow{r_i} \rho\left(\overrightarrow{r_i}\right) V.$$

Here we have assumed that the mass density of each small cube is uniform (but still possibly different from one cube to another) and that each cube has the same (small) volume, *V*.

Concept Check 8.5

If we have an object with variable mass density $\rho\left(\vec{r}\right)$ and center-of-mass coordinate $\vec{R}$ and we replace it with an object of exactly the same shape but with a variable mass density that is twice as high as in the first object at every point, then the new center-of-mass coordinate is

a) $\vec{R}$.

b) $2\vec{R}$.

c) $\vec{R}/2$.

d) any of the above, depending on the shape of the objects.

We can obtain a better and better approximation by shrinking the volume of each cube and using a larger and larger number of cubes. This procedure should look very familiar to you, because it is exactly what is done in calculus to arrive at the limit for an integral. In this limit, we obtain for the location of the center of mass for an arbitrarily shaped object:

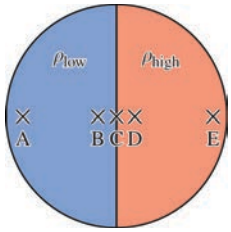
$$\vec{R} = \frac{1}{M}\int_V \vec{r}\rho\left(\vec{r}\right)dV. \qquad \textbf{(8.21)}$$

Here the three-dimensional volume integral extends over the entire volume of the object under consideration.

The next question that arises is what coordinate system to choose in order to evaluate this integral. You may have never seen a three-dimensional integral before and may have worked only with one-dimensional integrals of the form $\int f(x)dx$. However, all three-

dimensional integrals that we will use in this chapter can be reduced to (at most) three successive one-dimensional integrals, most of which are very straightforward to evaluate, provided one selects an appropriate system of coordinates.

Concept Check 8.6



McGraw Hill

The object shown is made of two half circles. The left half is slightly less dense than the right half. Which location best represents the location of the center of mass of the object?

Three-Dimensional Non-Cartesian Coordinate Systems

Chapter 1 introduced a three-dimensional orthogonal coordinate system, the Cartesian coordinate system, with coordinates x, y, and z. However, for some applications, it is mathematically simpler to represent the position vector in another coordinate system. This section briefly introduces two commonly used three-dimensional coordinate systems that can be used to specify a vector in three-dimensional space: spherical coordinates and cylindrical coordinates.

Spherical Coordinates.

In **spherical coordinates,** the position vector $\overrightarrow{r}$ is represented by giving its length, r; its polar angle relative to the positive z-axis, θ; and the azimuthal angle of the vector's projection onto the xy-plane relative to the positive x-axis, ϕ Figure 8.15).

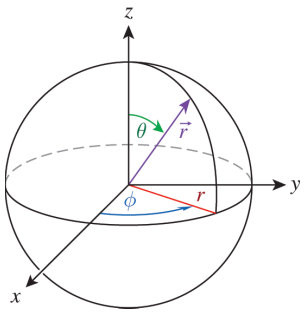


FIGURE 8.15 Three-dimensional spherical coordinate system.

We can obtain the Cartesian coordinates of the vector $\overrightarrow{r}$ from its spherical coordinates via the transformation

$$\begin{aligned} x &= r\ \cos\phi\ \sin\theta \\ y &= r\ \sin\phi\ \sin\theta \\ z &= r\ \cos\theta. \end{aligned} \qquad \textbf{(8.22)}$$

The inverse transformation from Cartesian to spherical coordinates is

$$
\begin{aligned}
r &= \sqrt{x^2 + y^2 + z^2} \\
\theta &= \cos^{-1}\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right) \\
\phi &= \tan^{-1}\left(\frac{y}{x}\right).
\end{aligned}
\tag{8.23}
$$

Cylindrical Coordinates.

Cylindrical coordinates can be thought of as an intermediate between Cartesian and spherical coordinate systems, in the sense that the Cartesian z-coordinate is retained, but the Cartesian coordinates x and y are replaced by the coordinates $r_\perp$ and ϕ (Figure 8.16). Here $r_\perp$ specifies the length of the projection of the position vector $\vec{r}$ onto the xy-plane, so it measures the perpendicular distance to the z-axis. Just as in spherical coordinates, ϕ is the angle of the vector's projection into the xy-plane relative to the positive x-axis.

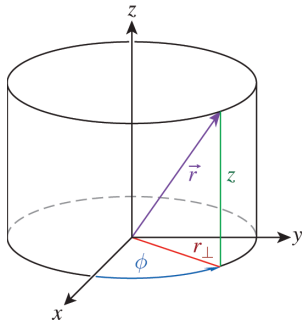

FIGURE 8.16 Cylindrical coordinate system in three dimensions.

We obtain the Cartesian coordinates from the cylindrical coordinates via

$$\begin{aligned} x &= r_\perp \cos\phi \\ y &= r_\perp \sin\phi \\ z &= z. \end{aligned} \qquad \textbf{(8.24)}$$

The inverse transformation from Cartesian to cylindrical coordinates is

$$
\begin{aligned}
r_{\perp} &= \sqrt{x^2 + y^2} \\
\phi &= \tan^{-1}\left(\frac{y}{x}\right) \\
z &= z.
\end{aligned}
\tag{8.25}
$$

As a rule of thumb, you should use a Cartesian coordinate system in your first attempt to describe any physical situation. However, cylindrical and spherical coordinate systems are often preferable when working with objects that have symmetry about a point or a line. Later in this chapter, we will make use of a cylindrical coordinate system to perform a three-dimensional volume integral. Chapter 9 will discuss polar coordinates, which can be thought of as the two-dimensional equivalent of either cylindrical or spherical coordinates. Finally, in Chapter 10, we will again use spherical and cylindrical coordinates to solve slightly more complicated problems requiring integration.

Volume Integrals

Even though calculus is a prerequisite for physics, many universities allow students to take introductory physics and calculus courses concurrently. In general, this approach works well, but when students encounter multidimensional integrals in physics, it is often the first time they have seen this notation. Therefore, let's review the basic procedure for performing these integrations.

If we want to integrate any function over a three-dimensional volume, we need to find an expression for the volume element dV in an appropriate set of coordinates. Unless there is an extremely important reason not to, you should always use orthogonal coordinate systems. The three commonly used three-dimensional orthogonal coordinate systems are the Cartesian, cylindrical, and spherical systems.

It is easiest by far to express the volume element dV in Cartesian coordinates; it is simply the product of the three individual coordinate elements (Figure 8.17). The three-dimensional volume integral written in Cartesian coordinates is

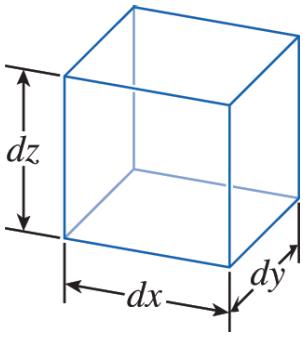

FIGURE 8.17 Volume element in Cartesian coordinates.

$$\int_V f(\vec{r})\,dV = \int_{z_{\min}}^{z_{\max}} \left(\int_{y_{\min}}^{y_{\max}} \left(\int_{x_{\min}}^{x_{\max}} f(\vec{r})\,dx \right) dy \right) dz. \quad \textbf{(8.26)}$$

In this equation, $f\left(\vec{r}\right)$ can be an arbitrary function of the position. The lower and upper boundaries for the individual coordinates are denoted by $x_{\min}, x_{\max}, \ldots$. The convention is to solve the innermost integral first and then work outward. For equation 8.26, this means that we first execute the integration over x, then the integration over y, and finally the integration over z. However, any other order is possible. An equally valid way of writing the integral in equation 8.26 is

$$\int_V f\left(\vec{r}\right) dV = \int_{x_{\min}}^{x_{\max}} \left(\int_{y_{\min}}^{y_{\max}} \left(\int_{z_{\min}}^{z_{\max}} f\left(\vec{r}\right) dz \right) dy \right) dx, \quad \textbf{(8.27)}$$

which implies that the order of integration is now z, y, x. Why might the order of integration make a difference? The only time the order of the integration matters is when the integration boundaries in a particular coordinate depend on one or both of the other coordinates. Example 8.4 will consider such a situation.

Because the angle ϕ is one of the coordinates in the cylindrical coordinate system, the volume element is not cube-shaped. For a given differential angle, $d\phi$, the size of the volume element depends on how far away from the z-axis the volume element is located. This size increases linearly with the distance $r_\perp$ from the z-axis (Figure 8.18) and is given by

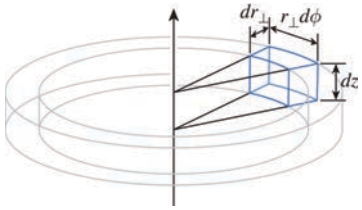

FIGURE 8.18
Volume element in cylindrical coordinates.

$$dV = r_\perp dr_\perp d\phi dz. \tag{8.28}$$

The volume integral is then

$$\int_V f\left(\vec{r}\right) dV = \int_{z_{\min}}^{z_{\max}} \left(\int_{\phi_{\min}}^{\phi_{\max}} \left(\int_{r_{\perp\min}}^{r_{\perp\max}} f\left(\vec{r}\right) r_\perp dr_\perp \right) d\phi \right) dz. \tag{8.29}$$

Again the order of integration can be chosen to make the task as simple as possible.

Finally, in spherical coordinates, we use two angular variables, θ and ϕ (Figure 8.19). Here the size of the volume element for a given value of the differential coordinates depends on the distance r to the origin as well as the angle relative to the $\theta = 0$ axis (equivalent to the z-axis in Cartesian or cylindrical coordinates). The differential volume element in spherical coordinates is

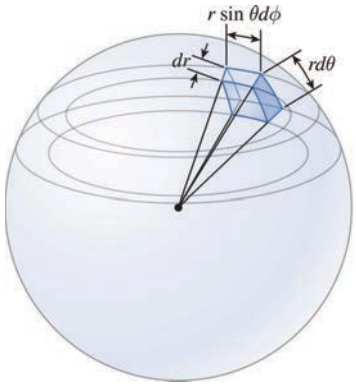

FIGURE 8.19
Volume element in spherical coordinates.

$$dV = r^2 dr \sin\theta d\theta d\phi. \tag{8.30}$$

The volume integral in spherical coordinates is

$$\int_V f\left(\overrightarrow{r}\right) dV = . \int_{r_{\min}}^{r_{\max}} \left(\int_{\phi_{\min}}^{\phi_{\max}} \left(\int_{\theta_{\min}}^{\theta_{\max}} f\left(\overrightarrow{r}\right) \sin\theta d\theta \right) d\phi \right) r^2 dr \quad \textbf{(8.}$$

EXAMPLE 8.4 Volume of a Cylinder

To illustrate why it may be simpler to use non-Cartesian coordinates in certain circumstances, let's use volume integrals to find the volume of a cylinder with radius R and height H. We have to integrate the function $f\left(\vec{r}\right) = 1$ over the entire cylinder to obtain the volume.

PROBLEM

Use a volume integral to find the volume of a right cylinder of height H and radius R.

SOLUTION

In Cartesian coordinates, we place the origin of our coordinate system at the center of the cylinder's circular base (bottom surface), so that the shape in the xy-plane that we have to integrate over is a circle with radius R (Figure 8.20). The volume integral in Cartesian coordinates is then

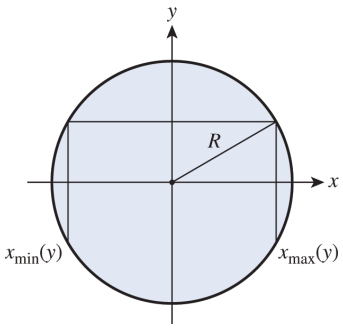

FIGURE 8.20
Bottom surface of a right cylinder of radius R.

$$\int_V dV = \int_0^H \left(\int_{y_{\min}}^{y_{\max}} \left(\int_{x_{\min}(y)}^{x_{\max}(y)} dx \right) dy \right) dz. \qquad \text{(i)}$$

The innermost integral has to be done first and is straightforward:

$$\int_{x_{\min}(y)}^{x_{\max}(y)} dx = x_{\max}(y) - x_{\min}(y). \qquad \text{(ii)}$$

The integration boundaries depend on y: $x_{\max} = \sqrt{R^2 - y^2}$ and $x_{\min} = -\sqrt{R^2 - y^2}$. Thus, the solution of equation (ii) is $x_{\max}(y) - x_{\min}(y) = 2\sqrt{R^2 - y^2}$. We insert this into equation (i) and obtain

$$\int_V dV = \int_0^H \left(\int_{-R}^{R} 2\sqrt{R^2 - y^2} dy \right) dz. \qquad \text{(iii)}$$

The inner of these two remaining integrals evaluates to

$$\int_{-R}^{R} 2\sqrt{R^2 - y^2} dy = \left(y\sqrt{R^2 - y^2} + R^2 \tan^{-1} \left(\frac{y}{\sqrt{R^2 - y^2}} \right.$$

You can check this result by looking up the definite integral in an integral table. Inserting this result into equation (iii) finally yields our answer:

$$\int_V dV = \int_0^H \pi R^2 dz = \pi R^2 \int_0^H dz = \pi R^2 H.$$

As you can see, obtaining the volume of the cylinder was rather cumbersome in Cartesian coordinates. What about using cylindrical coordinates? According to equation 8.29, the volume integral is then

$$\int_V dV = dz = dz \int_0^H \left(\int_0^{2\pi}, \left(\int_0^R, r_\perp, d, r_\perp \right), d, \phi \right) \int_0^H \left(\int_0^{2\pi}, ($$

$$= R^2 = R^2 = \pi R^2 . \frac{1}{2} \int_0^H \left(\int_0^{2\pi}, d, \phi \right) dz \frac{1}{2} \int_0^H 2\pi dz \int_0$$

In this case, it was much easier to use cylindrical coordinates, a consequence of the geometry of the object over which we had to integrate.

Self-Test Opportunity 8.2

Using spherical coordinates, show that the volume V of a sphere with radius R is $V = \frac{4}{3}\pi R^3$.

Now we can return to the problem of calculating the location of an object's center of mass. For the Cartesian components of the position vector, we find, from equation 8.21:

$$X = \frac{1}{M} \int_V x\rho\left(\vec{r}\right) dV, \quad Y = \frac{1}{M} \int_V y\rho\left(\vec{r}\right) dV, \quad Z = \frac{1}{M} \int_V$$

If the mass density for the entire object is constant, $\rho\left(\overrightarrow{r}\right) \equiv \rho$, we can remove this constant factor from the integral and obtain a special case of equation 8.21 for constant mass density:

$$\overrightarrow{R} = \frac{\rho}{M}\int_V \overrightarrow{r} dV = \frac{1}{V}\int_V \overrightarrow{r}\, dV (\text{for constant } \rho), \quad \textbf{(8.33)}$$

where we have used equation 8.20 in the last step. In Cartesian components, we obtain for this case:

$$X = \frac{1}{V}\int_V x dV, \quad Y = \frac{1}{V}\int_V y dV, \quad Z = \frac{1}{V}\int_V z dV. \quad \textbf{(8.34)}$$

Equations 8.33 and 8.34 indicate that any object that has a symmetry plane has its center of mass located in that plane. An object having three mutually perpendicular symmetry planes (such as a cylinder, a rectangular solid, or a sphere) has its center of mass where these three planes intersect, which is the geometric center. Example 8.5 develops this idea further.

EXAMPLE 8.5 Center of Mass for a Half-Sphere

PROBLEM

Consider a solid half-sphere of constant mass density with radius R_0 (Figure 8.21a). Where is its center of mass?

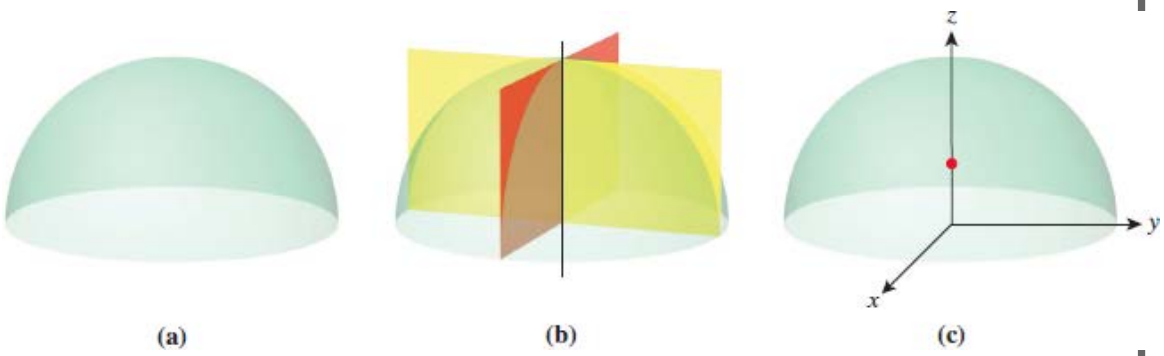

FIGURE 8.21 Determination of the center of mass: (a) half-sphere; (b) symmetry planes and symmetry axis; (c) coordinate system, with location of center of mass marked by red dot.

SOLUTION

As shown in Figure 8.21b, symmetry planes can divide this object into equal, mirror-image halves. Shown are two perpendicular planes in red and yellow, but any plane through the vertical symmetry axis (indicated by the thin black line) is a symmetry plane.

We now position the coordinate system so that one axis (the z-axis, in this case) coincides with this symmetry axis. We are then assured that the center of mass is located exactly on this axis. Because the mass distribution is symmetric and the integrands of equation 8.33 or 8.34 are odd powers of $\vec{r}$, the integral for X or Y has to have the value zero. Specifically,

$$\int_{-a}^{a} x\,dx = 0 \text{ for all values of the constant } a.$$

Positioning the coordinate system so that the z-axis is the symmetry axis ensures that $X = Y = 0$. This is shown in Figure 8.21c, where the origin of the coordinate system is positioned at the center of the half-sphere's circular bottom surface.

Now we have to find the value of the third integral in equation 8.34:

$$Z = \frac{1}{V}\int_V z dV.$$

The volume of a half-sphere is half the volume of a sphere, or

$$V = \frac{2\pi}{3}R_0^3. \qquad \text{(i)}$$

To evaluate the integral for Z, we use cylindrical coordinates, in which the differential volume element is given (see equation 8.28) as $dV = r_\perp dr_\perp d\phi dz$. The integral is then evaluated as follows:

$$\begin{aligned}\int_V z dV &= \int_0^{R_0}\left(\int_0^{\sqrt{R_0^2-z^2}}\left(\int_0^{2\pi} z r_\perp d\phi\right) dr_\perp\right) dz = \int_0^{R_0} z\left(\int_0^{\sqrt{R_0^2-}}\right.\\ &= 2\pi\int_0^{R_0} z\left(\int_0^{\sqrt{R_0^2-z^2}} r_\perp dr_\perp\right) dz = \pi\int_0^{R_0} z\left(R_0^2 - z^2\right)d\\ &= \frac{\pi}{4}R_0^4.\end{aligned}$$

Combining this result and the expression for the volume of a half-sphere from equation (i), we obtain the z-coordinate of the center of mass:

$$Z = \frac{1}{V}\int_V z dV = \frac{3}{2\pi R_0^3}\frac{\pi R_0^4}{4} = \frac{3}{8}R_0.$$

Note that the center of mass of an object does not always have to be located inside the object. Two obvious examples are shown in Figure 8.22. From symmetry considerations, it follows that the center of mass of the donut (Figure 8.22a) is exactly in the center of its hole, at a point outside the donut. The center of mass of the boomerang (Figure 8.22b) lies on the dashed symmetry axis but, again, outside the object.

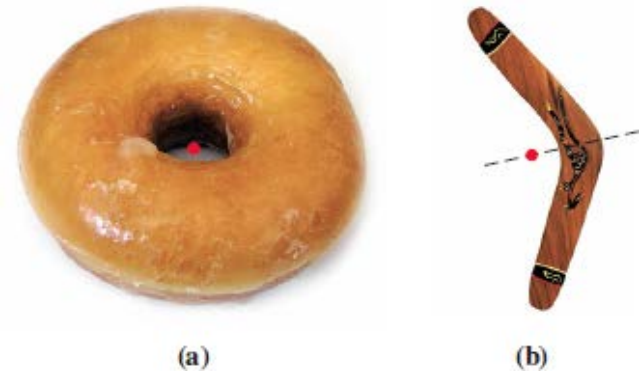

FIGURE 8.22 Objects with a center of mass (indicated by the red dot) outside their mass distribution: (a) donut; (b) boomerang. The symmetry axis of the boomerang is shown by a dashed line.

SOLVED PROBLEM 8.4 Center of Mass of a Disk with a Hole in It

PROBLEM

Where is the center of mass of a disk with a rectangular hole in it (Figure 8.23)? The height of the disk is $h = 11.0\,\text{cm}$, and its radius is $R = 11.5\,\text{cm}$, The rectangular hole has a width $w = 7.0\,\text{cm}$ and a depth $d = 8.0\,\text{cm}$. The right side of the hole is located so that its midpoint coincides with the central axis of the disk.

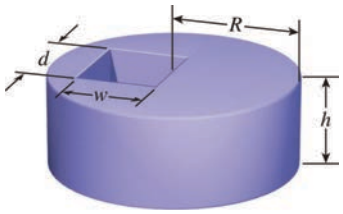

FIGURE 8.23
Three-dimensional view of a disk with a rectangular hole in it.

SOLUTION

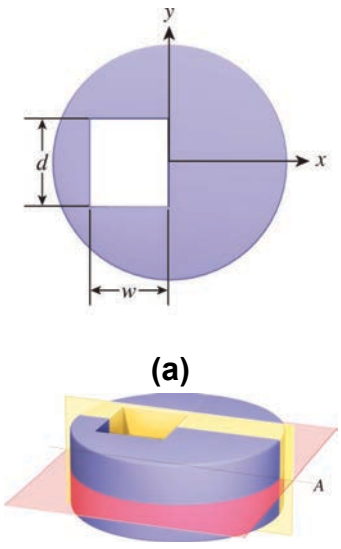
THINK

One way to approach this problem is to write mathematical formulas that describe the three-dimensional geometry of the disk with a hole in it and then integrate over that volume to obtain the coordinates of the center of mass. If we did that, we would be faced with several difficult integrals. A simpler way to approach this problem is to think of the disk with a hole in it as a solid disk *minus* a rectangular hole. That is, we treat the hole as a solid object with a negative mass. Using the symmetry of the solid disk and of the hole, we can specify the coordinates of the center of mass of the solid disk and of the center of mass of the hole. We can then combine these coordinates, using equation 8.1, to find the center of mass of the disk with a hole in it.

SKETCH

Figure 8.24a shows a top view of the disk with a hole in it, with x- and y-axes assigned.

Figure 8.24b shows the two symmetry planes of the disk with a hole in it. One plane corresponds to the x-y plane, and the second plane is a plane along the x-axis and perpendicular to the x-y plane. The line where the two planes intersect is marked A.



(a)

(b)

FIGURE 8.24 (a) Top view of the disk with a hole in it with a coordinate system assigned. (b) Symmetry planes of the disk with a hole in it.

RESEARCH

The center of mass must lie along the intersection of the two planes of symmetry. Therefore, we know that the center of mass can only be located along the x-axis. The center of mass for the disk without the hole is at the origin of the coordinate system, at

$x_{\mathrm{d}} = 0$, and the volume of the solid disk is $V_{\mathrm{d}} = \pi R^2 h$. If the hole were a solid object with the same dimensions ($h = 11.0\,\mathrm{cm}, w = 7.0\,\mathrm{cm}$, and $d = 8.0\,\mathrm{cm}$), that object would have a volume of $V_{\mathrm{h}} = hwd$. If this imagined solid object were located where the hole is, its center of mass would be in the middle of the hole, at $x_{\mathrm{h}} = -3.5\,\mathrm{cm}$. We now multiply each of the volumes by ρ, density of the material of the disk, to get the corresponding masses, and assign a negative mass to the hole. Then we use equation 8.1 to get the x-coordinate of the center of mass:

$$X = \frac{x_{\mathrm{d}} V_{\mathrm{d}} \rho - x_{\mathrm{h}} V_{\mathrm{h}} \rho}{V_{\mathrm{d}} \rho - V_{\mathrm{h}} \rho}. \qquad \text{(i)}$$

This method of treating a hole as an object of the same shape and then using its volume in calculations, but with negative mass (or charge), is very common in atomic and subatomic physics. We will encounter it again when we explore atomic physics (Chapter 37) and nuclear and particle physics (Chapters 39 and 40).

SIMPLIFY

We can simplify equation (i) by realizing that $x_{\mathrm{d}} = 0$ and that ρ is a common factor:

$$X = \frac{-x_{\mathrm{h}} V_{\mathrm{h}}}{V_{\mathrm{d}} - V_{\mathrm{h}}}.$$

Substituting the expressions we obtained for V_{d} and $V_{\mathrm{h},}$ we get

$$X = \frac{-x_{\mathrm{h}} V_{\mathrm{h}}}{V_{\mathrm{d}} - V_{\mathrm{h}}} = \frac{-x_{\mathrm{h}} (hwd)}{\pi R^2 h - hwd} = \frac{-x_{\mathrm{h}} wd}{\pi R^2 - wd}.$$

Defining the area of the disk in the x-y plane to be $A_{\mathrm{d}} = \pi R^2$ and the area of the hole in the x-y plane to be $A_{\mathrm{h}} = wd$, we can write

$$X = \frac{-x_{\mathrm{h}} wd}{\pi R^2 - wd} = \frac{-x_{\mathrm{h}} A_{\mathrm{h}}}{A_{\mathrm{d}} - A_{\mathrm{h}}}.$$

CALCULATE

Inserting the given numbers, we find that the area of the disk is

$$A_{\mathrm{d}} = \pi R^2 = \pi(11.5\ \mathrm{cm})^2 = 415.475\ \mathrm{cm}^2,$$

and the area of the hole is

$$A_{\mathrm{h}} = wd = (7.0\ \mathrm{cm})(8.0\ \mathrm{cm}) = 56\ \mathrm{cm}^2.$$

Therefore, the location of the center of mass of the disk with the hole in it (remember that $x_{\mathrm{h}} = -3.5\ \mathrm{cm}$) is

$$X = \frac{-x_{\mathrm{h}}A_{\mathrm{h}}}{A_{\mathrm{d}} - A_{\mathrm{h}}} = \frac{-(-3.5\ \mathrm{cm})\left(56\ \mathrm{cm}^2\right)}{(415.475\ \mathrm{cm}^2) - (56\ \mathrm{cm}^2)} = 0.545239\ \mathrm{c}$$

ROUND

Expressing our answer with two significant figures, we report the x-coordinate of the center of mass of the disk with a hole in it as

$$X = 0.55\ \mathrm{cm}.$$

DOUBLE-CHECK

This point is slightly to the right of the center of the solid disk, by a distance that is a small fraction of the radius of the disk. This result seems reasonable because taking material out of the disk to the left of $x = 0$ should shift the center of gravity to the right, just as we calculated.

Center of Mass for One- and Two-Dimensional Objects

Not all problems involving calculation of a center of mass focus on three-dimensional objects. For example, you may want to calculate the center of mass of a two-dimensional object, such as a flat metal plate. We can write the equations for the center-of-mass coordinates of a two-dimensional object whose area mass density (or mass per unit area) is $\sigma\left(\vec{r}\right)$ by modifying the expressions for X and Y given in equation 8.32:

$$X = \frac{1}{M}\int_A x\sigma\left(\vec{r}\right)dA, \quad Y = \frac{1}{M}\int_A y\sigma\left(\vec{r}\right)dA, \tag{8.35}$$

where the mass is

$$M = \int_A \sigma\left(\vec{r}\right)dA. \tag{8.36}$$

If the area mass density of the object is constant, then $\sigma = M/A$, and we can rewrite equation 8.35 to give the coordinates of the center of mass of a two-dimensional object in terms of the area, A, and the coordinates x and y:

$$X = \frac{1}{A}\int_A xdA, \quad Y = \frac{1}{A}\int_A ydA, \tag{8.37}$$

where the total area is obtained from

$$A = \int_A dA. \tag{8.38}$$

If the object is effectively one-dimensional, such as a long, thin rod with length L and linear mass density (or mass per unit length) $\lambda(x)$, the coordinate of the center of mass is given by

$$X = \frac{1}{M} \int_L x\lambda(x)dx, \tag{8.39}$$

where the mass is

$$M = \int_L \lambda(x)dx. \tag{8.40}$$

If the linear mass density of the rod is constant, then clearly the center of mass is located at the geometric center—the middle of the rod—and no further calculation is required.

SOLVED PROBLEM 8.5 Center of Mass of a Long, Thin Rod

PROBLEM

A long, thin rod lies along the x-axis. One end of the rod is located at $x = 1.00\,\text{m}$, and the other end of the rod is located at $x = 3.00\,\text{m}$. The linear mass density of the rod is given by $\lambda(x) = ax^2 + b$, where $a = 0.300\,\text{kg/m}^3$ and $b = 0.600\,\text{kg/m}$. What are the mass of the rod and the x-coordinate of its center of mass?

SOLUTION

THINK

The linear mass density of the rod is not uniform but depends on the x-coordinate. Therefore, to get the mass, we must integrate the linear mass density over the length of the rod. To get the center of mass, we need to integrate the linear mass density, weighted by the distance in the x-direction, and then divide by the mass of the rod.

SKETCH

The long, thin rod oriented along the x-axis is shown in Figure 8.25.

FIGURE 8.25 A long, thin rod oriented along the x-axis.

RESEARCH

We obtain the mass of the rod by integrating the linear mass density, λ, over the rod from $x_1 = 1.00\,\text{m}$ to $x_2 = 3.00\,\text{m}$ (see equation 8.40):

$$M = \int_{x_1}^{x_2} \lambda(x)dx = \int_{x_1}^{x_2} \left(ax^2 + b\right)dx = \left[a\frac{x^3}{3} + bx\right]_{x_1}^{x_2}.$$

To find the x-coordinate of the center of mass of the rod, X, we evaluate the integral of the differential mass times x and then divide by the mass, which we have just calculated (see equation 8.39):

$$X = \frac{1}{M}\int_{x_1}^{x_2} \lambda(x)xdx = \frac{1}{M}\int_{x_1}^{x_2} \left(ax^2 + b\right)xdx = \frac{1}{M}\int_{x_1}^{x_2} (ax$$

SIMPLIFY

Inserting the upper and lower limits, x_2 and x_1, we get the mass of the rod:

$$M = \left[a\frac{x^3}{3} + bx\right]_{x_1}^{x_2} = \left(a\frac{x_2^3}{3} + bx_2\right) - \left(a\frac{x_1^3}{3} + bx_1\right) =$$

And, in the same way, we find the x-coordinate of the center of mass of the rod:

$$X = \frac{1}{M}\left[a\frac{x^4}{4} + b\frac{x^2}{2}\right]_{x_1}^{x_2} = \frac{1}{M}\left\{\left(a\frac{x_2^4}{4} + b\frac{x_2^2}{2}\right) - \left(a\frac{x_1^4}{4}\right.\right.$$

which we can further simplify to

$$X = \frac{1}{M}\left\{\frac{a}{4}\left(x_2^4 - x_1^4\right) + \frac{b}{2}\left(x_2^2 - x_1^2\right)\right\}.$$

CALCULATE

Substituting the given numerical values, we compute the mass of the rod:

$$M = \frac{0.300\ \text{kg/m}^3}{3}\left((3.00\ \text{m})^3 - (1.00\ \text{m})^3\right) + (0.600\ \text{l}$$

With the numerical values, the x-coordinate of the rod is

$$\begin{aligned} X &= \frac{1}{3.8\ \text{kg}}\left\{\frac{0.300\ \text{kg/m}^3}{4}\left((3.00\ \text{m})^4 - (1.00\ \text{m})^4\right) + \right. \\ &= 2.210526316\ \text{m}. \end{aligned}$$

ROUND

All of the numerical values in the problem statement were specified to three significant figures, so we report our results as

$$M = 3.80\ \text{kg}$$

and

$$X = 2.21\ \text{m}.$$

DOUBLE-CHECK

To double-check our answer for the mass of the rod, let's assume that the rod has a constant linear mass density equal to the linear mass density obtained by setting $x = 2\ \text{m}$ (the middle of the rod) in the expression for *l* given in the problem, that is,

$$\lambda = (0.3 \cdot 4 + 0.6)\ \text{kg/m} = 1.8\ \text{kg/m}.$$

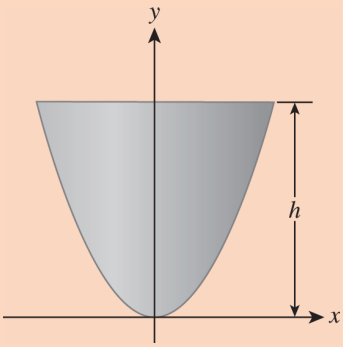
The mass of the rod is then $m \approx 2\ \text{m} \cdot 1.8\ \ \text{kg/m} = 3.6\ \text{kg}$, which is reasonably close to our exact calculation of $M = 3.80\ \text{kg}$.

To double-check the x-coordinate of the center of mass of the rod, we again assume that the linear mass density is constant. Then the center of mass will be located at the middle of the rod, or $X \approx 2\ \text{m}$. Our calculated answer is $X = 2.21\ \text{m}$, which is slightly to the right of the middle of the rod. Looking at the function for the linear mass density, we see that the linear mass of the rod increases toward the right, which means that the

center of mass of the rod must be to the right of the rod's geometric center. Our result is therefore reasonable.

Self-Test Opportunity 8.3

A plate with height h is cut from a thin metal sheet with uniform mass density, as shown in the figure. The lower boundary of the plate is defined by $y = 2x^2$. Show that the center of mass of this plate is located at $x = 0$ and $y = \frac{3}{5}h$.



WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- The center of mass is the point at which we can imagine all the mass of an object to be concentrated.
- The location of the center of mass for an arbitrarily shaped object is given by $\vec{R} = \frac{1}{M}\int_V \vec{r}\rho\left(\vec{r}\right)dV$, where the mass density of the object is $\rho = \frac{dm}{dV}$, the integration extends over the entire volume V of the object, and M is its total mass.
- When the mass density is uniform throughout the object, that is, $\rho = \frac{M}{V}$, the center of mass is at $\vec{R} = \frac{1}{V}\int_V \vec{r}dV$.
- If an object has a plane of symmetry, the location of the center of mass must be in that plane.
- The location of the center of mass for a combination of several objects can be found by taking the mass-weighted average of the locations of the centers of mass of the individual objects:

$$\vec{R} = \frac{\vec{r}_1 m_1 + \vec{r}_2 m_2 + \cdots + \vec{r}_n m_n}{m_1 + m_2 + \cdots + m_n} = \frac{1}{M}\sum_{i=1}^{n} \vec{r}_i m_i.$$

- The motion of an extended rigid object can be described by the motion of its center of mass.
- The velocity of the center of mass is given by the derivative of its position vector: $\vec{V} \equiv \frac{d}{dt}\vec{R}$.
- The center-of-mass momentum for a combination of several objects is $\vec{P} = M\vec{V} = \sum_{i=1}^{n} \vec{p}_i$. This momentum obeys

Newton's Second Law: $\frac{d}{dt}\vec{P} = \frac{d}{dt}\left(M\vec{V}\right) = \sum_{i=1}^{n}\vec{F}_i = \vec{F}_{\text{net}}$.

Internal forces between the objects do not contribute to the sum that yields the net force (because they always come in action-reaction pairs adding up to zero) and thus do not change the center-of-mass momentum.

- Rocket motion is an example of motion during which the mass of the moving object is not constant. The equation of motion for a rocket in interstellar space is given by $\vec{F}_{\text{thrust}} = m\vec{a} = -\vec{v}_{\text{c}}\frac{dm}{dt}$, where $\vec{v}_{\text{c}}$ is the velocity of the propellant relative to the rocket and $\frac{dm}{dt}$ is the rate of change in mass due to outflow of propellant.
- The speed of a rocket as a function of its mass is given by $v_{\text{f}} - v_{\text{i}} = v_{\text{c}}\ \ln\left(m_{\text{i}}/m_{\text{f}}\right)$, where the indices i and f indicate initial and final masses and speeds.

ANSWERS TO SELF-TEST OPPORTUNITIES

8.1

$$
\begin{aligned}
Z &= \frac{z_{\text{red}}m_{\text{red}} + z_{\text{green}}m_{\text{green}} + z_{\text{orange}}m_{\text{orange}} + z_{\text{blue}}m_{\text{blue}} + z_{\text{p}}}{M} \\
&= \frac{\frac{1}{2}h2m_0 + \frac{1}{2}hm_0 + \frac{1}{2}hm_0 + \frac{1}{2}hm_0 + \frac{3}{2}hm_0}{6m_0} \\
&= \frac{h\left(1 + \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \frac{3}{2}\right)}{6} = \frac{2}{3}h = 1.7\,\text{m}.
\end{aligned}
$$

8.2 We use spherical coordinates and integrate the angle θ from 0 to π, the angle ϕ from 0 to 2π, and the radial coordinate r from 0 to R.

$$
V = \int_0^R \left(\int_0^{2\pi} \left(\int_0^{\pi} \sin\theta \, d\,\theta \right) d\phi \right) r^2 dr
$$

First, evaluate the integral over the azimuthal angle:

$$
\int_0^{\pi} \sin\theta d\theta = \left[-\cos\,\theta \right]_0^{\pi} = -\left[\cos\left(\pi\right) - \cos\left(0\right) \right] = 2
$$

$$
V = 2\int_0^R \left(\int_0^{2\pi} d\phi \right) r^2 dr
$$

Now evaluate the polar angle integral:

$$
\int_0^{2\pi} d\phi = \left[\phi \right]_0^{2\pi} = 2\pi
$$

Finally:

$$V = 4\pi \int_0^R r^2 dr = 4\pi \left[\frac{r^3}{3}\right]_0^R = \frac{4}{3}\pi R^3.$$

8.3 $dA = 2x(y)dy; y = 2x^2 \Rightarrow x = \sqrt{y/2}$

$2x(y) = 2\sqrt{y/2} = \sqrt{2y}; dA = \sqrt{2y}dy$

$$Y = \frac{\int_0^h y\sqrt{2y}\, dy}{\int_0^h \sqrt{2y}\, dy} = \frac{\sqrt{2}\int_0^h y^{3/2}\, \mathrm{dy}}{\sqrt{2}\int_0^h y^{1/2}\, \mathrm{dy}} = \frac{\left[\frac{y^{5/2}}{5/2}\right]_0^h}{\left[\frac{y^{3/2}}{3/2}\right]_0^h}$$

$Y = \frac{3}{5}h.\ (X = 0,\ \text{by symmetry}).$

PROBLEM-SOLVING GUIDELINES: CENTER OF MASS AND ROCKET MOTION

1. The first step in locating the center of mass of an object or a system of particles is to look for planes of symmetry. The center of mass must be located on the plane of symmetry, on the line of intersection of two planes of symmetry, or at the point of intersection of more than two planes.

2. For complicated shapes, break the object down into simpler geometric forms and locate the center of mass for each individual form. Then combine the separate centers of mass into one overall center of mass using the weighted average of distances and masses. Treat holes as objects of negative mass.

3. Any motion of an object can be treated as a superposition of motion of its center of mass (according to Newton's Second Law) and rotation of the object about the center of mass. Collisions can often be conveniently analyzed by considering a reference frame with the origin located at the center of mass.

4. Often, integration is unavoidable when you need to locate the center of mass. In such a case, it is always best to think carefully about the dimensionality of the situation and the choice of the coordinate system (Cartesian, cylindrical, or spherical).

5. In problems involving rocket motion, you cannot simply apply $F = ma$, because the mass of the rocket does not remain constant.

MULTIPLE-CHOICE QUESTIONS

8.1 A man standing on frictionless ice throws a boomerang, which returns to him. Choose the correct statement:

a) Since the momentum of the man-boomerang system is conserved, the man will come to rest holding the boomerang at the same location from which he threw it.

b) It is impossible for the man to throw a boomerang in this situation.

c) It is possible for the man to throw a boomerang, but because he is standing on frictionless ice when he throws it, the boomerang cannot return.

d) The total momentum of the man-boomerang system is not conserved, so the man will be sliding backward holding the boomerang after he catches it.

8.2 When a bismuth-208 nucleus at rest decays, thallium-204 is produced, along with an alpha particle (helium-4 nucleus). The mass numbers of bismuth-208, thallium-204, and helium-4 are 208, 204, and 4, respectively. (The mass number represents the total number of protons and neutrons in the nucleus.) The kinetic energy of the thallium nucleus is

a) equal to that of the alpha particle.

b) less than that of the alpha particle.

c) greater than that of the alpha particle.

8.3 Two objects with masses m_1 and m_2 are moving along the x-axis in the positive direction with speeds v_1 and v_2, respectively, where v_1 is less than v_2. The speed of the center of mass of this system of two bodies is

a) less than v_1.

b) equal to v_1.

c) equal to the average of v_1 and v_2.

d) greater than v_1 and less than v_2.

e) greater than v_2.

8.4 An artillery shell is moving on a parabolic trajectory when it explodes in midair. The shell shatters into a very large number of fragments. Which of the following statements is (are) true (select all that apply)?

a) The force of the explosion will increase the momentum of the system of fragments, and so the momentum of the shell is *not* conserved during the explosion.

b) The force of the explosion is an internal force and thus cannot alter the total momentum of the system.

c) The center of mass of the system of fragments will continue to move on the initial parabolic trajectory until the last fragment touches the ground.

d) The center of mass of the system of fragments will continue to move on the initial parabolic trajectory until the first fragment touches the ground.

e) The center of mass of the system of fragments will have a trajectory that depends on the number of fragments and their velocities right after the explosion.

8.5 An 80-kg astronaut becomes separated from his spaceship. He is 15.0 m away from it and at rest relative to it. In an effort to get back, he throws a 500-g object with a speed of 8.0 m/s in a direction away from the ship. How long does it take him to get back to the ship?

a) 1 s

b) 10 s

c) 20 s

d) 200 s

e) 300 s

8.6 You find yourself in the (realistic?) situation of being stuck on a 300-kg raft (including yourself) in the middle of a pond with nothing but a pile of 7-kg bowling balls and 55-g tennis balls. Using your knowledge of rocket propulsion, you decide to start throwing balls

from the raft to move toward shore. Which of the following will allow you to reach the shore faster?

a) throwing the tennis balls at 35 m/s at a rate of 1 tennis ball per second

b) throwing the bowling balls at 0.5 m/s at a rate of 1 bowling ball every 3 s

c) throwing a tennis ball and a bowling ball simultaneously, with the tennis ball moving at 15 m/s and the bowling ball moving at 0.3 m/s, at a rate of 1 tennis ball and 1 bowling ball every 4 s

d) not enough information to decide

8.7 The figures show a high jumper using different techniques to get over the crossbar. Which technique would allow the jumper to clear the highest setting of the bar?

8.8 The center of mass of an irregular rigid object is *always* located

a) at the geometrical center of the object.

b) somewhere within the object.

c) both of these answers

d) neither of these answers

8.9 A catapult on a level field tosses a 3-kg stone a horizontal distance of 100 m. A second 3-kg stone tossed in an identical fashion breaks apart in the air into two pieces, one with a mass of 1 kg and one with a mass of 2 kg. Both of the pieces hit the ground at the same time. If the 1-kg piece lands a distance of 180 m away from the

catapult, how far away from the catapult does the 2-kg piece land? Ignore air resistance.

a) 20 m

b) 60 m

c) 100 m

d) 120 m

e) 180 m

8.10 Two point masses are located in the same plane. The distance from mass 1 to the center of mass is 3.0 m. The distance from mass 2 to the center of mass is 1.0 m. What is m_1/m_2, the ratio of mass 1 to mass 2?

a) $3/4$

b) $4/3$

c) $4/7$

d) $7/4$

e) $1/3$

f) $3/1$

8.11 A cylindrical bottle of oil-and-vinegar salad dressing whose volume is $1/3$ vinegar $\left(\rho = 1.01\ \text{g/cm}^3\right)$ and $2/3$ oil $\left(\rho = 0.910\ \text{g/cm}^3\right)$ is at rest on a table. Initially, the oil and the vinegar are separated, with the oil floating on top of the vinegar. The bottle is shaken so that the oil and vinegar mix uniformly, and the bottle is returned to the table. How has the height of the center of mass of the salad dressing changed as a result of the mixing?

a) It is higher.

b) It is lower.

c) It is the same.

d) There is not enough information to answer this question.

8.12 A one-dimensional rod has a linear density that varies with position according to the relationship $\lambda(x) = cx$, where c is a

constant and $x = 0$ is the left end of the rod. Where do you expect the center of mass to be located?

a) the middle of the rod

b) to the left of the middle of the rod

c) to the right of the middle of the rod

d) at the right end of the rod

e) at the left end of the rod.

8.13 A garden hose is used to fill a 20-L bucket in 1 min. The speed of the water leaving the hose is $1.05\ \mathrm{m/s}$. What force acts on the person holding the hose?

a) 0.35 N

b) 2.1 N

c) 9.8 N

d) 12 N

e) 21 N

8.14 A garden hose is used to fill a 20-L bucket in 1 min. The speed of the water leaving the hose is $2.35\ \mathrm{m/s}$. A force F is acting on the person holding the hose. Another hose can fill the same bucket in 2 min, with the water having the same speed leaving this hose. The force acting on the person holding this hose is

a) $F/4$

b) $F/2$

c) F

d) $2F$

e) $4F$

8.15 Consider a rocket firing in the vacuum of outer space. Which of the following statements is (are) true?

a) The rocket will not produce any thrust because there is no air to push against.

b) The rocket will produce the same thrust in vacuum that it can produce in air.

c) The rocket will produce half the thrust in vacuum that it can produce in air.

d) The rocket will produce twice the thrust in vacuum that it can produce in air.

8.16 The center of mass of the Sun and Jupiter is located

a) exactly at the center of the Sun.

b) near the center of the Sun.

c) exactly at the center of Jupiter.

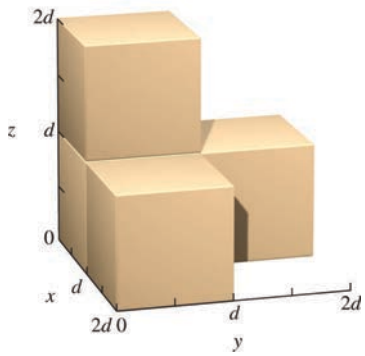
d) near the center of Jupiter.

e) halfway between the Sun and Jupiter.

CONCEPTUAL QUESTIONS

8.17 A projectile is launched into the air. Part way through its flight, it explodes. How does the explosion affect the motion of the center of mass of the projectile?

8.18 Find the center of mass of the arrangement of uniform identical cubes shown in the figure. The length of the sides of the each cube is d.



8.19 A model rocket that has a horizontal range of 100 m is fired. A small explosion splits the rocket into two equal parts. What can you say about the points where the fragments land on the ground?

8.20 Can the center of mass of an object be located at a point outside the object, that is, at a point in space where no part of the object is located? Explain.

8.21 Is it possible for two masses to undergo a collision such that the system of two masses has more kinetic energy than the two separate masses had? Explain.

8.22 Prove that the center of mass of a thin metal plate in the shape of an equilateral triangle is located at the intersection of the triangle's altitudes by direct calculation and by physical reasoning.

8.23 A soda can of mass m and height L is filled with soda of mass M. A hole is punched in the bottom of the can to drain out the soda.

a) What is the center of mass of the system consisting of the can and the soda remaining in it when the level of soda in the can is h, where $0 < h < L$?

b) What is the minimum value of the center of mass as the soda drains out?

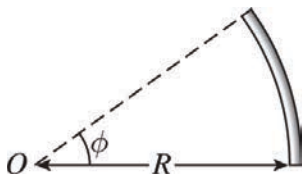
8.24 An astronaut of mass M is floating in space at a constant distance D from his spaceship when his safety line breaks. He is carrying a toolbox of mass $M/2$ that contains a big sledgehammer of mass $M/4$, for a total mass of $3M/4$. He can throw the items with a speed v relative to his final speed after each item is thrown. He wants to return to the spaceship as soon as possible.

a) To attain the maximum final speed, should the astronaut throw the two items together, or should he throw them one at a time? Explain.

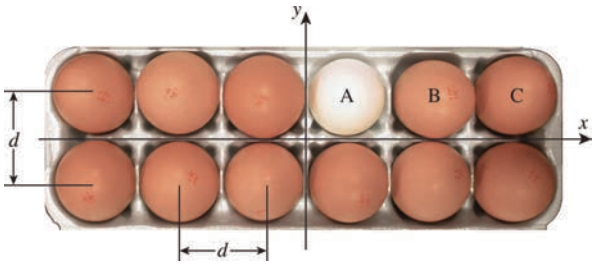
b) To attain the maximum speed, is it best to throw the hammer first or the toolbox first, or does the order make no difference? Explain.

c) Find the maximum speed at which the astronaut can start moving toward the spaceship.

8.25 A metal rod with a length density (mass per unit length) λ is bent into a circular arc of radius R and subtending a total angle of ϕ, as shown in the figure. What is the distance of the center of mass of this arc from O as a function of the angle ϕ? Plot this center-of-mass coordinate as a function of ϕ.



8.26 The carton shown in the figure is filled with a dozen eggs, each of mass m. Initially, the center of mass of the eggs is at the center of the carton, which is the same point as the origin of the Cartesian coordinate system shown. Where is the center of mass of the remaining eggs, in terms of the egg-to-egg distance d, in each of the following situations? Neglect the mass of the carton.



W. Bauer and G. D. Westfall

a) Only egg A is removed.

b) Only egg B is removed.

c) Only egg C is removed.

d) Eggs A, B, and C are removed.

8.27 A circular pizza of radius R has a circular piece of radius $R/4$ removed from one side, as shown in the figure. Where is the center of mass of the pizza with the hole in it?

8.28 Suppose you place an old-fashioned hourglass, with sand in the bottom, on a very sensitive analytical balance to determine its mass. You then turn it over (handling it with very clean gloves) and place it back on the balance. You want to predict whether the reading on the balance will be less than, greater than, or the same as before. What do you need to calculate to answer this question? Explain carefully what should be calculated and what the results would imply. You do not need to attempt the calculation.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

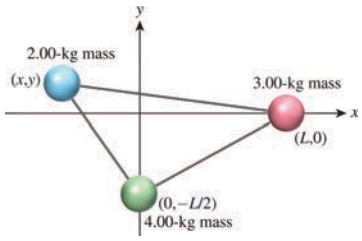
Section 8.1

8.29 Find the following center-of-mass information about objects in the Solar System. You can look up the necessary data on the Internet or in the tables in Chapter 12 of this book. Assume spherically symmetrical mass distributions for all objects under consideration.

a) Determine the distance from the center of mass of the Earth-Moon system to the geometric center of Earth.

b) Determine the distance from the center of mass of the Sun-Jupiter system to the geometric center of the Sun.

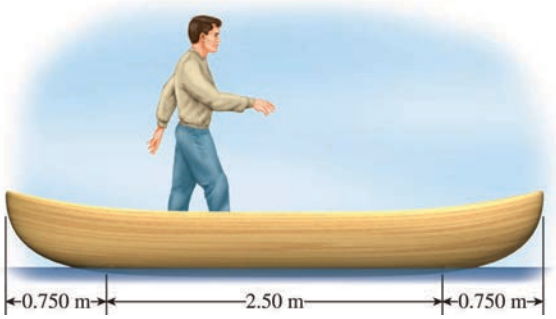
•**8.30** The coordinates of the center of mass for the extended object shown in the figure are $(L/4, -L/5)$. What are the coordinates of the 2.00-kg mass?



•**8.31** Young acrobats are standing still on a circular horizontal platform suspended at the center. The origin of the two-dimensional Cartesian coordinate system is assumed to be at the center of the platform. A 30.0-kg acrobat is located at (3.00 m, 4.00 m), and a 40.0-kg acrobat is located at $(-2.00\ \text{m},\ -2.00\ \text{m})$. Assuming that the acrobats stand still in their positions, where must a 20.0-kg acrobat be located so that the center of mass of the system consisting of the three acrobats is at the origin and the platform is balanced?

Section 8.2

8.32 A man with a mass of 55.0 kg stands up in a 65.0-kg canoe of length 4.00 m floating on water. He walks from a point 0.750 m from the back of the canoe to a point 0.750 m from the front of the canoe. Assume negligible friction between the canoe and the water. How far does the canoe move?

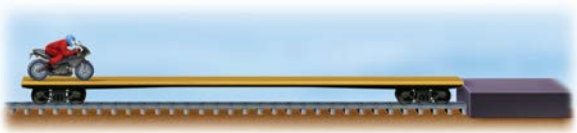


8.33 A toy car of mass 2.00 kg is stationary, and a child rolls a toy truck of mass 3.50 kg straight toward it with a speed of 4.00 m/s. The toy car and truck then undergo an elastic collision.

a) What is the velocity of the center of mass of the system consisting of the two toys?

b) What are the velocities of the truck and the car with respect to the center of mass of the system consisting of the two toys before and after the collision?

8.34 A motorcycle stunt rider plans to start from one end of a railroad flatcar, accelerate toward the other end of the car, and jump from the flatcar to a platform. The motorcycle and rider have a mass of 350. kg and a length of 2.00 m. The flatcar has a mass of 1500. kg and a length of 20.0 m. Assume that there is negligible friction between the flatcar's wheels and the rails and that the motorcycle and rider can move through the air with negligible resistance. The flatcar is initially touching the platform. The promoters of the event have asked you how far the flatcar will be from the platform when the stunt rider reaches the end of the flatcar. What is your answer?



•**8.35** Starting at rest, two students stand on 10.0-kg sleds, which point away from each other on ice, and they pass a 5.00-kg medicine ball back and forth. The student on the left has a mass of 50.0 kg and can throw the ball with a relative speed of 10.0 m/s. The student on the right has a mass of 45.0 kg and can throw the ball with a relative speed of 12.0 m/s. (Assume there is no friction between the ice and the sleds and no air resistance.)

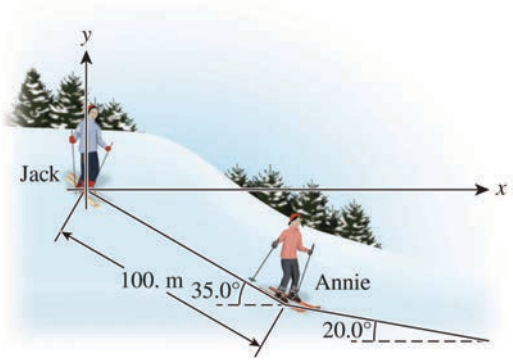
a) If the student on the left throws the ball horizontally to the student on the right, how fast is the student on the left moving right after the throw?

b) How fast is the student on the right moving right after catching the ball?

c) If the student on the right passes the ball back, how fast will the student on the left be moving after catching the pass from the student on the right?

d) How fast is the student on the right moving after the pass?

•**8.36** Two skiers, Annie and Jack, start skiing from rest at different points on a hill at the same time. Jack, with mass 88.0 kg, skis from the top of the hill down a steeper section with an angle of inclination of 35.0°. Annie, with mass 64.0 kg, starts from a lower point and skis a less steep section, with an angle of inclination of 20.0°. The length of the steeper section is 100. m. Determine the acceleration, velocity, and position vectors of the combined center of mass for Annie and Jack as a function of time before Jack reaches the less steep section.



•**8.37** Many nuclear collisions studied in laboratories are analyzed in a frame of reference relative to the laboratory. A proton, with a mass of $1.6726 \cdot 10^{-27}$ kg and traveling at a speed of 70.0% of the speed of light, c, collides with a tin-116 $\left({}^{116}\text{Sn}\right)$ nucleus with a mass of $1.9240 \cdot 10^{-25}$ kg. What is the speed of the center of mass with respect to the laboratory frame? Answer in terms of c, the speed of light.

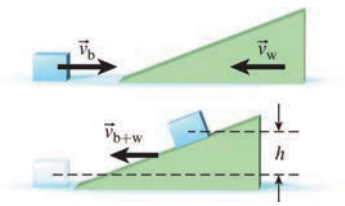
•**8.38** A system consists of two particles. Particle 1 with mass 2.00 kg is located at (2.00 m, 6.00 m) and has a velocity of $(4.00\ \text{m/s},\ 2.00\ \text{m/s})$. Particle 2 with mass 3.00 kg is located at (4.00 m, 1.00 m) and has a velocity of $(0,\ 4.00\ \text{m/s})$.

a) Determine the position and the velocity of the center of mass of the system.

b) Sketch the position and velocity vectors for the individual particles and for the center of mass.

•**8.39** A fire hose 4.00 cm in diameter is capable of spraying water at a velocity of 10.0 m/s. For a continuous horizontal flow of water, what horizontal force should a firefighter exert on the hose to keep it stationary?

••**8.40** A block of mass $m_\text{b} = 1.20$ kg slides to the right at a speed of 2.50 m/s on a frictionless horizontal surface, as shown in the figure. It "collides" with a wedge of mass m_w, which moves to the left at a speed of 1.10 m/s. The wedge is shaped so that the block slides seamlessly up the Teflon (frictionless!) surface, as the two come together. Relative to the horizontal surface, block and wedge are moving with a common velocity $v_{\text{b+w}}$ at the instant the block stops sliding up the wedge.



a) If the block's center of mass rises by a distance $h = 0.370$ m, what is the mass of the wedge?

b) What is $v_{\text{b+w}}$?

Section 8.3

8.41 One important characteristic of rocket engines is the specific impulse, which is defined as the total impulse (time integral of the thrust) per unit ground weight of fuel/oxidizer expended. (The use of weight, instead of mass, in this definition is due to purely historical reasons.)

a) Consider a rocket engine operating in free space with an exhaust nozzle speed of v. Calculate the specific impulse of this engine.

b) A model rocket engine has a typical exhaust speed of $v_{\text{toy}} = 800.\ \text{m/s}$. The best chemical rocket engines have exhaust speeds of approximately $v_{\text{chem}} = 4.00\ \text{km/s}$. Evaluate and compare the specific impulse values for these engines.

•**8.42** An astronaut is performing a space walk outside the International Space Station. The total mass of the astronaut with her space suit and all her gear is 115 kg. A small leak develops in her propulsion system, and 7.00 g of gas is ejected each second into space with a speed of $800.\ \text{m/s}$. She notices the leak 6.00 s after it starts. How much will the gas leak have caused her to move from her original location in space by that time?

•**8.43** A rocket in outer space has a payload of 5190.0 kg and $1.551 \cdot 10^5$kg of fuel. The rocket can expel propellant at a speed of $5.600\ \text{km/s}$. Assume that the rocket starts from rest, accelerates to its final velocity, and then begins its trip. How long will it take the rocket to travel a distance of $3.82 \cdot 10^5\ \text{km}$ (approximately the distance between Earth and Moon)?

••**8.44** A uniform chain with a mass of 1.32 kg per meter of length is coiled on a table. One end is pulled upward at a constant rate of $0.470\ \text{m/s}$.

a) Calculate the net force acting on the chain.

b) At the instant when 0.150 m of the chain has been lifted off the table, how much force must be applied to the end being raised?

••**8.45** A spacecraft engine creates 53.2 MN of thrust with a propellant velocity of $4.78\ \text{km/s}$.

a) Find the rate (dm/dt) at which the propellant is expelled.

b) If the initial mass is $2.12 \cdot 10^6$ kg and the final mass is $7.04 \cdot 10^4$ kg, find the final speed of the spacecraft (assume the initial speed is zero and any gravitational fields are small enough to be ignored).

c) Find the average acceleration till burnout (the time at which the propellant is used up; assume the mass flow rate is constant until that time).

••**8.46** A cart running on a frictionless air track is propelled by a stream of water expelled by a gas-powered pressure washer stationed on the cart. There is a 1.00-m^3 water tank on the cart to provide the water for the pressure washer. The mass of the cart, including the operator riding it, the pressure washer with its fuel, and the empty water tank, is 400. kg. The water can be directed, by switching a valve, either backward or forward. In both directions, the pressure washer ejects 200. L of water per min with a muzzle velocity of 25.0 m/s.

a) If the cart starts from rest, after what time should the valve be switched from backward (forward thrust) to forward (backward thrust) for the cart to end up at rest?

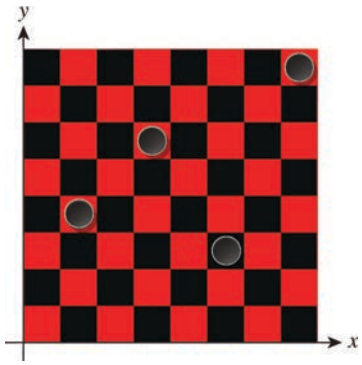
b) What is the mass of the cart at that time, and what is its velocity? (*Hint:* It is safe to neglect the decrease in mass due to the gas consumption of the gas-powered pressure washer!)

c) What is the thrust of this "rocket"?

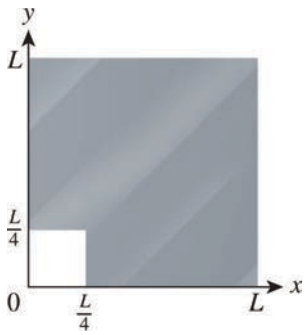
d) What is the acceleration of the cart immediately before the valve is switched?

Section 8.4

8.47 A 32.0-cm-by-32.0-cm checkerboard has a mass of 100. g. There are four 20.0-g checkers located on the checkerboard, as shown in the figure. Relative to the origin located at the bottom left corner of the checkerboard, where is the center of mass of the checkerboard-checkers system?



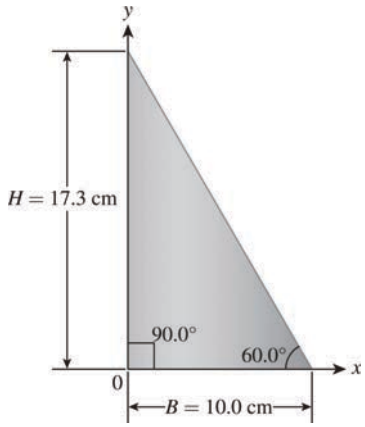
•**8.48** A uniform, square metal plate with side $L = 5.70$ cm and mass 0.205 kg is located with its lower left corner at $(x, y) = (0, 0)$, as shown in the figure. A square with side $L/4$ and its lower left edge located at $(x, y) = (0, 0)$, is removed from the plate. What is the distance from the origin of the center of mass of the remaining plate?



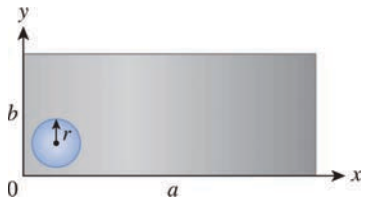
•**8.49** Find the x- and y-coordinates of the center of mass of the flat triangular plate of height $H = 17.3$ cm and base $B = 10.0$ cm shown in the figure.

•**8.50** The density of a 1.00-m long rod can be described by the linear density function $\lambda(x) = 100.\ \text{g/m} + 10.0x\ \text{g/m}^2$. One end of the rod is positioned at $x = 0$ and the other at $x = 1.00$ m.

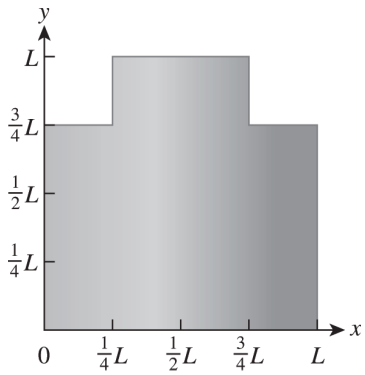
Determine (a) the total mass of the rod, and (b) the center-of-mass coordinate.



•**8.51** A thin rectangular plate of uniform area density $\sigma_1 = 1.05\ \text{kg/m}^2$ has a length $a = 0.600\ \text{m}$ and a width $b = 0.250\ \text{m}$. The lower left corner is placed at the origin, $(x, y) = (0, 0)$. A circular hole of radius $r = 0.0480\ \text{m}$ with center at $(x, y) = (0.068\ \text{m}, 0.068\ \text{m})$ is cut in the plate. The hole is plugged with a disk of the same radius that is composed of another material of uniform area density $\sigma_2 = 5.32\ \text{kg/m}^2$. What is the distance from the origin of the resulting plate's center of mass?



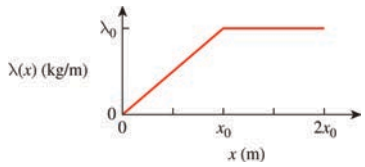
•**8.52** A uniform, square metal plate with side $L = 5.70\ \text{cm}$ and mass 0.205 kg is located with its lower left corner at $(x, y) = (0, 0)$, as shown in the figure. Two squares with side length $L/4$ are removed from the plate.



a) What is the x-coordinate of the center of mass?

b) What is the y-coordinate of the center of mass?

••8.53 The linear mass density, $\lambda(x)$, for a one-dimensional object is plotted in the graph. What is the location of the center of mass for this object?



Additional Exercises

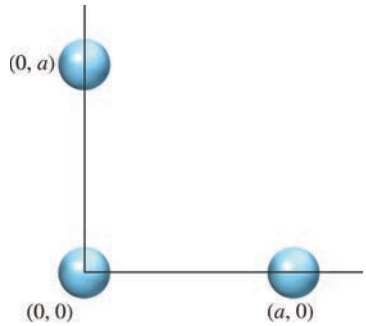
8.54 A 750.-kg cannon fires a 15.0-kg projectile with a speed of 250. m/s. with respect to the muzzle. The cannon is on wheels and can recoil with negligible friction. Just after the cannon fires the projectile, what is the speed of the projectile with respect to the ground?

8.55 The distance between a carbon atom ($m = 12.0$ u; 1 u = 1 atomic mass unit) and an oxygen atom ($m = 16.0$ u) in a carbon monoxide (CO) molecule is $1.13 \cdot 10^{-10}$ m. How far from the carbon atom is the center of mass of the molecule?

8.56 One method of detecting extrasolar planets involves looking for indirect evidence of a planet in the form of wobbling of its star about the star-planet system's center of mass. Assuming that the Solar System consisted mainly of the Sun and Jupiter, how much would the Sun wobble? That is, what back-and-forth distance would it move due to its rotation about the center of mass of the Sun-Jupiter system? How far from the center of the Sun is that center of mass?

8.57 The USS *Montana* is a massive battleship with a weight of 136,634,000 lb. It has twelve 16-inch guns, which are capable of firing 2700.-lb projectiles at a speed of 2300. ft/s. If the battleship fires three of these guns (in the same direction), what is the recoil velocity of the ship?

8.58 Three identical balls of mass m are placed in the configuration shown in the figure. Find the location of the center of mass.



8.59 Sam (61.0 kg) and Alice (44.0 kg) stand on an ice rink, providing them with a nearly frictionless surface to slide on. Sam gives Alice a push, causing her to slide away at a speed (with respect to the rink) of 1.20 m/s.

a) With what speed does Sam recoil?

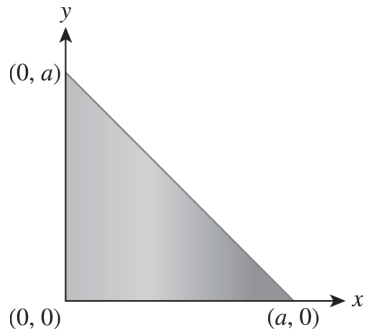
b) Calculate the change in the kinetic energy of the Sam-Alice system.

c) Energy cannot be created or destroyed. What is the source of the final kinetic energy of this system?

8.60 A baseball player uses a bat with mass m_{bat} to hit a ball with mass $m_{\text{ball.}}$ Right before he hits the ball, the bat's initial velocity is 35.0 m/s, and the ball's initial velocity is -30.0 m/s (the positive direction is along the positive x-axis). The bat and ball undergo a one-dimensional elastic collision. Find the speed of the ball after the collision. Assume that m_{bat} is much greater than $m_{\text{ball,}}$ so the center of mass of the two objects is essentially at the bat.

8.61 A student with a mass of 40.0 kg can throw a 5.00-kg ball with a relative speed of 10.0 m/s. The student is standing at rest on a cart of mass 10.0 kg that can move without friction. If the student throws the ball horizontally, what will the velocity of the ball with respect to the ground be?

•**8.62** Find the location of the center of mass of a two-dimensional sheet of constant density σ that has the shape of an isosceles triangle (see the figure).



•**8.63** A rocket consists of a payload of 4390.0 kg and $1.761 \cdot 10^5$ kg of fuel. Assume that the rocket starts from rest in outer space, accelerates to its final velocity, and then begins its trip. What is the speed at which the propellant must be expelled to make the trip from the Earth to the Moon, a distance of $3.82 \cdot 10^5$ km, in 7.00 h?

•**8.64** A 350.-kg cannon, sliding freely on a frictionless horizontal plane at a speed of 7.50 m/s, shoots a 15.0-kg cannonball at an angle of 55.0° above the horizontal. The velocity of the ball relative to the cannon is such that when the shot occurs, the cannon stops cold. What is the velocity of the ball relative to the cannon?

•**8.65** The Saturn V rocket, which was used to launch the *Apollo* spacecraft on their way to the Moon, has an initial mass $M_0 = 2.80 \cdot 10^6$ kg and a final mass $M_1 = 8.00 \cdot 10^5$ kg and burns fuel at a constant rate for 160. s. The speed of the exhaust relative to the rocket is about $v = 2700.$ m/s.

a) Find the upward acceleration of the rocket, as it lifts off the launch pad (while its mass is the initial mass).

b) Find the upward acceleration of the rocket, just as it finishes burning its fuel (when its mass is the final mass).

c) If the same rocket were fired in deep space, where there is negligible gravitational force, what would be the net change in the speed of the rocket during the time it was burning fuel?

•**8.66** Find the location of the center of mass for a one-dimensional rod of length L and of linear density $\boldsymbol{\lambda}(x) = cx$, where c is a constant. (*Hint:* You will need to calculate the mass in terms of c and L.)

•**8.67** Find the center of mass of a rectangular plate of length 20.0 cm and width 10.0 cm. The mass density varies linearly along the length. At one end, it is 5.00 g/cm^2; at the other end, it is 20.0 g/cm^2.

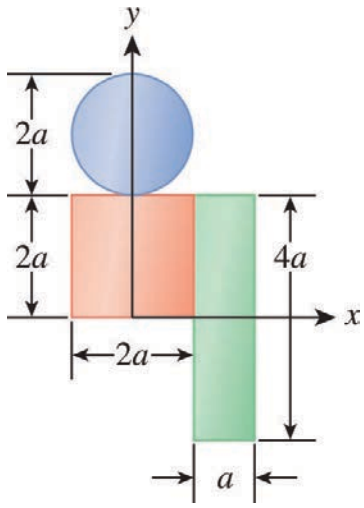
•**8.68** A uniform log of length 2.50 m has a mass of 91.0 kg and is floating in water. Standing on this log is a 72.0-kg man, located 22.0 cm from one end. On the other end is his daughter ($m = 20.0$ kg), standing 1.00 m from the end.

a) Find the center of mass of this system.

b) If the father jumps off the log backward away from his daughter ($v = 3.14$ m/s with respect to the water), what is the initial speed of log and child?

8.69 A sculptor has commissioned you to perform an engineering analysis of one of his works, which consists of regularly shaped metal

plates of uniform thickness and density, welded together as shown in the figure. Using the intersection of the two axes shown as the origin of the coordinate system, determine the Cartesian coordinates of the center of mass of this piece.



•**8.70** A jet aircraft is traveling at 223 m/s in horizontal flight. The engine takes in air at a rate of 80.0 kg/s and burns fuel at a rate of 3.00 kg/s. The exhaust gases are ejected at 600. m/s relative to the speed of the aircraft. Find the thrust of the jet engine.

•**8.71** A bucket is mounted on a skateboard, which rolls across a horizontal road with no friction. Rain is falling vertically into the bucket. The bucket is filled with water, and the total mass of the skateboard, bucket, and water is $M = 10.0$ kg. The rain enters the top of the bucket and simultaneously leaks out of a hole at the bottom of the bucket at equal rates of $\boldsymbol{\lambda} = 0.100$ kg/s. Initially, bucket and skateboard are moving at a speed of v_0. How long will it take before the speed is reduced by half?

•**8.72** A 1000.-kg cannon shoots a 30.0-kg shell at an angle of 25.0° above the horizontal and a speed of 500. m/s with respect to the ground. What is the recoil velocity of the cannon?

•**8.73** Two masses, $m_1 = 2.00$ kg and $m_2 = 3.00$ kg, are moving in the *xy*-plane. The velocity of their common center of mass and the velocity of mass 1 relative to mass 2 are given by the vectors $\vec{v}_{\text{cm}} = (-1.00, +2.40)$ m/s and $\vec{v}_{\text{rel}} = (+5.00, +1.00)$ m/s. Determine

a) the total momentum of the system,

b) the momentum of mass 1, and

c) the momentum of mass 2.

••**8.74** You are piloting a spacecraft whose total mass is 1000. kg and attempting to dock with a space station in deep space. Assume for simplicity that the station is stationary, that your spacecraft is moving at 1.00 m/s toward the station, and that both are perfectly aligned for docking. Your spacecraft has a small retro-rocket at its front end to slow its approach, which can burn fuel at a rate of 1.00 kg/s and with an exhaust velocity of 1.00. m/s relative to the rocket. Assume that your spacecraft has only 20.0 kg of fuel left and sufficient distance for docking.

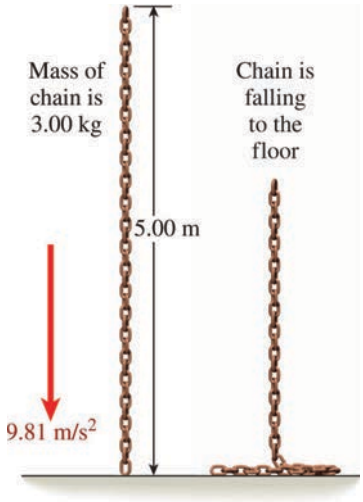
a) What is the initial thrust exerted on your spacecraft by the retro-rocket? What is the thrust's direction?

b) For safety in docking, NASA allows a maximum docking speed of 0.0200 m/s. Assuming you fire the retro-rocket from time $t = 0$ in one sustained burst, how much fuel (in kilograms) has to be burned to slow your spacecraft to this speed relative to the space station?

c) How long should you sustain the firing of the retro-rocket?

d) If the space station's mass is $5.00 \cdot 10^5$ kg (close to the value for the ISS), what is the final velocity of the station after the docking of your spacecraft, which arrives with a speed of 0.0200 m/s?

••**8.75** A chain whose mass is 3.00 kg and length is 5.00 m is held at one end so that the bottom end of the chain just touches the floor (see the figure). The top end of the chain is released. What is the force exerted by the chain on the floor just as the last link of the chain lands on the floor?



Mass of chain is 3.00 kg
Chain is falling to the floor
5.00 m
9.81 m/s²

MULTI-VERSION EXERCISES

8.76 An ion thruster mounted in a satellite uses electric forces to eject xenon ions with a speed of 21.45 km/s. The ion thruster produces a thrust of $1.187 \cdot 10^{-2}$ N. What is the rate of fuel consumption of the thruster?

8.77 An ion thruster mounted in a satellite uses electric forces to eject xenon ions with a speed of 23.75 km/s. The rate of fuel consumption of the thruster is $5.082 \cdot 10^{-7}$ kg/s. How much thrust is produced?

8.78 An ion thruster mounted in a satellite uses electric forces to eject xenon ions and produces a thrust of $1.229 \cdot 10^{-2}$ N. The rate of fuel consumption of the thruster is $4.718 \cdot 10^{-7}$ kg/s. With what speed are the xenon ions ejected from the thruster?

8.79 An ion thruster mounted in a satellite with mass 2149 kg (including 23.37 kg of fuel) uses electric forces to eject xenon ions with a speed of 28.33 km/s. If the ion thruster operates continuously while pointed in the same direction until it uses all of the fuel, what is the change in the speed of the satellite?

8.80 An ion thruster mounted in a satellite with mass 2161 kg (including fuel) uses electric forces to eject xenon ions with a speed of 20.61 km/s. The ion thruster operates continuously while pointed in the same direction until it uses all the available fuel. The change in the speed of the satellite is 236.4 m/s. How much fuel was available to the thruster?

8.81 An ion thruster mounted in a satellite uses electric forces to eject xenon ions with a speed of 22.91 km/s. The ion thruster operates continuously while pointed in the same direction until it

uses all 25.95 kg of the available fuel. The change in speed of the satellite is 275.0 m/s. What was the mass of the satellite and the fuel before the thruster started operating?

8.82 A 75.19-kg fisherman is sitting in his 28.09-kg fishing boat along with his 13.63-kg tackle box. The boat and its cargo are at rest near a dock. He throws the tackle box toward the dock with a speed of 2.911 m/s relative to the dock. What is the recoil speed of the fisherman and his boat?

8.83 A 77.49-kg fisherman is sitting in his 28.31-kg fishing boat along with his 14.27-kg tackle box. The boat and its cargo are at rest near a dock. He throws the tackle box toward the dock, and he and his boat recoil with a speed of 0.3516 m/s. With what speed, as seen from the dock, did the fishermen throw his tackle box?

8.84 A fisherman is sitting in his 28.51-kg fishing boat along with his 14.91-kg tackle box. The boat and its cargo are at rest near a dock. He throws the tackle box toward the dock, which it approaches with a speed of 3.303 m/s. The fisherman and his boat recoil with a speed of 0.4547 m/s. What is the mass of the fisherman?

8.85 A proton with mass $1.673 \cdot 10^{-27}$ kg is moving with a speed of $1.823 \cdot 10^{6}$ m/s toward an alpha particle with mass $6.645.10^{-27}$ kg, which is at rest. What is the speed of the center of mass of the proton-alpha particle system?

8.86 The center of mass of a proton with mass $1.673 \cdot 10^{-27}$ kg and an alpha particle with mass $6.645 \cdot 10^{-27}$ kg is moving with a speed of $5.509 \cdot 10^{5}$ m/s. What is the speed of the proton in the laboratory frame of reference, where the alpha particle is at rest?

In the Ames Research Center at Moffet Field, California, NASA operates a giant centrifuge, which is shown in Figure 9.1. By moving objects on a circular path, this centrifuge creates artificial gravity forces up to twenty times stronger than what we experience on Earth.

FIGURE 9.1 NASA's 20*g* centrifuge subjects astronauts and equipment to *g*-forces similar to those encountered during rocket launches.

NASA

In this chapter, we study circular motion and see how force is involved in making turns, which will let us understand how NASA's 20*g* centrifuge works. This discussion relies on concepts of force, velocity, and acceleration presented in Chapters 3 and 4. Chapter 10 will combine these ideas with some of the concepts from Chapters 5 through 8, such as energy and momentum. Much of what you will learn in these two chapters on circular motion and rotation is analogous to earlier material on linear motion, force, and energy. Because most objects do not travel in perfectly straight lines, the concepts of circular motion will be applied many times in later chapters.

What we will learn

- The motion of objects traveling in a circle rather than in a straight line can be described using coordinates based on radius and angle rather than Cartesian coordinates.
- There is a relationship between linear motion and circular motion.
- Circular motion can be described in terms of the angular coordinate, angular frequency, and period.
- An object undergoing circular motion can have angular velocity and angular acceleration.

9.1 Polar Coordinates

In Chapter 3, we discussed motion in two dimensions. In this chapter, we examine a special case of motion in a two-dimensional plane: motion of an object along the circumference of a circle. To be precise, we will only study circular motion of objects that we can consider to be point particles. In Chapter 10 on rotation, we will relax this condition and also examine extended bodies.

Circular motion is surprisingly common. Riding on a carousel or many other amusement park rides, such as those shown in Figure 9.2, qualifies as circular motion. Indy-style car racing also involves circular motion, as the cars alternate between moving along straight sections and half-circle segments of the track.

FIGURE 9.2 Circular motion in the horizontal and in the vertical plane.

Photographs in the Carol M. Highsmith Archive, Library of Congress, Prints & Photographs Division [LC-DIG-highsm-12678]

During an object's **circular motion,** its x- and y-coordinates change continuously, but the distance from the object to the center of the circular path stays the same. We can take advantage of this fact by using **polar coordinates** to study circular motion. Shown in Figure 9.3 is the position vector, $\vec{r}$, of an object in circular motion.

This vector changes as a function of time, but its tip always moves on the circumference of a circle. We can specify $\vec{r}$ by giving its x- and y-components. However, we can specify the same vector by giving two other numbers: the angle of $\vec{r}$ relative to the x-axis, θ, and the length of $\vec{r}$, $r = |\vec{r}|$ (Figure 9.3).

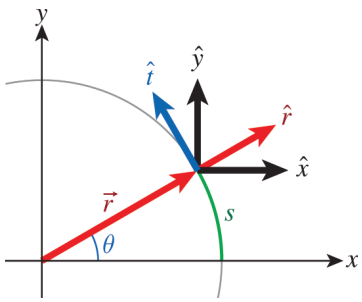

FIGURE 9.3 Polar coordinate system for circular motion.

Trigonometry provides the relationship between the Cartesian coordinates x and y and the polar coordinates θ and r:

$$r = \sqrt{x^2 + y^2} \tag{9.1}$$

$$\theta = \tan^{-1}(y/x). \tag{9.2}$$

The inverse transformation from polar to Cartesian coordinates is given by

$$x = r \cos \theta \tag{9.3}$$

$$y = r \sin \theta. \tag{9.4}$$

The major advantage of using polar coordinates for analyzing circular motion is that r never changes. It remains the same as long as the tip of the vector $\overrightarrow{r}$ moves along the circular path. Thus, we can reduce the description of two-dimensional motion on the circumference of a circle to a one-dimensional problem involving the angle θ.

Figure 9.3 also shows the unit vectors in the radial and tangential directions, $\hat{r}$ and $\hat{t}$, respectively. The angle between $\hat{r}$ and $\hat{x}$ is again the angle θ. Therefore, the Cartesian components of the radial unit vector can be written as follows (refer to Figure 9.4):

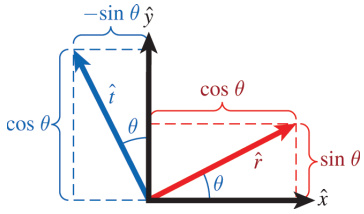

FIGURE 9.4
Relationship between the radial and tangential unit vectors shown in Figure 9.3, the Cartesian unit vectors, and the sine and cosine of the angle.

$$\hat{r} = \frac{x}{r}\hat{x} + \frac{y}{r}\hat{y} = (\cos\theta)\hat{x} + (\sin\theta)\hat{y} \equiv (\cos\theta, \sin\theta). \quad \textbf{(9.5)}$$

Similarly, we obtain the Cartesian components of the tangential unit vector (refer again to Figure 9.4 and note that the tangential and radial unit vectors are always perpendicular to each other; thus, the angle between the tangential unit vector and the y-axis is the same as the angle between the radial unit vector and the x-axis):

$$\hat{t} = \frac{-y}{r}\hat{x} + \frac{x}{r}\hat{y} = (-\sin\theta)\hat{x} + (\cos\theta)\hat{y} \equiv (-\sin\theta, \cos\theta). \text{ (}$$

(Note that the tangential unit vector is always denoted with a caret, $\hat{t}$, and can thus be readily distinguished from the time, t.) It is straightforward to verify that the radial and tangential unit vectors are perpendicular to each other by taking their scalar product:

$$\hat{r} \bullet \hat{t} = (\cos\theta, \sin\theta) \bullet (-\sin\theta, \cos\theta) = -\cos\theta \sin\theta + \sin\theta \cos$$

We can also verify that these two unit vectors have a length of 1, as required:

$$\hat{r} \bullet \hat{r} = (\cos\theta, \sin\theta) \bullet (\cos\theta, \sin\theta) = \cos^2\theta + \sin^2\theta = 1.$$
$$\hat{t} \bullet \hat{t} = (-\sin\theta, \cos\theta) \bullet (-\sin\theta, \cos\theta) = \sin^2\theta + \cos^2\theta = 1.$$

Finally, it is important to stress that, for circular motion, there is a major difference between the unit vectors for polar coordinates and those for Cartesian coordinates: The Cartesian unit vectors stay constant in time, while the radial and tangential unit vectors change their directions during the process of circular motion. This is because both of these vectors depend on the angle θ, which depends on the time for circular motion.

9.2 Angular Coordinates and Angular Displacement

Polar coordinates allow us to describe and analyze circular motion, where the distance to the origin, r, of the object in motion stays constant and the angle θ varies as a function of time, $\theta(t)$. As was already pointed out, the angle θ is measured relative to the positive x-axis. Any point on the positive x-axis has an angle $\theta = 0$. As the definition in equation 9.2 implies, a move in the counterclockwise direction away from the positive x-axis toward the positive y-axis results in positive values for the angle θ. Conversely, a clockwise move away from the positive x-axis toward the negative y-axis results in negative values of θ.

The two most commonly used units for angles are degrees ($^\circ$) and radians (rad). These units are defined such that the angle measured by one complete circle is 360°, which corresponds to 2π rad. Thus, the unit conversion between the two angular measures is

$$\theta(\text{degrees})\frac{\pi}{180} = \theta(\text{radians}) \Leftrightarrow \theta(\text{radians})\frac{180}{\pi} = \theta(\text{degrees})$$

$$1\,\text{rad} = \frac{180^\circ}{\pi} \approx 57.3^\circ.$$

Like the linear position x, the angle θ can have positive and negative values. However, θ is periodic; a complete turn around the circle (2π rad. or 360°) returns the coordinate for θ to the same point in space. Just as the linear displacement, Δx, is defined to be the difference between two positions, x_2 and x_1, the angular displacement, $\Delta\theta$, is the difference between two angles:

$$\Delta\theta = \theta_2 - \theta_1.$$

EXAMPLE 9.1 Locating a Point with Cartesian and Polar Coordinates

A point has a location given in Cartesian coordinates as (4,3), as shown in Figure 9.5.

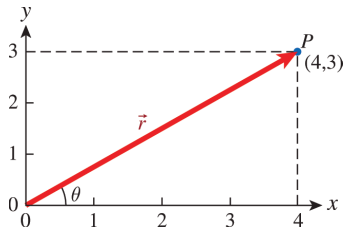

FIGURE 9.5 A point located at (4,3) in a Cartesian coordinate system.

PROBLEM

How do we represent the position of this point in polar coordinates?

SOLUTION

Using equation 9.1, we can calculate the radial coordinate:

$$r = \sqrt{x^2 + y^2} = \sqrt{4^2 + 3^2} = 5.$$

Using equation 9.2, we can calculate the angular coordinate:

$$\theta = \tan^{-1}(y/x) = \tan^{-1}(3/4) = 0.64\,\text{rad} = 37^\circ.$$

Therefore, we can express the position of point P in polar coordinates as $(r, \theta) = (5, 0.64\ \text{rad}) = (5, 37^\circ)$. Note that we can specify the same position by adding (any integral multiple of) 2π rad, or 360°, to θ:

$$(r, \theta) = (5,0.64\ \text{rad}) = (5, 37^\circ) = (5, 2\pi\ \text{rad} + 0.64\ \text{rad}) =$$

Arc Length

Figure 9.3 also shows (in green) the path on the circumference of the circle traveled by the tip of the vector $\vec{r}$ in going from an angle of zero to θ. This path is called the *arc length, s*. It is related to the radius and angle via

$$s = r\,\theta. \qquad \textbf{(9.7)}$$

Self-Test Opportunity 9.1

Use polar coordinates and calculus to show that the circumference of a circle with radius *R* is $2\pi R$.

For this relationship to work out numerically, the angle has to be measured in radians. The fact that the circumference of a circle is $2\pi r$ is a special case of equation 9.7 with $\theta = 2\pi$ rad, corresponding to one full turn around the circle. The arc length has the same unit as the radius.

For small angles, measuring a degree or less, the sine of the angle is approximately (to four significant figures) equal to the angle measured in radians. Because of this fact as well as the need to use equation 9.7 to solve problems, the preferred unit for angular coordinates is the radian. But the use of degrees is common, and this book uses both units.

Self-Test Opportunity 9.2

Use polar coordinates and calculus to show that the area of a circle with radius *R* is πR^2.

9.3 Angular Velocity, Angular Frequency, and Period

We have seen that the change of an object's linear coordinates in time is its velocity. Similarly, the change of an object's angular coordinate in time is its **angular velocity.** The average magnitude of the angular velocity is defined as

$$\overline{\omega} = \frac{\theta_2 - \theta_1}{t_2 - t_1} = \frac{\Delta\theta}{\Delta t}.$$

This definition uses the notation $\theta_1 \equiv \theta(t_1)$ and $\theta_2 \equiv \theta(t_2)$. The horizontal bar above the symbol ω for angular velocity again indicates a time average. By taking the limit of this expression as the time interval approaches zero, we find the instantaneous value of the magnitude of the angular velocity:

$$\omega = \lim_{\Delta t \to 0} \overline{\omega} = \lim_{\Delta t \to 0} \frac{\Delta\theta}{\Delta t} \equiv \frac{d\theta}{dt}. \qquad \textbf{(9.8)}$$

The most common unit of angular velocity is radians per second (rad/s); degrees per second is not generally used.

Angular velocity is a vector. Its direction is that of an axis through the center of the circular path and perpendicular to the plane of the circle. (This axis is a rotation axis, as we will discuss in more detail in Chapter 10.) This definition allows for two possibilities for the direction in which the vector $\vec{\omega}$ can point: up or down, parallel or antiparallel to the axis of rotation. A right-hand rule helps us decide which is the correct direction: When the fingers point in the direction of rotation along the circle's circumference, the thumb points in the direction of $\vec{\omega}$, as shown in Figure 9.6.

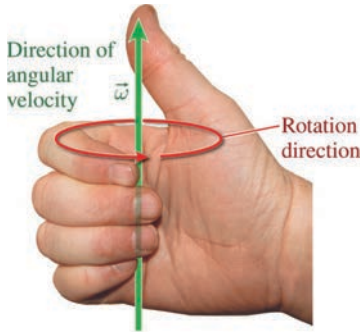

FIGURE 9.6 The right-hand rule for determining the direction of the angular velocity vector.

Mark Dierker/McGraw Hill

Angular velocity measures how fast the angle θ changes in time. Another quantity also specifies how fast this angle changes in time—the **frequency,** f. For example, the rpm number on the tachometer in your car indicates how many times per minute the engine cycles and thus specifies the frequency of engine revolution. Figure 9.7 shows a tachometer, with the units specified as $\text{rpm} \times 1000$; the engine hits the red line at 6000 revolutions per minute. Thus, the frequency, f, measures cycles per unit time, instead of radians per unit time as the angular velocity does. The frequency is related to the magnitude of the angular velocity, ω, by

FIGURE 9.7 The tachometer of a car measures the frequency (in cycles per minute) of revolutions of the engine.

W. Bauer and G. D. Westfall

$$f = \frac{\omega}{2\pi} \Leftrightarrow \omega = 2\pi f. \tag{9.9}$$

This relationship makes sense because one complete turn around a circle requires an angle change of 2π rad. (Be careful—both frequency and angular velocity have the same unit of inverse seconds and can be easily confused.)

Because the unit inverse second is used so widely, it was given its own name, the **hertz** (Hz), for the German physicist Heinrich Rudolf Hertz (1857–1894): $1\ \text{Hz} = 1\ \text{s}^{-1}$. The **period of rotation,** T, is defined as the inverse of the frequency:

$$T = \frac{1}{f}. \tag{9.10}$$

The period measures the time interval between two successive instances where the angle has the same value; that is, the time it

takes to pass once around the circle. The unit of the period is the same as that of time, the second (s). Given the relationships between period and frequency and between frequency and angular velocity, we also obtain

$$\omega = 2\pi f = \frac{2\pi}{T}. \qquad \textbf{(9.11)}$$

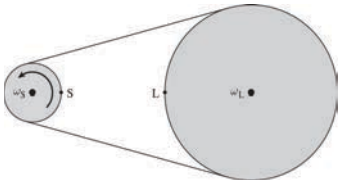
Concept Check 9.1

A small wheel and a large wheel are connected by a belt as shown in the figure. The small wheel is turned at a constant angular velocity ω_S. There is a point S on the rim of the small wheel and another point L on the rim of the large wheel. How do their speeds compare?

a) $v_S = v_L$

b) $v_S < v_L$

c) $v_S > v_L$



McGraw Hill

Angular Velocity and Linear Velocity

If we take the time derivative of the position vector, we obtain the linear velocity vector. To find the angular velocity, it is most convenient to write the radial position vector in Cartesian coordinates and take the time derivatives component by component:

$$\vec{r} = x\hat{x} + y\hat{y} = (x, y) = (r\cos\theta, r\sin\theta) = r(\cos\theta, \sin\theta) = r\hat{r}$$

$$\vec{v} = \frac{d\vec{r}}{dt} = \frac{d}{dt}(r\cos\theta, r\sin\theta) = \left(\frac{d}{dt}(r\cos\theta), \frac{d}{dt}(r\sin\theta)\right)$$

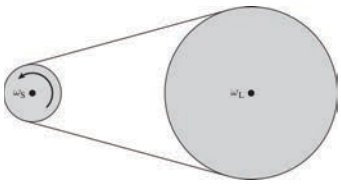
Concept Check 9.2

A small wheel and a large wheel are connected by a belt as shown in the figure. The small wheel is turned at a constant angular velocity ω_S. How does the magnitude of the angular velocity of the large wheel ω_L compare to ω_S ?

a) $\omega_S = \omega_L$

b) $\omega_S < \omega_L$

c) $\omega_S > \omega_L$



McGraw Hill

Now we can use the fact that, for motion along a circle, the distance r to the origin does not change in time but is constant. This results in

$$\vec{v} = \left(\frac{d}{dt}(r\cos\theta), \frac{d}{dt}(r\sin\theta)\right) = \left(r\frac{d}{dt}(\cos\theta), r\frac{d}{dt}(\sin\theta)\right)$$

$$\left(\quad , \frac{d\theta}{} \quad , \frac{d\theta}{} \right)$$

$$= \left(-r \sin\theta \frac{}{dt}, r \cos\theta \frac{}{dt} \right)$$

$$= (-\sin\theta, \cos\theta) r \frac{d\theta}{dt}.$$

Here we used the chain rule of differentiation in the next to last step and then factored out the common factor $r\, d\theta/dt$. We already know that the time derivative of the angle is the angular velocity (see equation 9.8). In addition, we recognize the vector $(-\sin\theta, \cos\theta)$ as the tangential unit vector (see equation 9.6). Thus, we have the relationship between angular and linear velocities for circular motion:

$$\vec{v} = r\omega\hat{t}. \qquad \textbf{(9.12)}$$

(Again, $\hat{t}$ is the symbol for the tangential unit vector and has no connection with the time, t!)

Because the velocity vector points in the direction of the tangent to the trajectory at any given time, it is always tangential to the circle's circumference, pointing in the direction of the motion, as shown in Figure 9.8. Thus, the velocity vector is always perpendicular to the position vector, which points in the radial direction. If two vectors are perpendicular to each other, their scalar product is zero. Thus, for circular motion, we always have

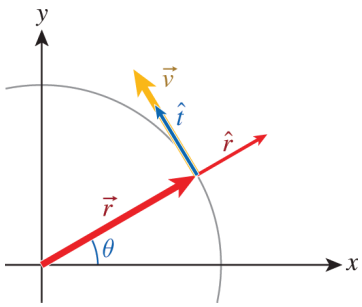


FIGURE 9.8 Linear velocity and coordinate vectors.

$$\vec{r} \bullet \vec{v} = (r\cos\theta, r\sin\theta) \bullet (-r\omega\sin\theta, r\omega\cos\theta) = 0.$$

Concept Check 9.3

A bicycle's wheels have a radius R. The bicycle is traveling with speed v. Which one of the following expressions describes the angular speed of the front tire?

a) $\omega = \frac{1}{2}Rv^2$

b) $\omega = \frac{1}{2}vR^2$

c) $\omega = R/v$

d) $\omega = Rv$

e) $\omega = v/R$

If we take the absolute values of the left- and right-hand sides of equation 9.12, we obtain an important relationship between the magnitudes of the linear and angular speeds for circular motion:

$$v = r\omega. \qquad \textbf{(9.13)}$$

Remember that this relationship holds only for the *magnitudes* of the linear and angular velocities. Their vectors point in different directions and, for uniform circular motion, are perpendicular to each other, with $\vec{\omega}$ pointing in the direction of the rotation axis and $\vec{v}$ tangential to the circle.

EXAMPLE 9.2 Revolution and Rotation of the Earth

PROBLEM

The Earth orbits around the Sun and also rotates on its pole-to-pole axis. What are the angular velocities, frequencies, and linear speeds of these motions?

SOLUTION

Any point on the surface of Earth moves in circular motion around the rotation axis (pole-to-pole), with a rotation period of 1 day. Expressed in seconds, this period is

$$T_{\text{Earth}} = 1\ \text{day} \cdot \frac{24\ \text{h}}{1\ \text{day}} \cdot \frac{3600\ \text{s}}{1\ \text{h}} = 8.64 \cdot 10^4\ \text{s}\,.$$

The Earth moves around the Sun on an elliptical path; the path is very close to circular, so let's treat the Earth's orbit as circular motion. The orbital period for the motion of the Earth around the Sun is 1 year. Expressing this period in seconds, we obtain

$$T_{\text{Sun}} = 1\ \text{year} \cdot \frac{365\ \text{days}}{1\ \text{year}} \cdot \frac{24\ \text{h}}{1\ \text{day}} \cdot \frac{3600\ \text{s}}{1\ \text{h}} = 3.15 \cdot 10^7\ \text{s}\,.$$

Both circular motions have constant angular velocity. Thus, we can use $T = 1/f$ and $\omega = 2\pi f$ to obtain the frequencies and angular velocities:

$$f_{\text{Earth}} = \frac{1}{T_{\text{Earth}}} = 1.16 \cdot 10^{-5}\ \text{Hz};\ \omega_{\text{Earth}} = 2\pi\, f_{\text{Earth}} = 7.2'$$

$$f_{\text{Sun}} = \frac{1}{T_{\text{Sun}}} = 3.17 \cdot 10^{-8}\ \text{Hz};\ \omega_{\text{Sun}} = 2\pi\, f_{\text{Sun}} = 1.99 \cdot 1$$

Note that the 24-hour period that we used as the length of a day is how long it takes the Sun to reach the same position in the sky. If we wanted to specify the frequencies and angular velocities to greater precision, we would have to use the sidereal day: Because

the Earth is also moving around the Sun during each day, the time it actually takes to complete one full rotation and bring the stars into the same position in the night sky is the sidereal day, which consists of 23 h, 56 min, and a little more than 4 s, or $86,164.09\,\text{s} = (1 - 1/366.242) \cdot 86,400\,\text{s}$. (We have used the fact that it takes a fraction of a day more than 365 to complete an orbit around the Sun—which is why leap years are necessary.)

Now let's find the linear velocity at which the Earth orbits the Sun. Because we are assuming circular motion, the relationship between the orbital speed and angular velocity is given by $v = r\omega$. To get our answer, we need to know the radius of the orbit. The radius of this orbit is the Earth-Sun distance, $r_{\text{Earth-Sun}} = 1.49.10^{11}\,\text{m}$. Therefore, the linear orbital speed—the speed with which the Earth moves around the Sun—is

$$v = r\omega = \left(1.49 \cdot 10^{11}\,\text{m}\right)\left(1.99 \cdot 10^{-7}\,\text{s}^{-1}\right) = 2.97.10^{4}\,\text{m/s}.$$

This is over 66,000 mph!

Now we want to find the speed of a point on the surface of the rotating Earth relative to the center of the Earth. We note that points at different latitudes have different distances to the axis of rotation, as shown in Figure 9.9. At the Equator, the radius of rotation is $r = R_{\text{Earth}} = 6380\,\text{km}$. Away from the Equator, the radius of rotation as a function of the latitude angle is $r = R_{\text{Earth}} \cos\vartheta$; see Figure 9.9. (The script theta, ϑ, is used for the latitude angles here in order to avoid confusion with θ, which is used for the motion in the circle.) In general, we obtain the following formula for the speed of rotation:

FIGURE 9.9 Earth's rotation axis is indicated by the vertical line. Points at different latitudes on the Earth's surface move at different speeds.

$$\begin{aligned} v &= \omega r = \omega R_{\text{Earth}} \cos\vartheta \\ &= \left(7.27 \cdot 10^{-5}\ \text{s}^{-1}\right)\left(6.38 \cdot 10^{6}\ \text{m}\right)(\cos\vartheta) \\ &= (464\ \text{m/s})(\cos\vartheta). \end{aligned}$$

At the poles, where $\vartheta = 90^\circ$, the rotation speed is zero; at the Equator, where $\vartheta = 0^\circ$, the speed is 464 m/s. Seattle, with $\vartheta = 47.5^\circ$, moves at $v = 313$ m/s, and Miami, with $\vartheta = 25.7^\circ$, has a speed of $v = 418$ m/s.

9.4 Angular and Centripetal Acceleration

The rate of change of an object's angular velocity is its **angular acceleration,** denoted by the Greek letter α. The definition of the magnitude of the angular acceleration is analogous to that for the linear acceleration. Its time average is defined as

$$\overline{\alpha} = \frac{\Delta\omega}{\Delta t}.$$

The instantaneous magnitude of the angular acceleration is obtained in the limit as the time interval approaches zero:

$$\alpha = \lim_{\Delta t \to 0} \overrightarrow{\alpha} = \lim_{\Delta t \to 0} \frac{\Delta\omega}{\Delta t} \equiv \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}. \quad \textbf{(9.14)}$$

Just as we related the linear velocity to the angular velocity, we can also relate the tangential acceleration to the angular acceleration. We start with the definition of the linear acceleration vector as the time derivative of the linear velocity vector. Then we substitute the expression for the linear velocity in circular motion from equation 9.12:

$$\overrightarrow{a}(t) = \frac{d}{dt}\overrightarrow{v}(t) = \frac{d}{dt}\left(v\hat{t}\right) = \left(\frac{dv}{dt}\right)\hat{t} + v\left(\frac{d\hat{t}}{dt}\right). \quad \textbf{(9.15)}$$

Concept Check 9.4

In Figure 9.8 the angular velocity vector points along the axis of rotation. The angular acceleration is the time derivative of the angular velocity. In what direction does the angular acceleration vector point?

a) in the radial direction

b) in the tangential direction

c) along the axis of rotation

d) perpendicular to the axis of rotation

In the last step here, we used the product rule of differentiation. Thus, the acceleration in circular motion has two components. The first part arises from the change in the magnitude of the velocity; this is the **tangential acceleration.** The second part is due to the fact that the velocity vector always points in the tangential direction and thus has to change its direction continuously as the tip of the radial position vector moves around the circle; this is the **radial acceleration.**

Let's look at the two components individually. First, we can calculate the time derivative of the linear speed, v, using the relationship between linear speed and angular speed in equation 9.13 and again invoking the product rule:

$$\frac{dv}{dt} = \frac{d}{dt}(r\omega) = \left(\frac{dr}{dt}\right)\omega + r\frac{d\omega}{dt}.$$

Concept Check 9.5

A horizontal table rotates counterclockwise (looking down from the top) with constant angular velocity. The components of the linear acceleration are the tangential acceleration a_t and the centripetal acceleration a_c. Select the correct statement with respect to the components of the acceleration at any point on the table.

a) a_t is zero and a_c is radially outward.

b) a_t is zero and a_c is radially inward.

c) a_t is zero and a_c is zero.

d) a_t is in the same direction as the linear velocity and a_c is radially outward.

e) a_t is in the same direction as the linear velocity and a_c is radially inward.

Because r is constant for circular motion, $dr/dt = 0$, and the first term in the sum on the right-hand side is zero. From equation 9.14, $d\omega/dt = \alpha$, and so the second term in the sum is equal to $r\alpha$. Thus, the change in speed is related to the angular acceleration by

$$\frac{dv}{dt} = r\alpha. \qquad \textbf{(9.16)}$$

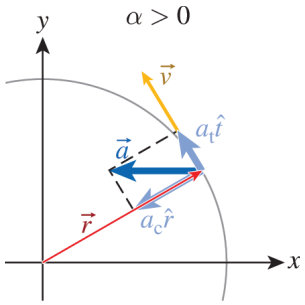
However, the acceleration vector of equation 9.15 also has a second component, which is proportional to the time derivative of the tangential unit vector. For this quantity, we find

$$\begin{aligned}\frac{d}{dt}\hat{t} &= \frac{d}{dt}(-\sin\theta,\ \cos\theta) = \left(\frac{d}{dt}(-\sin\theta),\ \frac{d}{dt}(\cos\theta)\right)\\ &= \left(-\cos\theta\frac{d\theta}{dt},\ -\sin\theta\frac{d\theta}{dt}\right) = -\frac{d\theta}{dt}(\cos\theta, \sin\theta)\\ &= -\omega\hat{r}.\end{aligned}$$

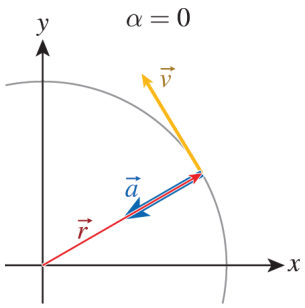
Therefore, we find that the time derivative of the tangential unit vector points in the direction opposite to that of the radial unit vector. With this result, we can finally write for the linear acceleration vector of equation 9.15:

$$\vec{a}(t) = r\alpha\hat{t} - v\omega\hat{r}. \qquad \textbf{(9.17)}$$

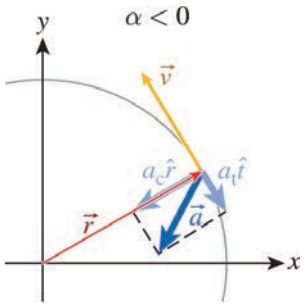
Again, for circular motion, the acceleration vector has two physical components (Figure 9.10): The first results from the change in speed and points in the tangential direction, and the second comes from the continuous change of direction of the velocity vector and points in the negative radial direction, toward the center of the circle. This second component is present even if the circular motion proceeds at constant speed. If the angular velocity is constant, the tangential angular acceleration is zero, but the velocity vector still changes direction continuously as the object moves in its circular path. The acceleration that changes the direction of the velocity vector without changing its magnitude is often called **centripetal acceleration** (*centripetal* means "center-seeking"), and it is directed in the inward radial direction. Thus, we can write equation 9.17 for the acceleration of an object in circular motion as the sum of the tangential acceleration and the centripetal acceleration:



(a)



(b)



(c)

FIGURE 9.10 Relationships among linear acceleration, centripetal acceleration, and angular acceleration for (a) increasing speed; (b) constant speed; and (c) decreasing speed.

$$\vec{a} = a_t\hat{t} - a_c\hat{r}. \tag{9.18}$$

The magnitude of the centripetal acceleration is

$$a_c = v\omega = \frac{v^2}{r} = \omega^2 r. \tag{9.19}$$

The first expression for the centripetal acceleration in equation 9.19 can be simply read off from equation 9.17 as the coefficient of the unit vector pointing in the negative radial direction. The second and third expressions for the centripetal acceleration then follow from the relationship between linear and angular speeds and the radius (equation 9.13).

For the magnitude of the acceleration in circular motion, we thus have, from equations 9.17 and 9.19,

$$a = \sqrt{a_t^2 + a_c^2} = \sqrt{(r\alpha)^2 + (r\omega^2)^2} = r\sqrt{\alpha^2 + \omega^4}. \quad (9.$$

EXAMPLE 9.3 Ultracentrifuge

One of the most important pieces of equipment in biomedical labs is the ultracentrifuge (Figure 9.11). It is used for separation of substances (such as colloids or proteins) consisting of *particles* of different masses through the process of sedimentation (more massive particles sink to the bottom). Instead of relying on the acceleration of gravity to accomplish sedimentation, an ultracentrifuge utilizes the centripetal acceleration from rapid rotation to speed up the process. Some ultracentrifuges can reach centripetal acceleration values of up to $10^6 g \left(g = 9.81 \text{ m/s}^2\right)$.

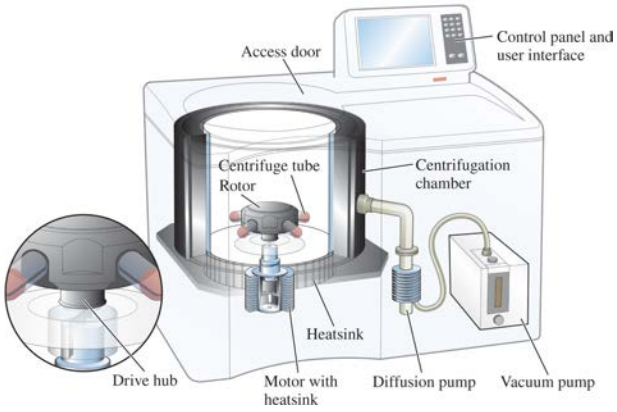


FIGURE 9.11 Cutaway diagram of an ultracentrifuge.

PROBLEM

If you want to generate 840,000g of centripetal acceleration in a sample rotating at a distance of 23.5 cm from the ultracentrifuge's rotation axis, what is the frequency you have to enter into the controls? What is the linear speed with which the sample is then moving?

SOLUTION

The centripetal acceleration is given by $a_c = \omega^2 r$, and the angular velocity is related to the frequency via equation 9.11:

$\omega = 2\pi f$. Thus, the relationship between the frequency and the centripetal acceleration is $a_c = (2\pi f)^2 r$, or

$$f = \frac{1}{2\pi}\sqrt{\frac{a_c}{r}} = \frac{1}{2\pi}\sqrt{\frac{(840,000)(9.81\ \text{m/s}^2)}{0.235\ \text{m}}} = 942\ \text{s}^{-}$$

For the linear speed of the sample inside the centrifuge, we then find

$$v = r\omega = 2\pi r f = 2\pi(0.235\ \text{m})\left(942\ \text{s}^{-1}\right) = 1.39\ \text{km/s}.$$

Other types of centrifuges called *gas centrifuges* are used in the process of uranium enrichment. In this process, the isotopes ^{235}U and ^{238}U (discussed in Chapter 40), which differ in mass by only slightly more than 1%, are separated. Natural uranium contains more than 99% of the harmless ^{238}U. But if uranium is enriched to contain more than 90% ^{235}U, it can be used for nuclear weapons. The gas centrifuges used in the enrichment process have to spin at approximately 100,000 rpm, which puts an incredible strain on the mechanisms and materials of these centrifuges and makes them very hard to design and manufacture. In order to impede proliferation of nuclear weapons, the design of these centrifuges is a closely guarded secret.

Self-Test Opportunity 9.3

The centripetal acceleration due to the Earth's rotation has a maximum value of approximately $g/300$. Can you determine the value of the centripetal acceleration due to the Earth's orbit around the Sun?

EXAMPLE 9.4 Centripetal Acceleration Due to Earth's Rotation

Because the Earth rotates, points on its surface move with a rotational velocity, and it is interesting to compute the corresponding centripetal acceleration. This acceleration can slightly alter the commonly stated value of the acceleration due to gravity at the surface of Earth.

We can insert the data for the Earth into equation 9.19 to find the magnitude of the centripetal acceleration:

$$\begin{aligned} a_{\mathrm{c}} &= \omega^2 r = \omega^2 R_{\mathrm{Earth}} \cos \vartheta \\ &= \left(7.27 \cdot 10^{-5}\ \mathrm{s}^{-1}\right)^2 \left(6.38 \cdot 10^{6}\ \mathrm{m}\right) (\cos \vartheta) \\ &= \left(0.034\ \mathrm{m/s^2}\right) (\cos \vartheta). \end{aligned}$$

Here we have used the same notation as in Example 9.2, with ϑ indicating the latitude angle relative to the Equator. Our result shows that the centripetal acceleration due to the Earth's rotation changes the effective gravitational acceleration observed on the surface of Earth by a factor ranging between 0.34 percent (at the Equator) and zero (at the poles). Using Seattle and Miami as examples, we obtain a centripetal acceleration of $0.02\ \mathrm{m/s^2}$ for Seattle and $0.03\ \mathrm{m/s^2}$ for Miami. These values are relatively small compared to the quoted value for the acceleration of gravity, $9.81\ \mathrm{m/s^2}$, but are not always negligible.

Concept Check 9.6

The rotation of the Earth on its axis creates a centripetal acceleration at the surface of the Earth. Suppose you were standing on the Equator and the Earth stopped rotating. When the Earth stopped, you would

a) feel slightly lighter than before.

b) feel slightly heavier than before.

c) fly off the surface of the Earth.

d) not be able to tell whether the Earth was still rotating.

9.5 Centripetal Force

The centripetal force, $\overrightarrow{F_c}$, is not another fundamental force of nature but is simply the net inward force needed to provide the centripetal acceleration necessary for circular motion. It has to point inward, toward the circle's center. Its magnitude is the product of the mass of the object and the centripetal acceleration required to force it onto a circular path:

$$F_c = ma_c = mv\omega = m\frac{v^2}{r} = m\omega^2 r. \qquad \textbf{(9.21)}$$

To arrive at equation 9.21, we simply wrote the centripetal acceleration in terms of the linear velocity v, the angular velocity ω, and the radius r, as in equation 9.19, and multiplied it by the mass of the object forced onto a circular path by the centripetal force.

Page 271

Concept Check 9.7

You are sitting on a carousel, which is in motion. Where should you sit so that the largest possible centripetal force is acting on you?

a) close to the outer edge

b) close to the center

c) in the middle

d) The force is the same everywhere.

Figure 9.12 shows a top view of a spinning table with three identical (except for color) poker chips on it. The black chip is located

close to the center, the red chip close to the outer edge, and the blue chip in the middle between them. If we spin the table slowly as in part (a), all three chips are in circular motion. In this case, the static friction force between the table and the chips provides the centripetal force required to keep the chips in circular motion. In parts (b), (c), and (d), the table is spinning progressively faster. A higher angular velocity means a larger centripetal force, according to equation 9.21. The chips slide when the friction force is not large enough to provide the centripetal force needed. As you can see, the outermost chip slides off first, and the innermost chip last. This clearly indicates that, for a given angular velocity, the centripetal force increases with the distance from the center. Equation 9.21 in the form $F_c = m\omega^2 r$ can explain this observed behavior. All points on the surface of the spinning table have the same angular velocity, ω, because all of them take the same time to complete one revolution. Thus, for the three poker chips, the centripetal force is proportional to the distance from the center, explaining why the red chip slides off first and the black chip slides off last.

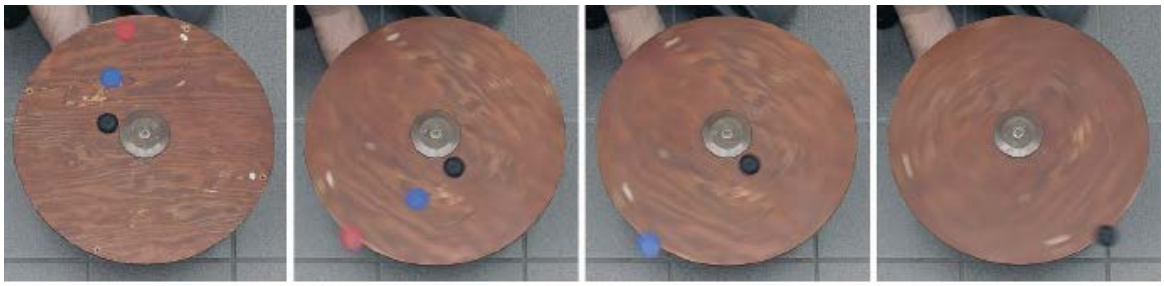

FIGURE 9.12 Poker chips on a spinning table. Shown from left to right are the initial positions of the chips and the moments when the three chips slide off during the process of circular motion.

W. Bauer and G. D. Westfall

Conical Pendulum

Figure 9.13 is a picture of the Wave Swinger, a ride at an amusement park. The riders sit in seats that are suspended from a solid disk by long chains. At the beginning of the ride, the chains hang straight down, but as the ride starts to rotate, the chains form an angle φ with the vertical, as you can see. This angle is independent of the mass of the rider and depends only on the angular velocity of the circular motion. How can we find the value of this angle in terms of that velocity?

FIGURE 9.13 Wave Swinger at an amusement park.

W. Bauer and G. D. Westfall

In order to gain this understanding, we consider a similar, but somewhat simpler situation: a mass suspended from the ceiling by a string of length ℓ and performing circular motion such that the angle between the string and the vertical is φ. The string outlines the surface of a cone, which is why this setup is called a *conical pendulum;* see Figure 9.14.

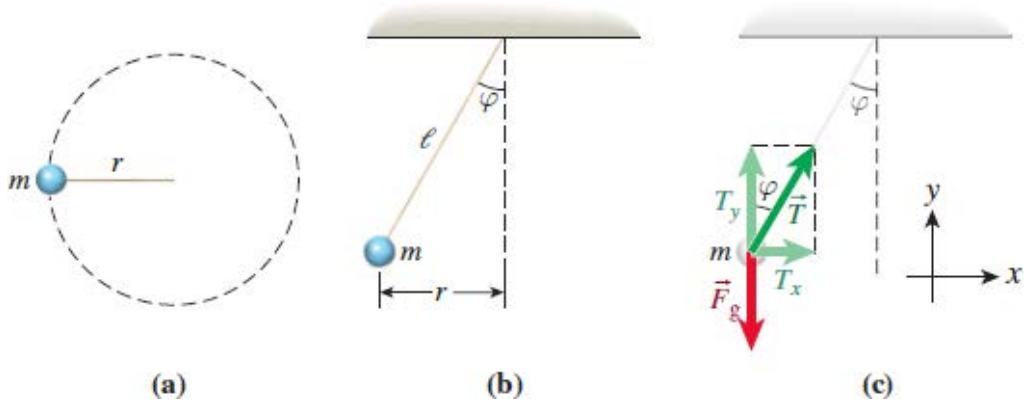

FIGURE 9.14 Conical pendulum: (a) top view, with the circular path of the mass indicated by the dashed line; (b) side view; (c) free-body diagram.

Figure 9.14c shows a free-body diagram for the mass. There are only two forces acting on it. Acting vertically downward is the force of gravity, $\vec{F}_g$, indicated by the red arrow in the free-body diagram; as usual, its magnitude is mg. The only other force acting on the mass is the string tension, $\vec{T}$, which acts along the direction of the string at an angle φ with the vertical. This string tension is broken down into its x- and y-components $(T_x = T\sin\varphi, T_y = T\cos\varphi)$. There is no motion in the vertical direction; therefore, we have to have zero net force in that direction, $F_{\text{net},y} = T\cos\varphi - mg = 0$, leading to

$$T\cos\varphi = mg.$$

Self-Test Opportunity 9.4

Sketch a graph of the string tension as a function of the angle φ.

In the horizontal direction, the horizontal component of the string tension is the only force component; it provides the centripetal force. Newton's Second Law, $F_{\text{net},x} = F_c = ma_c$, then yields

$$T\sin\varphi = mr\omega^2.$$

As you can see from Figure 9.14b, the radius of the circular motion is given by $r = \ell \sin \varphi$. Using this relationship, we find the string tension in terms of the angular velocity:

$$T = m\ell\omega^2. \tag{9.22}$$

We have just seen that $T \cos \varphi = mg$, and we can substitute the expression for T from equation 9.22 into this equation to get

$$\begin{aligned} \left(m\ell\omega^2\right)(\cos\varphi) &= mg \\ \omega^2 &= \frac{g}{\ell\,\cos\varphi} \\ \omega &= \sqrt{\frac{\mathrm{g}}{\ell\cos\varphi}}. \end{aligned} \tag{9.23}$$

Concept Check 9.8

A certain angular velocity, ω_0, of a conical pendulum results in an angle φ_0. If this conical pendulum were taken to the Moon, where the gravitational acceleration is a sixth of that on Earth, how would one have to adjust the angular velocity to obtain the same angle φ_0?

a) $\omega_{\text{Moon}} = 6\omega_0$

b) $\omega_{\text{Moon}} = \sqrt{6}\omega_0$

c) $\omega_{\text{Moon}} = \omega_0$

d) $\omega_{\text{Moon}} = \omega_0/\sqrt{6}$

e) $\omega_{\text{Moon}} = \omega_0/6$

The mass cancels out, which explains why all the chains in Figure 9.13 have the same angle with the vertical. Clearly, there is a unique and interesting relationship between the angle of the conical pendulum and its angular velocity. As the angle φ approaches zero, the angular velocity does not approach zero but rather some finite minimum value, $\sqrt{g/\ell}$. (We will gain a deeper understanding of this result in Chapter 14, when we study pendulum motion.) In the limit where the angle φ approaches 90°, ω becomes infinite.

SOLVED PROBLEM 9.1 Analysis of a Roller Coaster

Perhaps the biggest thrill to be had at an amusement park is on a roller coaster with a vertical loop in it (Figure 9.15), where passengers feel almost weightless at the top of the loop.

FIGURE 9.15 Modern roller coaster with a vertical loop.

Perry Mastrocito/Corbis/Getty Images

PROBLEM

Suppose the vertical loop has a radius of 5.00 m. What does the linear speed of the roller coaster have to be at the top of the loop for the passengers to feel weightless? (Assume that friction between roller coaster and rails can be neglected.)

SOLUTION

THINK

A person feels weightless when there is no supporting force, from a seat or a restraint, acting to counter his or her weight. For a

person to feel weightless at the top of the loop, no normal force can be acting on him or her at this point.

SKETCH

The free-body diagrams in Figure 9.16 may help to conceptualize the situation. The force of gravity and the normal force acting on a passenger in the roller coaster at the top of the loop are shown in Figure 9.16a. The sum of these two forces is the net force, which has to equal the centripetal force in circular motion. If the net force (centripetal force here) is equal to the gravitational force, then the normal force is zero, and the passenger feels weightless. This situation is illustrated in Figure 9.16b.

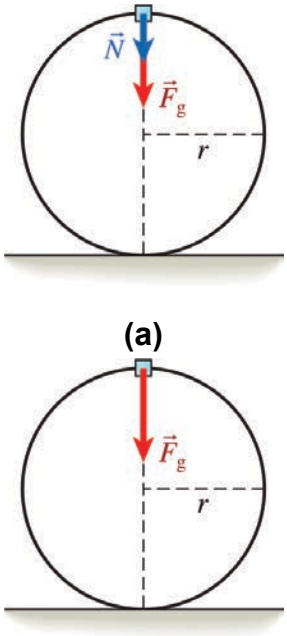

FIGURE 9.16 (a) Free-body diagram for a passenger at the top of the vertical loop of a roller coaster. (b) Condition for the feeling of weightlessness.

RESEARCH

We have just stated that the net force is equal to the centripetal force and that the net force is the sum of the normal force and the force of gravity:

$$\vec{F}_{\text{c}} = \vec{F}_{\text{net}} = \vec{F}_{\text{g}} + \vec{N}.$$

For the feeling of weightlessness at the top of the loop, we need $\vec{N} = 0$, and thus

$$\vec{F}_{\text{c}} = \vec{F}_{\text{g}} \Rightarrow F_{\text{c}} = F_{\text{g}}. \qquad \text{(i)}$$

As always, we have $F_{\text{g}} = mg$. For the magnitude of the centripetal force, we use equation 9.21:

$$F_{\text{c}} = ma_{\text{c}} = m\frac{v^2}{r}.$$

SIMPLIFY

After substituting the expressions for the centripetal and the gravitational forces into equation (i), we solve for the linear speed at the top of the loop:

$$F_{\text{c}} = F_{\text{g}} \Rightarrow m\frac{v_{\text{top}}^2}{r} = mg \Rightarrow v_{\text{top}} = \sqrt{rg}.$$

CALCULATE

Using $g = 9.81\ \text{m/s}^2$ and the value of $5.00\ \text{m}$ given for the radius, we obtain

$$v_{\text{top}} = \sqrt{(5.00\ \text{m})(9.81\ \text{m/s}^2)} = 7.00357\ \text{m/s}.$$

ROUND

Rounding our result to three-digit precision, we have

$$v_{\text{top}} = 7.00 \text{ m/s}.$$

DOUBLE-CHECK

Obviously, our answer passes the simplest check in that the units are those of speed, meters per second. The formula for the linear speed at the top, $v_{\text{top}} = \sqrt{rg}$, indicates that a larger radius necessitates a higher speed, which seems plausible.

Is 7.00 m/s for the speed at the top reasonable? Converting this value gives 15.7 mph, which seems fairly slow for a ride that is typically experienced as tremendously fast. But keep in mind that this is the minimum speed needed at the top of the loop, and the operators of the rides do not want to get too close to this value.

Let's go a step further and calculate the velocity vectors at the 3 o'clock and 9 o'clock positions on the loop, assuming that the roller coaster moves counterclockwise around the loop. The directions of the velocity vectors for circular motion are always tangential to the circle, as shown in Figure 9.17.

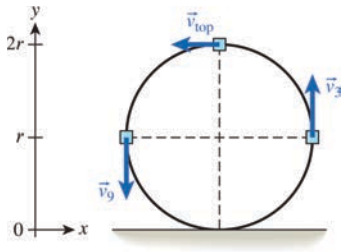

FIGURE 9.17
Directions of the velocity vectors at several points along the vertical roller-coaster loop.

How do we obtain the magnitudes of the velocities v_3 (at 3 o'clock) and v_9 (at 9 o'clock)? First, recall from Chapter 6 that the total energy is the sum of kinetic and potential energies, $E = K + U$, that the kinetic energy is $K = \frac{1}{2}mv^2$, and that the

gravitational potential energy is proportional to the height above ground, $U = mgy$. In Figure 9.17, the coordinate system is placed so that the zero of the y-axis is at the bottom of the loop. We then can write the equation for the conservation of mechanical energy assuming no nonconservative forces are acting:

$$E = K_3 + U_3 = K_{\text{top}} + U_{\text{top}} = K_9 + U_9 \Rightarrow$$
$$\frac{1}{2}mv_3^2 + mgy_3 = \frac{1}{2}mv_{\text{top}}^2 + mgy_{\text{top}} = \frac{1}{2}mv_9^2 + mgy_9. \quad \text{(ii}$$

We can see from the figure that the y-coordinates and therefore the potential energies are the same at the 3 o'clock and 9 o'clock positions; therefore, the kinetic energies at both points have to be the same. Consequently, the absolute values of the speeds at both points are the same: $v_3 = v_9$. Solving equation (ii) for v_3, we obtain

$$\frac{1}{2}mv_3^2 + mgy_3 = \frac{1}{2}mv_{\text{top}}^2 + mgy_{\text{top}} \Rightarrow$$
$$\frac{1}{2}v_3^2 + gy_3 = \frac{1}{2}v_{\text{top}}^2 + gy_{\text{top}} \Rightarrow$$
$$v_3 = \sqrt{v_{\text{top}}^2 + 2g(y_{\text{top}} - y_3)}.$$

Again, the mass cancels out. Further, only the difference in the y-coordinates enters into this formula for v_3; therefore, the choice of the origin of the coordinate system is irrelevant. The difference in the y-coordinates between the two points is $y_{\text{top}} - y_3 = r$. Inserting the given value of $r = 5.00\ \text{m}$ and the result $v_{\text{top}} = 7.00\ \text{m/s}$ that we found previously, we see that the speed at the 3 o'clock and at the 9 o'clock positions in the loop is

$$v_3 = \sqrt{(7.00\ \text{m/s})^2 + 2(9.81\ \text{m/s}^2)(5.00\ \text{m})} = 12.1\ \text{m/s}.$$

Concept Check 9.9

When you go through a vertical loop on a high-speed roller coaster, what keeps you in your seat?

a) centrifugal force

b) the normal force from the track

c) the force of gravity

d) the force of friction

e) the force exerted by the seat belt

Self-Test Opportunity 9.5

What speed must the roller coaster of Solved Problem 9.1 have at the top of the loop to accomplish the same feeling of weightlessness if the radius of the loop is doubled?

As you can see from this discussion, practically any force can act as the centripetal force. It was the force of static friction for the poker chips on the rotating table and the horizontal component of the tension in the string for the conical pendulum. But it can also be the gravitational force, which forces planets into (almost) circular orbits around the Sun (see Chapter 12), the Coulomb force acting on the electrons in atoms (see Chapter 21), or the normal force from a wall (see the following solved problem).

SOLVED PROBLEM 9.2 Carnival Ride

PROBLEM

One of the rides found at carnivals is a rotating cylinder, as shown in Figure 9.18. The riders step inside the vertical cylinder and stand with their backs against the curved wall. The cylinder spins very rapidly, and at some angular velocity, the floor is pulled away. The thrill-seekers now hang like flies on the wall. (The cylinder in Figure 9.18 is lifted up and tilted after the ride reaches its operating angular velocity, but we will not deal with this additional complication.) If the radius of the cylinder is $r = 2.10$ m, the rotation axis of the cylinder remains vertical, and the coefficient of static friction between the people and the wall is $\mu_s = 0.390$, what is the minimum angular velocity, ω, at which the floor can be withdrawn?

FIGURE 9.18 A carnival ride consisting of a rotating cylinder.

Gordana Sermek/Shutterstock

SOLUTION

THINK

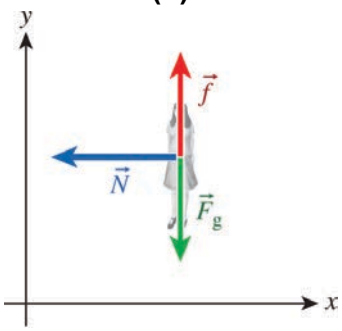
When the floor drops away, the magnitude of the force of static friction between a rider and the wall of the rotating cylinder must equal the magnitude of the force of gravity acting on the rider. The static friction between the rider and the wall depends on the normal force being exerted on the rider and the coefficient of static friction. As the cylinder spins faster, the normal force (which acts as the centripetal force) being exerted on the rider

increases. At a certain angular velocity, the maximum magnitude of the force of static friction will equal the magnitude of the force of gravity. That angular velocity is the minimum angular velocity at which the floor can be withdrawn.

SKETCH

A top view of the rotating cylinder is shown in Figure 9.19a. The free-body diagram for one of the riders is shown in Figure 9.19b, where the rotation axis is assumed to be the y-axis. In this sketch, $\vec{f}$ is the force of static friction, $\vec{N}$ is the normal force exerted on the rider of mass m by the wall of the cylinder, and $\vec{F}_g$ is the force of gravity acting on the rider.

(a)



(b)

FIGURE 9.19 (a) Top view of the rotating cylinder of a carnival ride. (b) Free-body diagram for one of the riders.

RESEARCH

At the minimum angular velocity required to keep the rider from falling, the magnitude of the force of static friction between the rider and the wall is equal to the magnitude of the force of gravity acting on the rider. To analyze these forces, we start with the free-body diagram shown in Figure 9.19b. In the free-body diagram, the x-direction is along the radius of the cylinder, and the y-direction is vertical. In the x-direction, the normal force exerted by the wall on the rider provides the centripetal force that makes the rider move in a circle:

$$F_{\mathrm{c}} = N. \tag{i}$$

In the y-direction, the thrill-seeking rider sticks to the wall only if the upward force of static friction between the rider and wall balances the downward force of gravity. The force of gravity on the rider is his or her weight, so we can write

$$f = F_{\mathrm{g}} = mg. \tag{ii}$$

We know that the centripetal force is given by

$$F_{\mathrm{c}} = mr\omega^2, \tag{iii}$$

and the force of static friction is given by

$$f \leq f_{\mathrm{max}} = \mu_{\mathrm{s}} N. \tag{iv}$$

SIMPLIFY

We can combine equations (ii) and (iv) to obtain

$$mg \leq \mu_{\mathrm{s}} N. \tag{v}$$

Substituting for F_c from equation (i) into (iii), we find

$$N = mr\omega^2. \qquad \text{(vi)}$$

Combining equations (v) and (vi), we have

$$mg \leq \mu_s mr\omega^2,$$

which we can solve for ω:

$$\omega \geq \sqrt{\frac{g}{\mu_s r}}.$$

Thus, the minimum value of the angular velocity is given by

$$\omega_{\text{min}} = \sqrt{\frac{g}{\mu_s r}}.$$

Note that the mass of the rider canceled out. This is crucial since people of different masses want to ride at the same time!

CALCULATE

Putting in the numerical values, we find

$$\omega_{\text{min}} = \sqrt{\frac{g}{\mu_s r}} = \sqrt{\frac{9.81\ \text{m/s}^2}{(0.390)(2.10\ \text{m})}} = 3.46093\ \text{rad/s}.$$

ROUND

Expressing our result to the three significant figures that the numbers in the problem statement had gives

$$\omega_{\text{min}} = 3.46\ \text{rad/s}.$$

DOUBLE-CHECK

To double-check, let's express our result for the angular velocity in revolutions per minute (rpm):

$$3.46\frac{\text{rad}}{\text{s}} = \left(3.46\frac{\text{rad}}{\text{s}}\right)\left(\frac{60\text{ s}}{1\text{ min}}\right)\left(\frac{1\text{ rev}}{2\pi\text{ rad}}\right) = 33\text{ rpm}.$$

An angular velocity of 33 rpm for the rotating cylinder seems reasonable, because this means that it completes almost one full turn every 2 s. If you have ever been on one of these rides or watched one, you know that the answer is in the right ballpark.

Note that the coefficient of friction, μ_s, between the clothing of the rider and the wall is not identical in all cases. Our formula, $\omega_{\text{min}} = \sqrt{g/(\mu_s r)}$, indicates that a smaller coefficient of friction necessitates a larger angular velocity. Designers of this kind of ride need to make sure that they allow for the smallest coefficient of friction that can be expected to occur. Obviously, they want to have a somewhat sticky contact surface on the wall of the ride, just to make sure!

One last point to check: $\omega_{\text{min}} = \sqrt{g/(\mu_s r)}$ indicates that the minimum angular velocity required will decrease as a function of the radius of the cylinder. The example of the poker chips on the spinning table presented earlier in this section established that the centripetal force increases with radial distance, which is consistent with this result.

Is There a Centrifugal Force?

This is a good time to clarify an important point regarding the direction of the force responsible for circular motion. You often hear people talking about centrifugal (or "center-fleeing," in the radial outward direction) acceleration or centrifugal force (mass times acceleration). You can experience the sensation of seemingly being pulled outward on many rotating amusement park rides, like the one considered in Solved Problem 9.2. This sensation is due to your body's inertia, which resists the centripetal acceleration toward the center. Thus, you feel a seemingly outward-pointing force—the centrifugal force. Keep in mind that this perception is due to your body moving in an accelerated reference frame; there is no centrifugal force. The real force that acts on your body and forces it to move on a circular path is the centripetal force, and it points inward. Nevertheless, the effect in the rotating frame is the same as that of a force pointing in the outward direction. This is why NASA's centrifuge, shown in Figure 9.1, can simulate up to 20g of gravitational acceleration for astronauts and equipment. The effect of an outward-pointing force felt by an observer inside the centrifuge is real, but it is caused by the observer's experiencing a continuous acceleration in the inward direction. Chapter 35 on relativity will continue this discussion.

Concept Check 9.10

At the top of a vertical loop in a roller coaster, what condition must be met for the car to stay on the track?

a) The centrifugal force acting on the car must equal the centripetal force.

b) The normal force exerted by the track on the car must be equal to the force of gravity.

c) The normal force exerted by the track on the car must be in the direction opposite to the force of gravity.

d) The centripetal force required to keep the car moving in a circle must be equal to or greater than the force of gravity.

e) The normal force exerted by the track on the car must be zero.

You have also experienced a similar effect in straight-line motion. When you are sitting in your car at rest and then step on the gas pedal, you feel as if you are being pressed back into your seat. This sensation of a force that presses you in the backward direction also comes from the inertia of your body, which is accelerated forward by your car. Both of these sensations of forces acting on your body—the "centrifugal" force and the force "pushing" you into the seat—are the result of your body experiencing an acceleration in the opposite direction and putting up resistance, inertia, against this acceleration.

9.6 Circular and Linear Motion

Table 9.1 summarizes the relationships between linear and angular quantities for circular motion. The relationships shown in the table relate the angular quantities (θ, ω and α) to the linear quantities (s, v, and a). The radius r of the circular path is constant and provides the connection between the two sets of quantities. (In Chapter 10, the rotational counterparts to mass, kinetic energy, momentum, and force will be added to this list.)

Table 9.1 Comparison of Kinematical Variables for Circular Motion

Quantity	Linear	Angular	Relationship
Displacement	s	θ	$s = r\theta$
Velocity	v	ω	$v = r\omega$
Acceleration	a	α	$a_t = r\alpha$
			$a_c = r\omega^2$
			$\vec{a} = r\alpha\hat{t} - r\omega^2\hat{r}$

As we have just seen, there is a formal correspondence between motion on a straight line with constant velocity and circular motion with constant angular velocity. However, there is one big difference. As we saw in Section 3.6 on relative motion, you cannot always distinguish between moving with constant velocity in a straight line and being at rest. This is because the origin of the coordinate system can be placed at any point—even a point that moves with constant velocity. The physics of translational motion does not change under this Galilean transformation. In contrast, in circular motion, you are always moving on a circular path with a well-defined center. Experiencing the “centrifugal” force is then a sure sign of circular

motion, and the strength of that force is a measure of the magnitude of angular velocity. You may argue that you are in constant circular motion around the center of the Earth, around the center of the Solar System, and around the center of the Milky Way Galaxy, but you do not feel the effects of those circular motions. True, but the very small magnitudes of the angular velocities involved in these motions cause their perceived effects to be negligible.

Constant Angular Acceleration

Chapter 2 discussed at some length the special case of constant acceleration. Under this assumption, we derived five equations that proved useful in solving all kinds of problems. For ease of reference, here are those five equations of linear motion with constant acceleration:

$$\begin{aligned}
&\text{(i)} && x = x_0 + v_{xo}t + \tfrac{1}{2}a_x t^2 \\
&\text{(ii)} && x = x_0 + \overline{v}_x t \\
&\text{(iii)} && v_x = v_{x0} + a_x t \\
&\text{(iv)} && \overline{v}_x = \tfrac{1}{2}(v_x + v_{x0}) \\
&\text{(v)} && v_x^2 = v_{x0}^2 + 2a_x(x - x_0).
\end{aligned}$$

Now we'll take the same steps as in Chapter 2 to derive the equivalent equations for constant angular acceleration. We start with equation 9.14 and integrate, using the usual notation convention of $\omega_0 \equiv \omega(t_0)$:

$$\alpha(t) = \frac{d\omega}{dt} \Rightarrow$$

$$\int_{t_0}^{t} \alpha(t')\,dt' = \int_{t_0}^{t} \frac{d\omega(t')}{dt'}\,dt' = \omega(t) - \omega(t_0) \Rightarrow$$

$$\omega(t) = \omega_0 + \int_{t_0}^{t} \alpha(t')\,dt'.$$

This relationship is the inverse of equation 9.14 and holds in general. If we assume the angular acceleration, α, is constant in time, we can evaluate the integral and obtain

$$\omega(t) = \omega_0 + \alpha \int_0^t dt' = \omega_0 + \alpha t. \qquad \textbf{(9.24)}$$

For convenience, we have set $t_0 = 0$, just as we did in Chapter 2 at this juncture. Next, we use equation 9.8, expressing the angular velocity as the derivative of the angle with respect to time and with the notation $\theta_0 = \theta(t = 0)$:

$$\begin{aligned}
&\frac{d\theta(t)}{dt} = \omega(t) = \omega_o + \alpha t \Rightarrow \\
&\theta(t) = \theta_0 + \int_0^t \omega(t')dt' = \theta_0 + \int_0^t (\omega_0 + \alpha t')dt' \Rightarrow \\
&= \theta_0 + \omega_0 \int_0^t dt' + \alpha \int_0^t t' dt' \Rightarrow \\
&\theta(t) = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2.
\end{aligned} \qquad \textbf{(9.25)}$$

Self-Test Opportunity 9.6

The derivation has been provided for two of these five kinematical equations for circular motion. Can you provide the derivation for the remaining equations? (*Hint:* The chain of reasoning proceeds along exactly the same lines as Derivation 2.1 in Chapter 2.)

Comparing equations 9.24 and 9.25 to equations (iii) and (i) for linear motion reveals that these two equations are the circular motion equivalents of the two kinematical equations for straight-line linear motion in one dimension. With the straightforward

substitutions $x \to \theta, v_x \to \omega,$ and $a_x \to \alpha,$ we can write five kinematical equations for circular motion under constant angular acceleration:

$$\begin{aligned}
&\text{(i)} && \theta = \theta_0 + \omega_0 t + \tfrac{1}{2}\alpha t^2 \\
&\text{(ii)} && \theta = \theta + \overline{\omega} t \\
&\text{(iii)} && \omega = \omega_0 + \alpha t \\
&\text{(iv)} && \overline{\omega} = \tfrac{1}{2}(\omega + \omega_0) \\
&\text{(v)} && \omega^2 = \omega_0^2 + 2\alpha(\theta - \theta_0).
\end{aligned} \tag{9.26}$$

EXAMPLE 9.5 Hammer Throw

One of the most interesting events in track-and-field competitions is the hammer throw. The task is to throw the "hammer," a 12-cm-diameter iron ball attached to a grip by a steel cable, a maximum distance. The hammer's total length is 121.5 cm, and its total mass is 7.26 kg. The athlete has to accomplish the throw from within a circle of radius 2.13 m (7 ft), and the best way to throw the hammer is for the athlete to spin, allowing the hammer to move in a circle around him, before releasing it. At the 1988 Olympic Games in Seoul, the Russian thrower Sergey Litvinov won the gold medal with an Olympic record distance of 84.80 m. He took seven turns before releasing the hammer, and the period to complete each turn was obtained from examining the video recording frame by frame: 1.52 s, 1.08 s, 0.72 s, 0.56 s, 0.44 s, 0.40 s, and 0.36 s.

PROBLEM 1

What was the average angular acceleration during the seven turns? Assume constant angular acceleration for the solution, and then check whether this assumption is justified.

SOLUTION 1

In order to find the average angular acceleration, we add all the time intervals for the seven turns, obtaining the total time:

$$t_{\text{all}} = 1.52\,\text{s} + 1.08\,\text{s} + 0.72\,\text{s} + 0.56\,\text{s} + 0.44\,\text{s} + 0.40\,\text{s} + ($$

During this time, Litvinov completed seven full turns, resulting in a total angle of

$$\theta_{\text{all}} = 7(2\pi\ \text{rad}) = 14\pi\ \text{rad}.$$

Because we are assuming constant acceleration, we can readily solve for the angular acceleration and insert the given numbers to obtain our answer:

$$\theta = \tfrac{1}{2}\alpha t^2 \Rightarrow \alpha = \frac{2\theta_{\text{all}}}{t^2} = 2\frac{14\pi \text{ rad}}{(5.08 \text{ s})^2} = 3.41 \text{ rad/s}^2.$$

DISCUSSION

Because we know how long it took to complete each turn, we can generate a plot of the angle of the hammer in the horizontal plane as a function of time. This plot is shown in Figure 9.20, with the red dots representing the data points. The blue line that is fit to the data points in Figure 9.20 assumes a constant angular acceleration of $\alpha = 3.41 \text{ rad/s}^2$. As you can see, the assumption of constant angular acceleration is almost, but not quite justified.

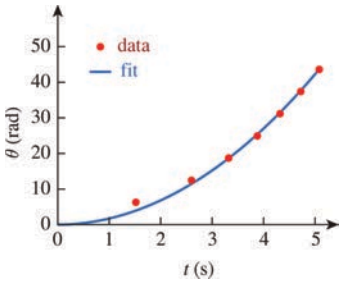


FIGURE 9.20
Angle as a function of time for Sergey Litvinov's 1988 gold-medal–winning hammer throw.

PROBLEM 2

Assuming that the radius of the circle on which the hammer moves is 1.67 m (the length of the hammer plus the arms of the athlete), what is the linear speed with which the hammer is released?

SOLUTION 2

With constant angular acceleration from rest for a period of 5.08 s, the final angular velocity is

$$\omega = \alpha t = \left(3.41 \text{ rad/s}^2\right)(5.08 \text{ s}) = 17.3 \text{ rad/s}.$$

Using the relationship between linear and angular velocity, we obtain the linear speed at release:

$$v = r\omega = (1.67\ \text{m})(17.3\ \text{rad/s}) = 28.9\ \text{m/s}.$$

PROBLEM 3

What is the centripetal force that the hammer thrower has to exert on the hammer right before he releases it?

SOLUTION 3

The centripetal acceleration right before release is given by

$$a_\text{c} = \omega^2 r = (17.3\ \text{rad/s})^2(1.67\ \text{m}) = 501.\ \text{m/s}^2.$$

With a mass of 7.26 kg for the hammer, the centripetal force required is

$$F_\text{c} = ma_\text{c} = (7.26\ \text{kg})\left(501.\ \text{m/s}^2\right) = 3640\ \text{N}.$$

This is an astonishingly large force, equivalent to the weight of an object of mass 371 kg! This is why world-class hammer throwers have to be very strong.

PROBLEM 4

After release, what is the direction in which the hammer moves?

SOLUTION 4

It is a common misconception that the hammer "spirals" in some sort of circular motion with an ever increasing radius after release. This idea is wrong because there is no horizontal component of force once the athlete releases the hammer. Newton's Second Law tells us that there will be no horizontal component of acceleration and hence no centripetal acceleration. Instead, the hammer moves in a direction that is tangential to the circle at the point of release. If you were to look straight down on the stadium from a blimp, you would see that the hammer moves

on a straight line, as shown in Figure 9.21. Viewed from the side, the shape of the hammer's trajectory is a parabola, as shown in Chapter 3.

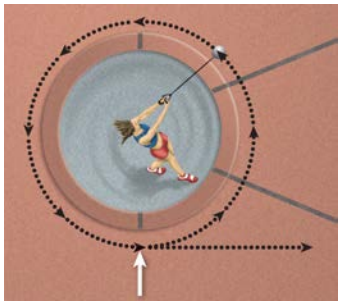

FIGURE 9.21
Overhead view of the trajectory of the hammer (black dots, with the arrows indicating the direction of the velocity vector) during the time the athlete holds on to it (circular path) and after release (straight line). The white arrow marks the point of release.

SOLVED PROBLEM 9.3 Flywheel

PROBLEM

The flywheel of a steam engine starts to rotate from rest with a constant angular acceleration of $\alpha = 1.43\,\text{rad/s}^2$. The flywheel undergoes this constant angular acceleration for $t = 25.9\,\text{s}$ and then continues to rotate at a constant angular velocity, ω. After the flywheel has been rotating for 59.5 s, what is the total angle through which it has rotated since it started?

SOLUTION

THINK

Here we are trying to determine the total angular displacement, θ. For the time interval when the flywheel is undergoing angular acceleration, we can use equation 9.26(i) with $\theta_0 = 0$ and $\omega_0 = 0$. When the flywheel is rotating at a constant angular velocity, we use equation 9.26(i) with $\theta_0 = 0$ and $\alpha = 0$. To get the total angular displacement, we add these two angular displacements.

SKETCH

A top view of the rotating flywheel is shown in Figure 9.22.

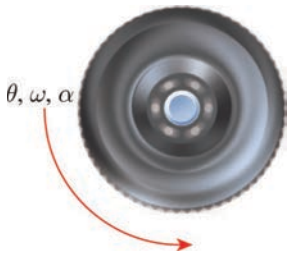

FIGURE 9.22 Top view of the rotating flywheel.

RESEARCH

Let's call the time during which the flywheel is undergoing angular acceleration t_a and the total time the flywheel is rotating t_b. Thus, the flywheel rotates at a constant angular velocity for a

time interval equal to $t_b - t_a$. The angular displacement, θ_a, that occurs while the flywheel is undergoing angular acceleration is given by

$$\theta_a = \tfrac{1}{2}\alpha t_a^2. \qquad \text{(i)}$$

The angular displacement, θ_b, that occurs while the flywheel is rotating at the constant angular velocity, ω, is given by

$$\theta_b = \omega(t_b - t_a). \qquad \text{(ii)}$$

The angular velocity, ω, reached by the flywheel after undergoing the angular acceleration α for a time t_a is given by

$$\omega = \alpha t_a. \qquad \text{(iii)}$$

The total angular displacement is given by

$$\theta_{total} = \theta_a + \theta_b. \qquad \text{(iv)}$$

SIMPLIFY

We can combine equations (ii) and (iii) to obtain the angular displacement while the flywheel is rotating at a constant angular velocity:

$$\theta_b = (\alpha t_a)(t_b - t_a) = \alpha t_a t_b - \alpha t_a^2. \qquad \text{(v)}$$

We can combine equations (v), (iv), and (i) to get the total angular displacement of the flywheel:

$$\theta_{total} = \theta_a + \theta_b = \tfrac{1}{2}\alpha t_a^2 + \left(\alpha t_a t_b - \alpha t_a^2\right) = \alpha t_a t_b - \tfrac{1}{2}\alpha t_a^2.$$

CALCULATE

Putting in the numerical values gives us

$$\theta_{\text{total}} = \alpha t_{\text{a}} t_{\text{b}} - \tfrac{1}{2}\alpha t_{\text{a}}^2 = \left(1.43\ \text{rad/s}^2\right)(25.9\ \text{s})(59.5\ \text{s}) - \tfrac{1}{2}($$
$$= 1724.07\ \text{rad}.$$

ROUND

Expressing our result to three significant figures, we have

$$\theta_{\text{total}} = 1720\ \text{rad}.$$

DOUBLE-CHECK

It is comforting that our answer has the right unit, the rad. Our formula, $\theta_{\text{total}} = \alpha t_{\text{a}} t_{\text{b}} - \tfrac{1}{2}\alpha t_{\text{a}}^2 = \alpha t_{\text{a}}\left(t_{\text{b}} - \tfrac{1}{2}t_{\text{a}}\right)$, gives a value that increases linearly with the value of the angular acceleration. It is also always larger than zero, as expected, because $t_{\text{b}} > t_{\text{a}}$.

To perform a further check, let's calculate the angular displacement in two steps. The first step is to calculate the angular displacement while the flywheel is accelerating

$$\theta_{\text{a}} = \tfrac{1}{2}\alpha t_{\text{a}}^2 = \tfrac{1}{2}\left(1.43\ \text{rad/s}^2\right)(25.9\ \text{s})^2 = 480\ \text{rad}.$$

The angular velocity of the flywheel after the angular acceleration ends is

$$\omega = \alpha t_{\text{a}} = \left(1.43\ \text{rad/s}^2\right)(25.9\ \text{s}) = 37.0\ \text{rad/s}.$$

Next, we calculate the angular displacement while the flywheel is rotating at constant velocity:

$$\theta_{\text{b}} = \omega(t_{\text{b}} - t_{\text{a}}) = (37.0\ \text{rad/s})(59.5\ \text{s} - 25.9\ \text{s}) = 1240\ \text{rad}$$

The total angular displacement is then

$$\theta_{\text{total}} = \theta_{\text{a}} + \theta_{\text{b}} = 480\,\text{rad} + 1240\,\text{rad} = 1720\ \text{rad},$$

which agrees with our answer.

9.7 More Examples for Circular Motion

Let's look at another example and solved problem that demonstrate how useful the concepts of circular motion we've just discussed are.

EXAMPLE 9.6 Formula 1 Racing

If you watch a Formula 1 race, you can see that the race cars approach curves from the outside, cut through to the inside, and then drift again to the outside, as shown by the red path in Figure 9.23a. The blue path is shorter. Why don't the drivers follow the shortest path?

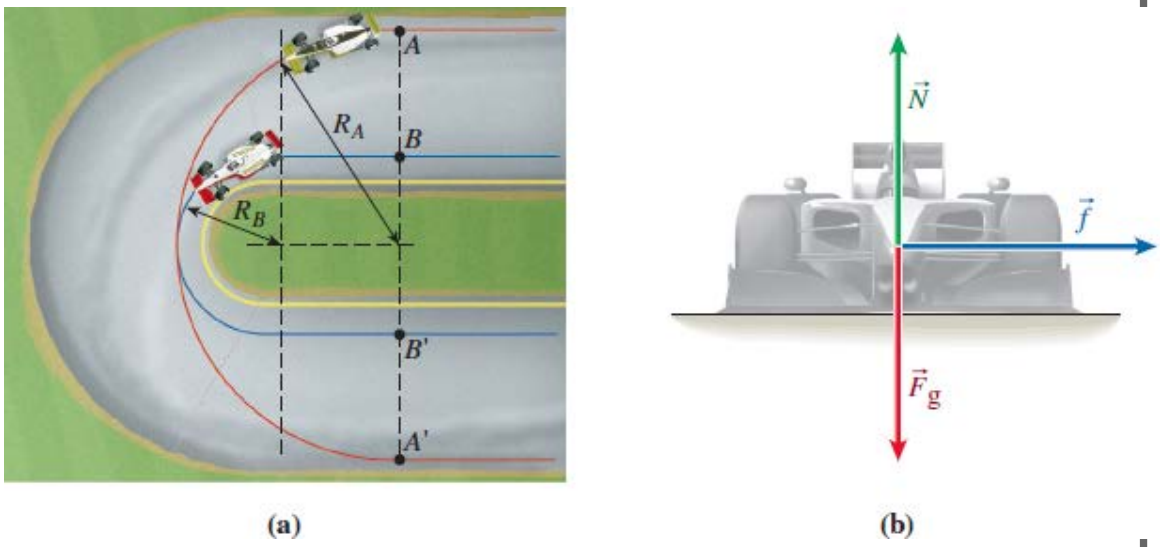

FIGURE 9.23 (a) Paths of race cars negotiating a turn on an oval track in two ways. (b) Free-body diagram for a race car in a curve.

PROBLEM

Suppose that cars move through the U-turn shown in Figure 9.23a at constant speed and that the coefficient of static friction between the tires and the road is $\mu_s = 1.2$. (As was mentioned in Chapter 4, modern race car tires can have coefficients of friction that exceed 1 when they are heated to race temperature and thus are very sticky.) If the radius of the inner curve shown in the figure is $R_B = 10.3$ m and radius of the outer is $R_A = 32.2$ m and the cars move at their maximum speed, how much time will it take to move from point A to A' and from point B to B'?

SOLUTION

We start by drawing a free-body diagram, as shown in Figure 9.23b. The diagram shows all forces that act on the car with the force arrows originating at the center of mass of the car. The force of gravity, acting downward with magnitude $F_{\text{g}} = mg$, is shown in red. This force is exactly balanced by the normal force, which the road exerts on the car, shown in green. As a car makes the turn, a net force is required to change the car's velocity vector and act as the centripetal force that pushes the car onto a circular path. This net force is generated by the friction force (shown in blue) between the car's tires and the road. This force arrow points horizontally and inward, toward the center of the curve. As usual, the magnitude of the friction force is the product of the normal force and the coefficient of friction: $f_{\text{max}} = \mu_{\text{s}} mg$. (*Note:* In this case, we use the equals sign, because the race car drivers push their cars and tires to the limit and thus reach the maximum possible static friction force.) The arrow for the friction force is longer than that for the normal force by a factor of 1.2, because $\mu_{\text{s}} = 1.2$.

First, we need to calculate the maximum velocity that a race car can have on each trajectory. For each radius of curvature, R, the resulting centripetal force, $F_{\text{c}} = mv^2/R$, must be provided by the friction force, $f_{\text{max}} = \mu_{\text{s}} mg$:

$$m\mu_{\text{s}} g = m\frac{v^2}{R} \Rightarrow v = \sqrt{\mu_{\text{s}} gR}.$$

Therefore, for the red and blue curves, we get

$$v_{\text{red}} = \sqrt{\mu_{\text{s}} gR_A} = \sqrt{(1.2)(9.81\ \text{m/s}^2)(32.2\ \text{m})} = 19.5\ \text{m/}$$
$$v_{\text{blue}} = \sqrt{\mu_{\text{s}} gR_B} = \sqrt{(1.2)(9.81\ \text{m/s}^2)(10.3\ \text{m})} = 11.0\ \text{m/}$$

These speeds are only about 43.6 mph and 24.6 mph, respectively! However, the curve shown is a very tight one, typically only encountered on a city course like the one in Monaco.

Even though a car can move much faster on the red curve, the blue curve is shorter than the red one. For the path length of the red curve, we simply have the distance along the semicircle, $\ell_{\text{red}} = \pi R_A = 101.\ \text{m}$. For the path length of the blue curve, we

have to add the two straight sections and the semicircular curve with the smaller radius:

$$\ell_{\text{bule}} = \pi R_B + 2(R_A - R_B) = 76.2 \text{ m}.$$

We then get for the time to go from A to A' on the red path:

$$t_{\text{red}} = \frac{\ell_{\text{red}}}{v_{\text{red}}} = \frac{101. \text{ m}}{19.5 \text{ m/s}} = 5.20 \text{ s}.$$

To travel along the blue curve from B to B' takes

$$t_{\text{blue}} = \frac{\ell_{\text{blue}}}{v_{\text{blue}}} = \frac{76.2 \text{ m}}{11.0 \text{ m/s}} = 6.92 \text{ s}.$$

With the assumption that the cars have to use a constant speed, it is clearly a big advantage to cut through the curve, as shown by the red path.

DISCUSSION

In a race situation, it is unreasonable to expect the car on the blue path to move along the straight-line segments with constant velocity. Instead, the driver will come to point B with the maximum speed that allows him to slow down to 11.0 m/s when entering the circular segment. If we worked this out in detail, we would find that the blue path is still slower, but not by much. In addition, the car following the blue path can reach point B with a slightly higher speed than that at which the red car can reach point A. In other words, we have a trade-off to consider before declaring a winner in this situation. In real races, cars slow down as they approach a curve and then accelerate as they come out of the curve. The most advantageous path for cutting through a curve is not the red semicircle, but a path that looks closer to elliptical, starting on the outside, cutting to the extreme inside in the middle of the turn, and then drifting to the outside again while accelerating out of the turn.

Formula 1 racing generally involves flat tracks and tight turns. Indy-style and NASCAR races take place on tracks with bigger

turning radii as well as banked curves. To study the forces involved in this type of racing situation, we must combine concepts of static equilibrium on an inclined plane with concepts of circular motion.

SOLVED PROBLEM 9.4 NASCAR Racing

As a NASCAR racer moves through a banked curve, the banking helps the driver achieve higher speeds. Let's see how. Figure 9.24 shows a race car on a banked curve.

FIGURE 9.24 Race car on a banked curve.

PROBLEM

If the coefficient of static friction between the track surface and the car's tires is $\mu_s = 0.620$ and the radius of the turn is $R = 110.\ \text{m}$, what is the maximum speed with which a driver can take a curve banked at $\theta = 21.1^\circ$? (This is a fairly typical banking angle for NASCAR tracks. Indianapolis has only 9° banking, but there are some tracks with banking angles over 30°, including Daytona (31°), Talladega (33°), and Bristol (36°).)

SOLUTION

THINK

The three forces acting on the race car are gravity, $\vec{F}_g$, the normal force, $\vec{N}$, and friction, $\vec{f}$. The curve is banked at an angle θ, which is also the angle between the normal to the track surface and the gravity force vector, as shown in Figure 9.25a. To draw the vector for the force of friction, we have assumed that the car has entered the curve at high speed, so the direction of the force of friction is down the incline. In contrast to the situation of static equilibrium, these three forces do not add up to zero, but instead add up to a net force, $\vec{F}_{net}$, as shown in Figure 9.25b. This net force has to provide the centripetal force, $\vec{F}_c$, which forces the car

to move in a circle. Thus, the net force has to act in the horizontal direction because this is the direction of the center of the circle in which the car is moving.

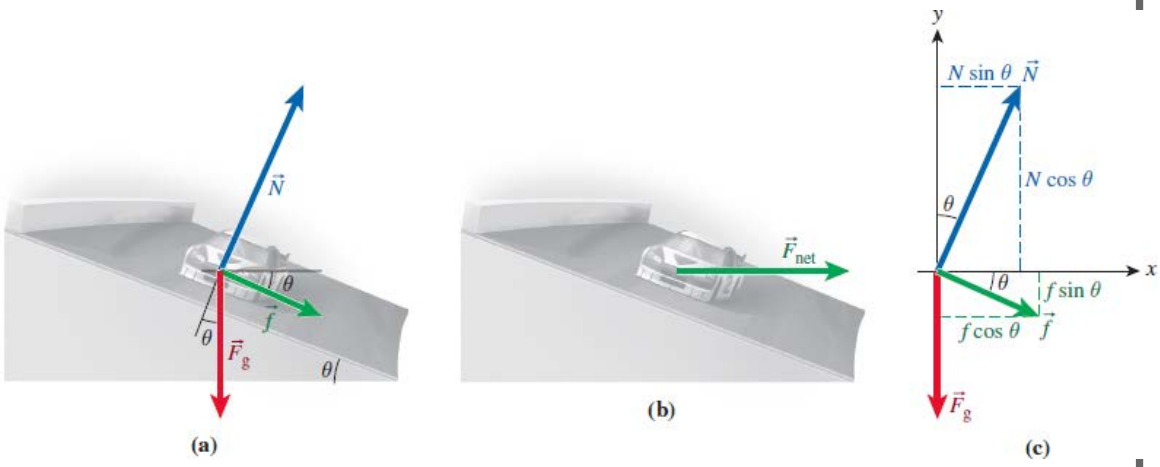

FIGURE 9.25 (a) Forces on a race car going around a banked curve on a racetrack. (b) The net force, the sum of the three forces in part (a). (c) A free-body diagram showing the *x*- and *y*-components of the forces acting on the car.

SKETCH

The free-body diagram for the race car on the banked curve, showing the *x*- and *y*-components of the forces, is presented in Figure 9.25c. The orientation for the coordinate system was selected to give a horizontal *x*-axis and a vertical *y*-axis.

RESEARCH

Like problems involving linear motion, we can solve problems involving circular motion by starting with the familiar Newton's Second Law: $\sum \vec{F} = m\vec{a}$. And just as in the linear case, we can generally work the problems in Cartesian components. From the free-body diagram in Figure 9.25c, we can see that the *x*-components of the forces acting on the race car are

$$N \sin\theta + f \cos\theta = F_{\text{net}}. \qquad \text{(i)}$$

Similarly, the forces acting in the *y*-direction are

$$N \cos\theta - F_g - f \sin\theta = 0. \qquad \text{(ii)}$$

As usual, the maximum friction force is given by the product of the coefficient of friction and the normal force: $f = \mu_s N$. The gravitational force is the product of mass and gravitational acceleration: $F_g = mg$.

The key to solving this problem is to realize that the net force has to be the force that causes the race car to move through the curve, that is, that provides the centripetal force. Therefore, using the expression for the centripetal force from equation 9.21, we have

$$F_{\text{net}} = F_c = m\frac{v^2}{R},$$

where R is the radius of the curve.

Page 283

SIMPLIFY

We insert the expressions for the maximum friction force, the gravitational force, and the net force into equations (i) and (ii) for the x- and y-components of the forces:

$$N \sin\theta + \mu_s N \cos\theta = m\frac{v^2}{R} \Rightarrow N(\sin\theta + \mu_s \cos\theta) = m\frac{v}{I}$$
$$N \cos\theta - mg - \mu_s N \sin\theta = 0 \Rightarrow N(\cos\theta - \mu_s \sin\theta) = m$$

This is a system of two equations for two unknown quantities: the magnitude of the normal force, N, and the speed of the car, v. It is easy to eliminate N by dividing the first equation above by the second:

$$\frac{\sin\theta + \mu_s \cos\theta}{\cos\theta - \mu_s \sin\theta} = \frac{v^2}{gR}.$$

We solve for v:

$$v = \sqrt{\frac{Rg(\sin\theta + \mu_s \cos\theta)}{\cos\theta - \mu_s \sin\theta}}. \qquad \text{(iii)}$$

Note that the mass of the car, m, canceled out. Thus, what matters in this situation is the coefficient of friction between the tires and the track surface, the radius of the turn, and the angle of banking.

CALCULATE

Putting in the numbers, we obtain

$$v = \sqrt{\frac{(110.\ \text{m})(9.81\ \text{m/s}^2)\left[\sin 21.1^\circ + 0.620(\cos 21.1^\circ)\right]}{\cos 21.1^\circ - 0.620(\sin 21.1^\circ)}}.$$

ROUND

Expressing our result to three significant figures gives us

$$v = 37.8\ \text{m/s}.$$

DOUBLE-CHECK

To double-check our result, let's compare the speed for a banked curve to the maximum speed a race car can achieve on a curve with the same radius but without banking. Without banking, the only force keeping the race car on the circular path is the force of friction. Then our result reduces to the equation $v = \sqrt{\mu_s g R}$ that we found in Example 9.6, and we can insert the numerical values given here to obtain the maximum speed around a flat curve of the same radius:

$$v = \sqrt{\mu_s g R} = \sqrt{(0.620)(9.81\ \text{m/s}^2)(110.\ \text{m})} = 25.9\ \text{m/s}.$$

Our result for the maximum speed around a banked curve, 37.8 m/s (84.6 mph), is considerably larger than this result for a

flat curve, 25.9 m/s (57.9 mph), which seems reasonable.

Note that the vector for the force of friction in Figure 9.25 points along the surface of the track and toward the inside of the curve, just as the friction force vector for the nonbanked curve does in Figure 9.23b. However, you can see that as the banking angle increases, it reaches a value for which the denominator of the velocity formula, equation (iii), approaches zero. This occurs when $\cot\theta = \mu_s$. For the given value, $\mu_s = 0.620$, this angle is 58.2°. For larger angles, the driver needs to maintain a minimum speed driving through the curve to prevent the car from sliding to the bottom of the incline.

WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- The conversion between Cartesian coordinates, x and y, and polar coordinates, r and θ, is given by

$$r = \sqrt{x^2 + y^2}$$
$$\theta = \tan^{-1}(y/x).$$

- The conversion between polar coordinates and Cartesian coordinates is given by

$$x = r \cos \theta$$
$$y = r \sin \theta.$$

- For circular motion, the linear displacement, s, is related to the angular displacement, θ, by $s = r\theta$, where r is the radius of the circular path and θ is measured in radians.
- The magnitude of the instantaneous angular velocity, ω, is given by $\omega = \dfrac{d\theta}{dt}$.
- The magnitude of the angular velocity is related to the magnitude of the linear velocity, v, by $v = r\omega$.
- The magnitude of the instantaneous angular acceleration, α, is given by

$$\alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}.$$

- The magnitude of the angular acceleration is related to the magnitude of the tangential acceleration, a_t, by $a_t = r\alpha$.

- The magnitude of the centripetal acceleration, a_{c}, required to keep an object moving in a circle with constant angular velocity is given by $a_{\mathrm{c}} = \omega^2 r = \dfrac{v^2}{r}$.
- The magnitude of the total acceleration of an object in circular motion is $a = \sqrt{a_{\mathrm{t}}^2 + a_{\mathrm{c}}^2} = r\sqrt{\alpha^2 + \omega^4}$.
- The kinematical equations for circular motion are

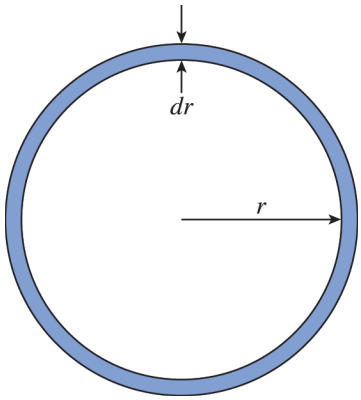
$$\begin{aligned}
\theta &= \theta_0 + \omega_0 t + \tfrac{1}{2}\alpha t^2 \\
\theta &= \theta_0 + \overline{\omega} t \\
\omega &= \omega_0 + \alpha t \\
\overline{\omega} &= \tfrac{1}{2}(\omega + \omega_0) \\
\omega^2 &= \omega_0^2 + 2\alpha(\theta - \theta_0).
\end{aligned}$$

Answers to Self-Test Opportunities

9.1 Differential arc length is $R dv$ for a circle with radius R; integral arc length around the circle is the circumference C:

$$C = \int_0^{2\pi} r d\,\theta = r \int_0^{2\pi} d\,\theta = r[\theta]_0^{2\pi} = 2\pi r.$$

9.2 The differential area is shown in the sketch. The differential area is $dA = 2\pi dr$. Area of a circle is

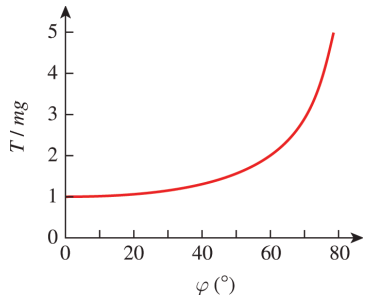


$$\int_0^R 2\pi r\, dr = 2\pi \int_0^R r\, dr$$

$$= 2\pi \left[\frac{r^2}{2}\right]^R = \pi R^2.$$

9.3 $\omega^2 r = (2\pi/\text{yr})^2 (1\text{ au}) = 5.9 \cdot 10^{-3} \text{m/s}^2 \approx g/1700.$

9.4



9.5 If the radius is doubled, the speed at the top of the loop has to increase by a factor of $\sqrt{2}$. Thus, the required speed is $(7.00\ \text{m/s})\left(\sqrt{2}\right) = 9.90\ \text{m/s}$.

9.6 (iv)
$$\overline{\omega} = \frac{1}{t}\int_0^t \omega(t')\,dt' = \frac{1}{t}\int_0^t (\omega_0 + \alpha t')\,dt'$$
$$= \frac{\omega_0}{t}\int_0^t dt' + \frac{\alpha}{t}\int_0^t t'\,dt' = \omega_0 + \frac{1}{2}\alpha t$$
$$= \frac{1}{2}\omega_0 + \frac{1}{2}(\omega_0 + \alpha t)$$
$$= \frac{1}{2}(\omega_0 + \omega)$$

(ii) $$\overline{\omega} = \omega_0 + \frac{1}{2}\alpha t$$
$$\Rightarrow \overline{\omega} t = \omega_0 t + \frac{1}{2}\alpha t^2$$
$$\theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2 = \theta_0 + \overline{\omega} t$$

(v) $$\theta = \theta_0 + \omega_0 t + \frac{1}{2}\alpha t^2$$
$$= \theta_0 + \omega_0\left(\frac{\omega - \omega_0}{\alpha}\right) + \frac{1}{2}\alpha\left(\frac{\omega - \omega_0}{\alpha}\right)^2$$
$$= \theta_0 + \frac{\omega\omega_0 - \omega_0^2}{\alpha} + \frac{1}{2}\frac{\omega^2 + \omega_0^2 - 2\omega\omega_0}{\alpha}$$

Now we subtract θ_0 from both sides of the equation and then multiply by α:

$$\alpha(\theta - \theta_0) = \omega\omega_0 - \omega_0^2 + \frac{1}{2}\left(\omega^2 + \omega_0^2 - 2\omega\omega_0\right)$$

$$\Rightarrow \alpha(\theta - \theta_0) = \frac{1}{2}\omega^2 - \frac{1}{2}\omega_0^2$$

$$\Rightarrow \omega^2 = \omega_0^2 + 2\alpha(\theta - \theta_0)$$

PROBLEM-SOLVING GUIDELINES: CIRCULAR MOTION

1. Motion in a circle always involves centripetal force and centripetal acceleration. However, remember that centripetal force is not a new kind of force but is simply the net force causing the motion; it consists of the sum of whatever forces are acting on the moving object. This net force equals the mass times the centripetal acceleration; do not make the common mistake of counting mass times acceleration as a force to be added to the net force on one side of the equation of motion.

2. Be sure you note whether the situation involves angles in degrees or in radians. The radian is not a unit that necessarily has to be carried through a calculation, but check that your result makes sense in terms of the angular units.

3. The equations of motion with constant angular acceleration have the same form as the equations of motion with constant linear acceleration. However, neither set of equations applies if the acceleration is not constant.

Multiple-Choice Questions

9.1 An object is moving in a circular path. If the centripetal force is suddenly removed, how will the object move?

a) It will move radially outward.

b) It will move radially inward.

c) It will move vertically downward.

d) It will move in the direction in which its velocity vector points at the instant the centripetal force vanishes.

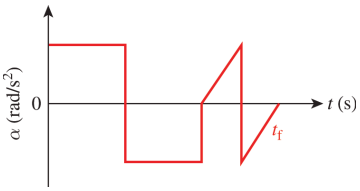
9.2 The angular acceleration for an object undergoing circular motion is plotted versus time in the figure. If the object started from rest at $t = 0$, the net angular displacement of the object at $t = t_f$

a) is in the clockwise direction.

b) is in the counterclockwise direction.

c) is zero.

d) cannot be determined.



9.3 The latitude of Lubbock, Texas (known as the Hub City of the South Plains), is 33° N. What is its rotational speed, assuming the radius of the Earth at the Equator to be 6380 km?

a) 464 m/s

b) 389 m/s

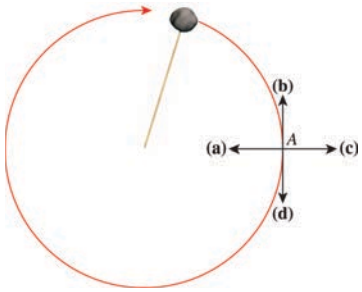
c) 253 m/s

d) 0.464 m/s

e) 0.389 m/s

9.4 A rock attached to a string moves clockwise in uniform circular motion. In which direction from point A is the rock thrown off when

the string is cut?



9.5 A Ferris wheel rotates slowly about a horizontal axis. Passengers sit on seats that remain horizontal on the Ferris wheel as it rotates. Which type of force provides the centripetal acceleration on the passengers when they are at the top of the Ferris wheel?

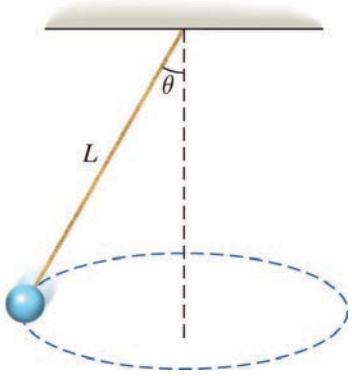
a) centrifugal

b) normal

c) gravity

d) tension

9.6 In a conical pendulum, a bob moves in a horizontal circle, as shown in the figure. The period of the pendulum (the time it takes for the bob to perform a complete revolution) is



a) $T = 2\pi\sqrt{L\cos\theta/g}$.

b) $T = 2\pi\sqrt{g\cos\theta/L}$.

c) $T = 2\pi\sqrt{Lg\sin\theta}$.

d) $T = 2\pi\sqrt{L\sin\theta/g}$.

e) $T = 2\pi\sqrt{L/g}$.

9.7 A ball attached to the end of a string is swung around in a circular path of radius *r*. If the radius is doubled and the linear speed is kept constant, the centripetal acceleration

a) remains the same.

b) increases by a factor of 2.

c) decreases by a factor of 2.

d) increases by a factor of 4.

e) decreases by a factor of 4.

9.8 The angular speed of the hour hand of a clock (in radians per second) is

a) $\frac{\pi}{21{,}600}$.

b) $\frac{\pi}{7200}$.

c) $\frac{\pi}{3600}$.

d) $\frac{\pi}{1800}$.

e) $\frac{\pi}{60}$.

9.9 You put three identical coins on a turntable at different distances from the center and then turn the motor on. As the turntable speeds up, the outermost coin slides off first, followed by the one at the middle distance, and, finally, when the turntable is going the fastest, the innermost one. Why is this?

a) For greater distances from the center, the centripetal acceleration is higher, and so the force of friction becomes unable to hold the coin in place.

b) The weight of the coin causes the turntable to flex downward, so the coin nearest the edge falls off first.

c) Because of the way the turntable is made, the coefficient of static friction decreases with distance from the center.

d) For smaller distances from the center, the centripetal acceleration is higher.

9.10 A point on a disk is a distance $R/4$ from the axis of rotation. How far from the axis of rotation is a second point that has, at any instant, a linear velocity twice that of the first point?

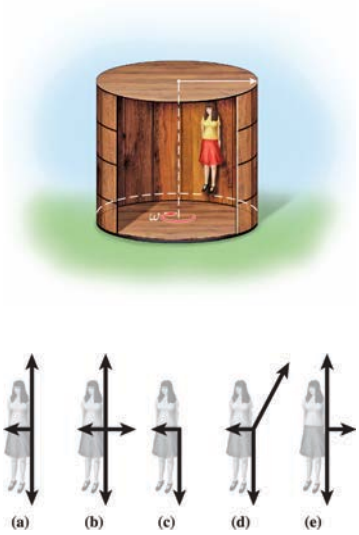
a) $R/16$

b) $R/8$

c) $R/2$

d) R

9.11 The figure shows a rider stuck to the wall without touching the floor in the Barrel of Fun at a carnival. Which diagram correctly shows the forces acting on the rider?



9.12 A string is tied to a rock, and the rock is twirled around in a circle at a constant speed. If gravity is ignored and the period of the circular motion is doubled, the tension in the string is

a) reduced to $\frac{1}{4}$ of its original value.

b) reduced to $\frac{1}{2}$ of its original value.

c) unchanged.

d) increased to two times its original value.

e) increased to four times its original value.

9.13 A bicycle's wheels have a radius of 33.0 cm. The bicycle is traveling at a speed of 6.5 m/s. What is the angular speed of the front tire?

a) 0.197 rad/s

b) 1.24 rad/s

c) 5.08 rad/s

d) 19.7 rad/s

e) 215 rad/s

9.14 The period of rotation of the Earth on its axis is 24 h. At this angular velocity, the centripetal acceleration at the surface of the Earth is small compared with the acceleration due to gravity. What would Earth's period of rotation have to be for the magnitude of the centripetal acceleration at its surface at the Equator to be equal to the magnitude of the acceleration due to gravity? (With this period of rotation, you could levitate just above the Earth's surface!)

a) 0.043 h

b) 0.340 h

c) 0.841 h

d) 1.41 h

e) 3.89 h

f) 12.0 h

9.15 In Solved Problem 9.1, with what speed does the roller-coaster car have to enter the bottom of the loop in order to produce the feeling of weightlessness at the top?

a) 7.00 m/s

b) 12.1 m/s

c) 13.5 m/s

d) 15.7 m/s

e) 21.4 m/s

9.16 Figure 9.16a shows the free-body diagram for the forces acting on a passenger in a roller-coaster car at the top of the loop, where the

normal force exerted by the track has a magnitude smaller than that of the gravitational force. If the speed of the car is 7.00 m/s, what does the radius of the loop have to be for that free-body diagram to be correct?

a) less than 5 m

b) 5 m

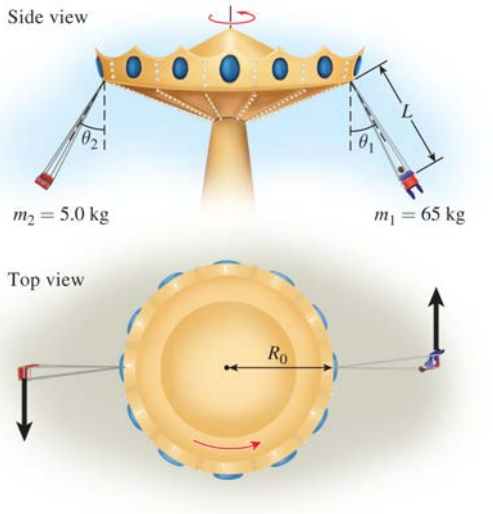
c) more than 5 m

CONCEPTUAL QUESTIONS

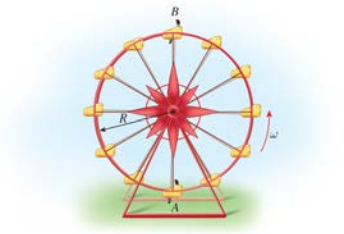
9.17 A ceiling fan is rotating in clockwise direction (as viewed from below), but it is slowing down. What are the directions of ω and α?

9.18 A hook above a stage is rated to support 150. lb. A 3.00-lb rope is attached to the hook, and a 147-lb actor is going to attempt to swing across the stage on the rope. Will the hook hold the actor up during the swing?

9.19 A popular carnival ride consists of seats attached to a central disk through cables, as shown in the figure. The passengers travel in uniform circular motion. The mass of one of the passengers (including the chair he is sitting on) is 65 kg; the mass of an empty chair on the opposite side of the central disk is 5.0 kg. If θ_1 and θ_2 are the angles that the cables attached to the two chairs make with respect to vertical, how do these two angles compare qualitatively? Is θ_2 larger than, smaller than, or equal to θ_1?



9.20 A person rides on a Ferris wheel of radius R, which is rotating at a constant angular velocity ω. Compare the normal force of the seat pushing up on the person at point A to that at point B in the figure. Which force is greater, or are they the same?



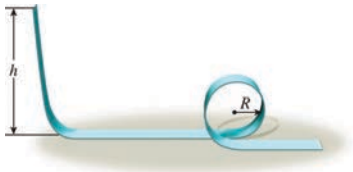
9.21 Bicycle tires range in size from about 25. cm in diameter to about 70. cm in diameter. Why is it impractical to make tires much smaller than 25. cm in diameter? (You will learn why bicycle tires can't be too large in Chapter 10.)

9.22 A disk starts from rest and speeds up to the operating angular frequency of the disk player, 33.33 rpm. Compare the angular velocity and acceleration of a point on the edge of the disk to those of a point halfway between the center and the edge of the disk. Do the same for the linear velocity and acceleration.

9.23 A car is traveling around an unbanked curve at a maximum speed. Which force(s) is(are) responsible for keeping it on the road?

9.24 Two masses hang from two strings of equal length that are attached to the ceiling of a car. One mass is over the driver's seat; the other is over the passenger's seat. As the car makes a sharp turn, both masses swing away from the center of the turn. In their resulting positions, will they be farther apart, closer together, or the same distance apart as they were when the car wasn't turning?

9.25 A point mass m starts sliding from a height h along the frictionless surface shown in the figure. What is the minimum value of h in order for the mass to complete the loop of radius R?

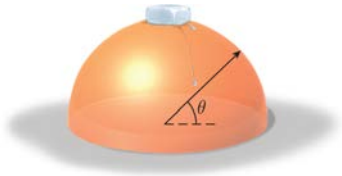


9.26 In a conical pendulum, the bob attached to the string (which can be considered massless) moves in a horizontal circle at constant

speed. The string sweeps out a cone as the bob rotates. What forces are acting on the bob?

9.27 Is it possible to swing a mass attached to a string in a perfectly horizontal circle (with the mass and the string parallel to the ground)?

9.28 A small ice block of mass m starts from rest from the top of an inverted bowl in the shape of a hemisphere, as shown in the figure. The hemisphere is fixed to the ground, and the block slides without friction along the surface of the hemisphere. Find the normal force exerted by the block on the sphere when the line between the block and the center of the sphere makes an angle θ with the horizontal. Discuss the result.



9.29 Suppose you are riding on a roller coaster, which moves through a vertical circular loop. Show that your apparent weight at the bottom of the loop is six times your weight when you experience weightlessness at the top, independent of the size of the loop. Assume that friction is negligible.

9.30 The following event actually occurred on the Sunshine Skyway Bridge near St. Petersburg, Florida, in 1997. Five daredevils tied a 55-m-long cable to the center of the bridge. They hoped to swing back and forth under the bridge at the end of this cable. The five people (total weight $= W$) attached themselves to the end of the cable, at the same level and 55 m away from where it was attached to the bridge and dropped straight down from the bridge, following the dashed circular path indicated in the figure. Unfortunately, the daredevils were not well versed in the laws of physics, and the cable broke (at the point it was linked to their seats) at the bottom of their swing. Determine how strong the cable (and all the links where the seats and the bridge are attached to it) would have had to be in order to support the five people at the bottom of the swing. Express your result in terms of their total weight, W.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 9.2

9.31 What is the angle in radians that the Earth sweeps out in its orbit during winter?

9.32 Assuming that the Earth is spherical and recalling that latitudes range from 0° at the Equator to 90° N at the North Pole, how far apart, measured on the Earth's surface, are Dubuque, Iowa 42.50° N latitude), and Guatemala City (14.62° N latitude)? The two cities lie on approximately the same longitude. Do *not* neglect the curvature of the Earth in determining this distance.

•**9.33** Refer to the information given in Problem 9.32. If one could burrow through the Earth and dig a straight-line tunnel from Dubuque to Guatemala City, how long would the tunnel be? From the point of view of the digger, at what angle below the horizontal would the tunnel be directed?

Section 9.3

9.34 A baseball is thrown at approximately 88.0 mph and with a spin rate of 110. rpm. If the distance between the pitcher's point of release and the catcher's glove is 60.5 ft, how many full turns does the ball make between release and catch? Neglect any effect of gravity or air resistance on the ball's flight.

9.35 A vinyl record plays at 33.3 rpm. Assume it takes 5.00 s for it to reach this full speed, starting from rest.

a) What is its angular acceleration during the 5.00 s?

b) How many revolutions does the record make before reaching its final angular speed?

9.36 At a county fair, a boy takes his teddy bear on the giant Ferris wheel. Unfortunately, at the top of the ride, he accidentally drops his stuffed buddy. The wheel has a diameter of 12.0 m, the bottom of the wheel is 2.00 m above the ground and its rim is moving at a speed of 1.00 m/s. How far from the base of the Ferris wheel will the teddy bear land?

•**9.37** Having developed a taste for experimentation, the boy in Problem 9.36 invites two friends to bring their teddy bears on the same Ferris wheel. The boys are seated in positions 45.0° from each other. When the wheel brings the second boy to the maximum height, they all drop their stuffed animals. How far apart will the three teddy bears land?

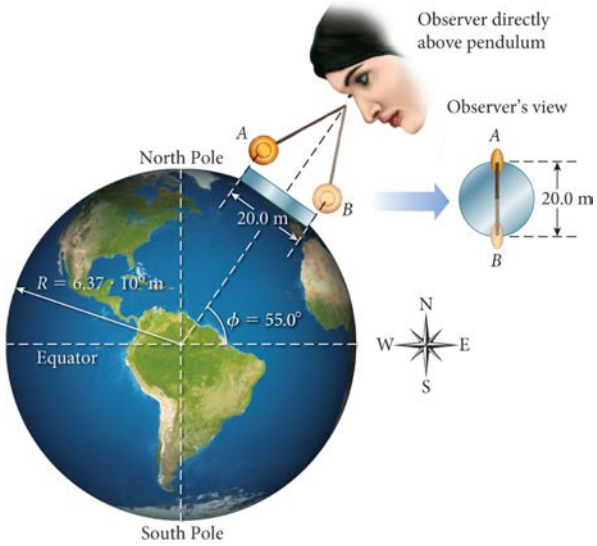
•**9.38** Mars orbits the Sun at a mean distance of 228 million km, in a period of 687 days. The Earth orbits at a mean distance of 149.6 million km, in a period of 365.26 days.

a) Suppose Earth and Mars are positioned such that Earth lies on a straight line between Mars and the Sun. Exactly 365.26 days later, when the Earth has completed one orbit, what is the angle between the Earth-Sun line and the Mars-Sun line?

b) The initial situation in part (a) is a closest approach of Mars to Earth. What is the time, in days, between two closest approaches? Assume constant speed and circular orbits for both Mars and Earth.

c) Another way of expressing the answer to part (b) is in terms of the angle between the lines drawn through the Sun, Earth, and Mars in the two closest approach situations. What is that angle?

••9.39 Consider a large simple pendulum that is located at a latitude of 55.0° N and is swinging in a north-south direction with points *A* and *B* being the northernmost and the southernmost points of the swing, respectively. A stationary (with respect to the fixed stars) observer is looking directly down on the pendulum at the moment shown in the figure. The Earth is rotating once every 23 h and 56 min.



a) What are the directions (in terms of N, E, W, and S) and the magnitudes of the velocities of the surface of the Earth at points *A* and *B* as seen by the observer? *Note*: You will need to calculate answers to at least seven significant figures to see a difference.

b) What is the angular speed with which the 20.0-m diameter circle under the pendulum appears to rotate?

c) What is the period of this rotation?

d) What would happen to a pendulum swinging at the Equator?

Section 9.4

9.40 What is the centripetal acceleration of the Moon? The period of the Moon's orbit about the Earth is 27.3 days, measured with respect to the fixed stars. The radius of the Moon's orbit is $R_{\mathrm{M}} = 3.85 \cdot 10^8$ m.

9.41 You are holding the axle of a bicycle wheel with radius 35.0 cm and mass 1.00 kg. You get the wheel spinning at a rate of 75.0 rpm and then stop it by pressing the tire against the pavement. You notice that it takes 1.20 s for the wheel to come to a complete stop. What is the angular acceleration of the wheel?

9.42 Life scientists use ultracentrifuges to separate biological components or to remove molecules from suspension. Samples in a symmetric array of containers are spun rapidly about a central axis. The centrifugal acceleration they experience in their moving reference frame acts as "artificial gravity" to effect a rapid separation. If the sample containers are 10.0 cm from the rotation axis, what rotation frequency is required to produce an acceleration of $1.00 \cdot 10^5 g$?

9.43 A centrifuge in a medical laboratory rotates at an angular speed of 3600. rpm (revolutions per minute). When switched off, it rotates 60.0 times before coming to rest. Find the constant angular acceleration of the centrifuge.

9.44 A discus thrower (with arm length of 1.20 m) starts from rest and begins to rotate counterclockwise with an angular acceleration of $2.50\ \mathrm{rad/s^2}$.

a) How long does it take the discus thrower's speed to get to $4.70\ \mathrm{rad/s}$?

b) How many revolutions does the thrower make to reach the speed of $4.70\ \mathrm{rad/s}$?

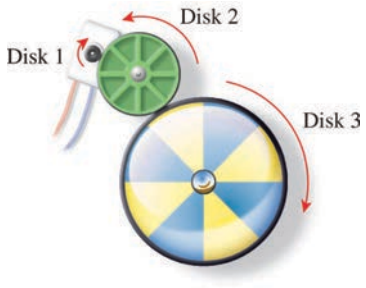
c) What is the linear speed of the discus at $4.70\ \mathrm{rad/s}$?

d) What is the linear acceleration of the discus thrower at this point?

e) What is the magnitude of the centripetal acceleration of the discus thrown?

f) What is the magnitude of the discus's total acceleration?

•**9.45** In a department store toy display, a small disk (disk 1) of radius 0.100 m is driven by a motor and turns a larger disk (disk 2) of radius 0.500 m. Disk 2, in turn, drives disk 3, whose radius is 1.00 m. The three disks are in contact, and there is no slipping. Disk 3 is observed to sweep through one complete revolution every 30.0 s.



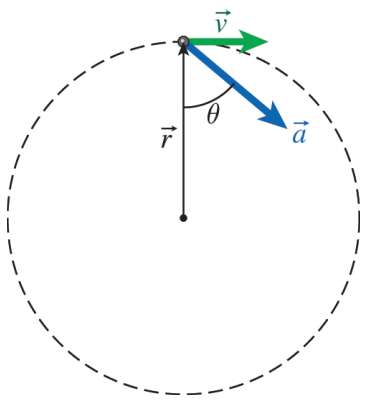
a) What is the angular speed of disk 3?

b) What is the ratio of the tangential velocities of the rims of the three disks?

c) What are the angular speeds of disks 1 and 2?

d) If the motor malfunctions, resulting in an angular acceleration of $0.100\ \text{rad/s}^2$ for disk 1, what are disks 2 and 3's angular accelerations?

•**9.46** A particle is moving clockwise in a circle of radius 1.00 m. At a certain instant, the magnitude of its acceleration is $a = \left|\vec{a}\right| = 25.0\ \text{m/s}^2$, and the acceleration vector has an angle of $\theta = 50.0^\circ$ with the position vector, as shown in the figure. At this instant, find the speed, $v = \left|\vec{v}\right|$, of this particle.



•9.47 In a tape recorder, the magnetic tape moves at a constant linear speed of 5.60 cm/s. To maintain this constant linear speed, the angular speed of the driving spool (the take-up spool) has to change accordingly.

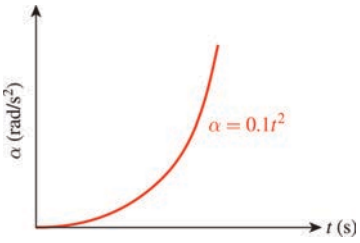
a) What is the angular speed of the take-up spool when it is empty, with radius $r_1 = 0.800$ cm?

b) What is the angular speed when the spool is full, with radius $r_2 = 2.20$ cm?

c) If the total length of the tape is 100.80 m, what is the average angular acceleration of the take-up spool while the tape is being played?

••9.48 A ring is fitted loosely (with no friction) around a long, smooth rod of length $L = 0.500$ m. The rod is fixed at one end, and the other end is spun in a horizontal circle at a constant angular velocity of $\omega = 4.00$ rad/s. The ring has zero radial velocity at its initial position, a distance of $r_0 = 0.300$ m from the fixed end. Determine the radial velocity of the ring as it reaches the moving end of the rod.

••9.49 A flywheel with a diameter of 1.00 m is initially at rest. Its angular acceleration is plotted versus time in the figure.



a) What is the angular separation between the initial position of a fixed point on the rim of the flywheel and the point's position 8.00 s after the wheel starts rotating?

b) The point starts its motion at $\theta = 0$. Calculate and sketch the linear position, velocity vector, and acceleration vector 8 s after the wheel starts rotating.

Section 9.5

9.50 Calculate the centripetal force exerted on a vehicle of mass $m = 1500.$ kg that is moving at a speed of 15.0 m/s around a curve of radius $R = 400.$ m. Which force plays the role of the centripetal force in this case?

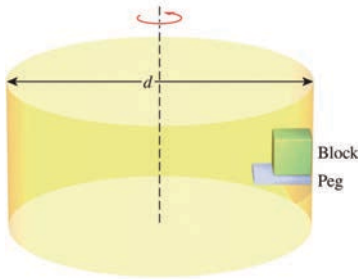
9.51 What is the apparent weight of a rider on the roller coaster of Solved Problem 9.1 at the *bottom* of the loop?

9.52 Two skaters, A and B, of equal mass are moving in clockwise uniform circular motion on the ice. Their motions have equal periods, but the radius of skater A's circle is half that of skater B's circle.

a) What is the ratio of the speeds of the skaters?

b) What is the ratio of the magnitudes of the forces acting on each skater?

•**9.53** A small block of mass m is in contact with the inner wall of a large hollow cylinder. Assume the coefficient of static friction between the object and the wall of the cylinder is μ_s. Initially, the cylinder is at rest, and the block is held in place by a peg supporting its weight. The cylinder starts rotating about its center axis, as shown in the figure, with an angular acceleration of α. Determine the minimum time interval after the cylinder begins to rotate before the peg can be removed without the block sliding against the wall.



•**9.54** A race car is making a U-turn at constant speed. The coefficient of friction between the tires and the track is $\mu_s = 1.20$. If the radius of the curve is 10.0 m, what is the maximum speed at

which the car can turn without sliding? Assume that the car is undergoing uniform circular motion.

•9.55 A car speeds over the top of a hill. If the radius of curvature of the hill at the top is 9.00 m, how fast can the car be traveling and maintain constant contact with the ground?

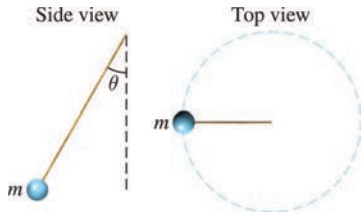
•9.56 A ball of mass $m = 0.200$ kg is attached to a (massless) string of length $L = 1.00$ m and is undergoing circular motion in the horizontal plane, as shown in the figure.

a) Draw a free-body diagram for the ball.

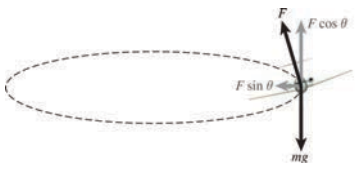
b) Which force plays the role of the centripetal force?

c) What should the speed of the mass be for θ to be 45.0°?

d) What is the tension in the string?



•9.57 You are flying to Chicago for a weekend away from the books. In your last physics class, you learned that the airflow over the wings of the plane creates a *lift force,* which acts perpendicular to the wings. When the plane is flying level, the upward lift force exactly balances the downward *weight force*. Since O'Hare is one of the busiest airports in the world, you are not surprised when the captain announces that the flight is in a holding pattern due to the heavy traffic. He informs the passengers that the plane will be flying in a circle of radius 7.00 mi at a speed of 360. mph and an altitude of $2.00 \cdot 10^4$ ft. From the safety information card, you know that the total length of the wingspan of the plane is 275 ft. From this information, estimate the banking angle of the plane relative to the horizontal.



•• **9.58** A 20.0-g metal cylinder is placed on a turntable, with its center 80.0 cm from the turntable's center. The coefficient of static friction between the cylinder and the turntable's surface is $\mu_s = 0.800$. A thin, massless string of length 80.0 cm connects the center of the turntable to the cylinder, and *initially*, the string has zero tension in it. Starting from rest, the turntable very slowly attains higher and higher angular velocities, but the turntable and the cylinder can be considered to have uniform circular motion at any instant. Calculate the tension in the string when the angular velocity of the turntable is 60.0 rpm (rotations per minute).

••**9.59** A speedway turn, with radius of curvature R, is banked at an angle θ above the horizontal.

a) What is the optimal speed at which to take the turn if the track's surface is iced over (that is, if there is very little friction between the tires and the track)?

b) If the track surface is ice-free and there is a coefficient of friction μ_s between the tires and the track, what are the maximum and minimum speeds at which this turn can be taken?

c) Evaluate the results of parts (a) and (b) for $R = 400.\ \text{m}, \theta = 45.0^\circ$, and $\mu_s = 0.700$.

Additional Exercises

9.60 A particular Ferris wheel takes riders in a vertical circle of radius 9.00 m once every 12.0 s.

a) Calculate the speed of the riders, assuming it to be constant.

b) Draw a free-body diagram for a rider at a time when she is at the bottom of the circle. Calculate the normal force exerted by the seat on the rider at that point in the ride.

c) Perform the same analysis as in part (b) for a point at the top of the ride.

9.61 A boy is on a Ferris wheel, which takes him in a vertical circle of radius 9.00 m once every 12.0 s.

a) What is the angular speed of the Ferris wheel?

b) Suppose the wheel comes to a stop at a uniform rate during one quarter of a revolution. What is the angular acceleration of the wheel during this time?

c) Calculate the tangential acceleration of the boy during the time interval described in part (b).

9.62 Consider a 53.0-cm-long lawn mower blade rotating about its center at 3400. rpm.

a) Calculate the linear speed of the tip of the blade.

b) If safety regulations require that the blade be stoppable within 3.00 s, what minimum angular acceleration will accomplish this? Assume that the angular acceleration is constant.

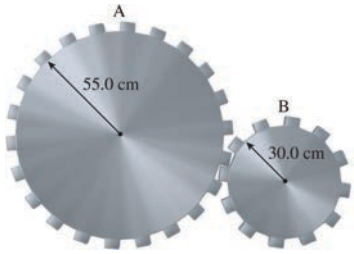
9.63 A car accelerates uniformly from rest and reaches a speed of 22.0 m/s in 9.00 s. The diameter of a tire on this car is 58.0 cm.

a) Find the number of revolutions the tire makes during the car's motion, assuming that no slipping occurs.

b) What is the final angular speed of a tire in revolutions per second?

9.64 Gear A, with a mass of 1.00 kg and a radius of 55.0 cm, is in contact with gear B, with a mass of 0.500 kg and a radius of 30.0 cm. The gears do not slip with respect to each other as they rotate. Gear A

rotates at 120. rpm and slows to 60.0 rpm in 3.00 s. How many rotations does gear B undergo during this time interval?



9.65 A top spins for 10.0 min, beginning with an angular speed of 10.0 rev/s. Determine its angular acceleration, assuming it is constant, and its total angular displacement.

9.66 A penny is sitting on the edge of an old phonograph disk that is spinning at 33.0 rpm and has a diameter of 12.0 inches. What is the minimum coefficient of static friction between the penny and the surface of the disk to ensure that the penny doesn't fly off?

9.67 A vinyl record that is initially turning at $33\frac{1}{3}$ rpm slows uniformly to a stop in a time of 15.0 s. How many rotations are made by the record while stopping?

9.68 Determine the linear and angular speeds and accelerations of a speck of dirt located 2.00 cm from the center of a disk rotating at 250. rpm.

9.69 What is the acceleration of the Earth in its orbit? (Assume the orbit is circular.)

9.70 A day on Mars is 24.6 Earth hours long. A year on Mars is 687 Earth days long. How do the angular velocities of Mars's rotation and orbit compare to the angular velocities of Earth's rotation and orbit?

9.71 A monster truck has tires with a diameter of 1.10 m and is traveling at 35.8 m/s. After the brakes are applied, the truck slows uniformly and is brought to rest after the tires rotate through 40.2 turns.

a) What is the initial angular speed of the tires?

b) What is the angular acceleration of the tires?

c) What distance does the truck travel before coming to rest?

•**9.72** The motor of a fan turns a small wheel of radius $r_m = 2.00$ cm. This wheel turns a belt, which is attached to a wheel of radius $r_f = 3.00$ cm that is mounted to the axle of the fan blades. Measured from the center of this axle, the tip of the fan blades are at a distance $r_b = 15.0$ cm. When the fan is in operation, the motor spins at an angular speed of $\omega = 1200.$ rpm. What is the tangential speed of the tips of the fan blades?

•**9.73** A car with a mass of 1000. kg goes over a hill at a constant speed of 60.0 m/s. The top of the hill can be approximated as an arc length of a circle with a radius of curvature of 370. m. What force does the car exert on the hill as it passes over the top?

•**9.74** Unlike a ship, an airplane does not use its rudder to turn. It turns by banking its wings: The lift force, perpendicular to the wings, has a horizontal component, which provides the centripetal acceleration for the turn, and a vertical component, which supports the plane's weight. (The rudder counteracts yaw and thus it keeps the plane pointed in the direction it is moving.) A famous spy plane the SR-71 Blackbird, flying at 4800. km/h, had a turning radius of 290. km. Find its banking angle.

•**9.75** An 80.0-kg pilot in an aircraft moving at a constant speed of 500. m/s pulls out of a vertical dive along an arc of a circle of radius 4000. m.

a) Find the centripetal acceleration and the centripetal force acting on the pilot.

b) What is the pilot's apparent weight at the bottom of the dive?

•**9.76** A ball that has a mass of 1.00 kg is attached to a string 1.00 m long and is whirled in a vertical circle at a constant speed of 10.0 m/s.

a) Determine the tension in the string when the ball is at the top of the circle.

b) Determine the tension in the string when the ball is at the bottom of the circle.

c) Consider the ball at some point other than the top or bottom. What can you say about the tension in the string at this point?

•**9.77** A car starts from rest and accelerates around a flat curve of radius $R = 36.0$ m. The tangential component of the car's acceleration remains constant at $a_t = 3.30\ \text{m/s}^2$, while the centripetal acceleration increases to keep the car on the curve as long as possible. The coefficient of friction between the tires and the road is $\mu = 0.950$. What distance does the car travel around the curve before it begins to skid? (Be sure to include both the tangential and centripetal components of the acceleration.)

•**9.78** A girl on a merry-go-round platform holds a pendulum in her hand. The pendulum is 6.00 m from the rotation axis of the platform. The rotational speed of the platform is 0.0200 rev/s. It is found that the pendulum hangs at an angle θ to the vertical. Find θ.

••**9.79** A carousel at a carnival has a diameter of 6.00 m. The ride starts from rest and accelerates at a constant angular acceleration to an angular speed of 0.600 rev/s in 8.00 s.

a) What is the value of the angular acceleration?

b) What are the centripetal and angular accelerations of a seat on the carousel that is 2.75 m from the rotation axis?

c) What is the total acceleration, magnitude and direction, 8.00 s after the angular acceleration starts?

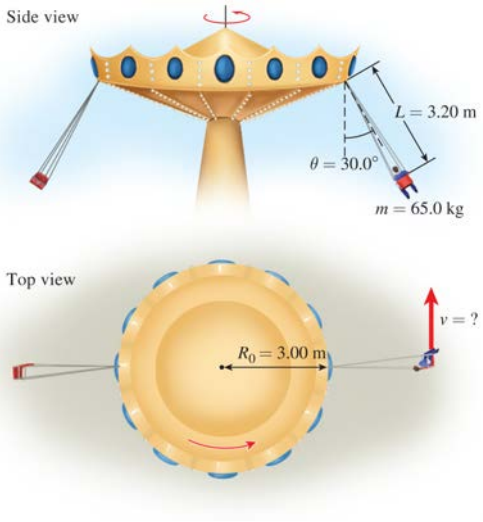
••**9.80** A car of weight $W = 10.0$ kN makes a turn on a track that is banked at an angle of $\theta = 20.0^\circ$. Inside the car, hanging from a short string tied to the rear-view mirror, is an ornament. As the car turns, the ornament swings out at an angle of $\varphi = 30.0^\circ$ measured from the vertical inside the car. What is the force of static friction between the car and the road?

••**9.81** A popular carnival ride consists of seats attached to a central disk through cables. The passengers travel in uniform circular

motion. As shown in the figure, the radius of the central disk is $R_0 = 3.00$ m, and the length of the cable is $L = 3.20$ m. The mass of one of the passengers (including the chair he is sitting on) is 65.0 kg.

a) If the angle θ that the cable makes with respect to the vertical is 30.0°, what is the speed, v, of this passenger?

b) What is the magnitude of the force exerted by the cable on the chair?



MULTI-VERSION EXERCISES

9.82 In the Thunder Sphere, a motorcycle moves on the inside of a sphere, traveling in a horizontal circle along the equator of the sphere. The inner radius of the sphere is 12.61 m, and the coefficient of static friction between the tires of the motorcycle and the inner surface of the sphere is 0.4601. What is the minimum speed the motorcycle must maintain to avoid falling?

9.83 In the Thunder Sphere, a motorcycle moves on the inside of a sphere, traveling in a horizontal circle along the equator of the sphere. The inner radius of the sphere is 13.75 m, and the motorcycle maintains a speed of 17.01 m/s. What is the minimum value for the coefficient of static friction between the tires of the motorcycle and the inner surface of the sphere to ensure that the motorcycle does not fall?

9.84 In the Thunder Sphere, a motorcycle moves on the inside of a sphere, traveling in a horizontal circle along the equator of the sphere. The motorcycle maintains a speed of 15.11 m/s, and the coefficient of static friction between the tires of the motorcycle and the inner surface of the sphere is 0.4741. What is the maximum radius that the sphere can have if the motorcycle is not to fall?

9.85 When the tips of the rotating blade of an airplane propeller have a linear speed greater than the speed of sound, the propeller makes a lot of noise, which is undesirable. If the blade turns at 2403 rpm, what is the maximum length it can have without the tips exceeding the speed of sound? Assume that the speed of sound is 343.0 m/s and that the blade rotates about its center.

9.86 When the tips of the rotating blade of an airplane propeller have a linear speed greater than the speed of sound, the propeller makes a lot of noise, which is undesirable. If the tip-to-tip length of the blade is 2.601 m, what is the maximum angular frequency (in revolutions per minute) with which it can rotate? Assume that the speed of sound is 343.0 m/s and that the blade rotates about its center.

9.87 The rear wheels of a sports car have a radius of 46.65 cm. The sports car goes from rest to a speed of 29.13 m/s in 3.945 s with constant acceleration. What is the angular acceleration of the rear wheels? Assume that the wheels roll without slipping.

9.88 The rear wheels of a sports car have a radius of 48.95 cm. The sports car accelerates from rest with constant acceleration for 3.997 s. The angular acceleration of the rear wheels is 14.99 s^{-2}. What is the final linear speed of the car? Assume that the wheels roll without slipping.

9.89 A sports car accelerates from rest to a speed of 29.53 m/s with constant acceleration in 4.047 s. The angular acceleration of the rear wheels is 17.71 s^{-2}. What is the radius of the rear wheels? Assume that the wheels roll without slipping.

9.90 A flywheel of radius 27.01 cm rotates with a frequency of 4949 rpm. What is the centripetal acceleration at a point on the edge of the flywheel?

9.91 A flywheel of radius 31.59 cm is rotating at a constant frequency. The centripetal acceleration at a point on the edge of the flywheel is $8.629 \cdot 10^4$ m/s^2. What is the frequency of rotation of the flywheel (in rpm)?

The large fans at the front of modern jet engines, like the one shown in Figure 10.1, pull air into a compression chamber, where the air mixes with fuel and ignites. The explosion propels gases out the back of the engine, producing the thrust that moves the plane forward. These fans rotate at 7000–9000 rpm and must be inspected often—no one wants a broken fan blade at an altitude of 6 mi.

FIGURE 10.1 A modern jet engine.

Alhim/Shutterstock

Almost all engines have rotating parts that transfer energy to the output device, which is often rotating as well. In fact, most objects in the universe rotate, from molecules to stars and galaxies. Figure 10.2 shows rotation on very large (a hurricane) and humongous (a spiral galaxy) scales. Furthermore, in 2011, a team including five undergraduates from the University of Michigan analyzed a large sample of galaxies and found evidence that the universe as a whole rotates. The laws that govern rotation are as fundamentally important as any other part of mechanics.

Chapter 9 introduced some basic concepts of circular motion, and this chapter uses some of those same ideas—angular velocity, angular acceleration, and axis of rotation. In this chapter, we complete our comparison of translational and rotational quantities and encounter another conservation law of basic importance: the law of conservation of angular momentum.

WHAT WE WILL LEARN

- The kinetic energy due to an object's rotational motion must be accounted for when considering energy conservation.
- For rotation of a round object about an axis through its center of mass, the moment of inertia is proportional to the product of the object's mass and the square of the largest perpendicular distance from any part of the object to the axis of rotation. The proportionality constant has a value between zero and one and depends on the shape of the object.
- For rotation about an axis parallel to an axis through an object's center of mass, the moment of inertia equals the center-of-mass moment of inertia plus the product of the mass of the object and the square of the distance between the two axes.
- For rolling objects, the kinetic energies of rotation and translation are related.
- Torque is the vector product of the position vector and the force vector.
- Newton's Second Law also applies to rotational motion.
- Angular momentum is defined as the vector product of the position vector and the momentum vector.
- Relationships analogous to those for linear quantities exist among angular momentum, torque, moment of inertia, angular velocity, and angular acceleration.
- Another fundamental conservation law is the law of conservation of angular momentum.

10.1 Kinetic Energy of Rotation

In Chapter 8, we saw that we can describe the motion of an extended object in terms of the path that its center of mass follows and the rotation of the object around its center of mass. However, even though we covered circular motion for point particles in Chapter 9, we have not yet considered the rotation of extended objects. Analyzing this motion is the purpose of this chapter.

Point Particle in Circular Motion

Chapter 9 introduced the kinematical quantities of circular motion. Angular speed, ω, and angular acceleration, α, were defined in terms of the time derivatives of the angular displacement, θ:

$$\omega = \frac{d\theta}{dt}$$
$$\alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}.$$

We saw that the angular quantities are related to the linear quantities as follows:

$$s = r\theta, \;\; v = r\omega,$$
$$a_{\mathrm{t}} = r\alpha, \; a_{\mathrm{c}} = \omega^2 r, \; a = \sqrt{a_{\mathrm{c}}^2 + a_{\mathrm{t}}^2},$$

where s is the arc length, v is the linear speed of the center of mass, a_{t} is the tangential acceleration, a_{c} is the centripetal acceleration, and a is the linear acceleration.

The most straightforward way to introduce the physical quantities for the description of rotation is through the kinetic energy of rotation of an extended object. In Chapter 5 on work and energy, the kinetic energy of a moving object was defined as

$$K = \tfrac{1}{2}mv^2. \qquad \textbf{(10.1)}$$

If the motion of this object is circular, we can use the relationship between linear and angular velocity to obtain

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m(r\omega)^2 = \tfrac{1}{2}mr^2\omega^2, \qquad \textbf{(10.2)}$$

which is the **kinetic energy of rotation** for a point particle's motion on the circumference of a circle of radius r about a fixed axis, as illustrated in Figure 10.3.

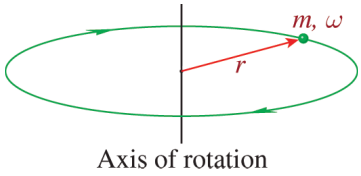

FIGURE 10.3 A point particle moving in a circle about the axis of rotation.

Several Point Particles in Circular Motion

Just as we proceeded in Chapter 8 in finding the location of the center of mass of a system of particles, we start with a collection of individual rotating objects and then approach the continuous limit. The kinetic energy of a collection of rotating objects is given by

$$K = \sum_{i=1}^{n} K_i = \tfrac{1}{2} \sum_{i=1}^{n} m_i v_i^2 = \tfrac{1}{2} \sum_{i=1}^{n} m_i r_i^2 \omega_i^2.$$

This result is simply a consequence of using equation 10.2 for several point particles and writing the total kinetic energy as the sum of the individual kinetic energies. Here ω_i is the angular velocity of particle i and r_i is the perpendicular distance from i to a fixed axis. This fixed axis is the **axis of rotation** for these particles. An example of a system of five rotating point particles is shown in Figure 10.4.

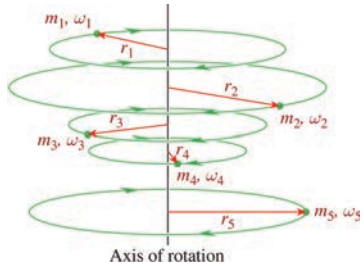

FIGURE 10.4 Five point particles moving in circles about a common axis of rotation.

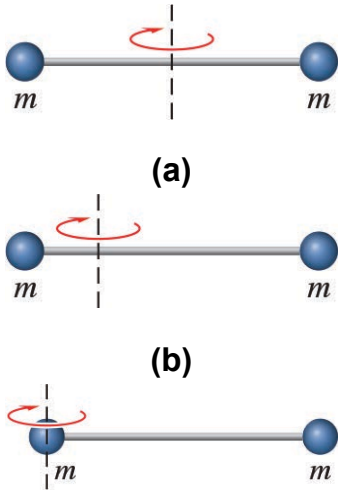
Now we assume that all of the point particles whose kinetic energies we have summed keep their distances with respect to one another and with respect to the axis of rotation fixed. Then, all of the point particles in the system will undergo circular motion around the common axis of rotation with the same angular

velocity. With this constraint, the sum of the particles' kinetic energies becomes

$$K = \tfrac{1}{2}\sum_{i=1}^{n} m_i r_i^2 \omega^2 = \tfrac{1}{2}\left(\sum_{i=1}^{n} m_i r_i^2\right)\omega^2 = \tfrac{1}{2} I\omega^2. \quad \textbf{(10.3)}$$

Concept Check 10.1

Consider two equal masses, *m*, connected by a thin, massless rod. As shown in the figures, the two masses spin in a horizontal plane around a vertical axis represented by the dashed line. Which system has the highest moment of inertia?



The quantity *I* introduced in equation 10.3 is called the **moment of inertia,** also known as the *rotational inertia*. It depends only on the masses of the individual particles and their distances to the axis of rotation:

$$I = \sum_{i=1}^{n} m_i r_i^2. \qquad \textbf{(10.4)}$$

In Chapter 9, we saw that all quantities associated with circular motion have equivalents in linear motion. The angular velocity ω and the linear velocity v form such a pair. Comparing the expressions for the kinetic energy of rotation (equation 10.3) and the kinetic energy of linear motion (equation 10.1), we see that the moment of inertia I plays the same role for circular motion as the mass m does for linear motion.

10.2 Calculation of Moment of Inertia

We can use the moment of inertia of several point particles, as given in equation 10.4, as a starting point to find the moment of inertia of an extended object. We'll proceed in the same way as we did in finding the center-of-mass location in Chapter 8. We again represent an extended object by a collection of small identical-sized cubes of volume V and (possibly different) mass density ρ. Then equation 10.4 becomes

$$I = \sum_{i=1}^{n} \rho\left(\overrightarrow{r_i}\right) r_i^2 V. \qquad \textbf{(10.5)}$$

Again, as in Chapter 8, we follow the conventional calculus approach, letting the volume of the cubes approach zero, $V \to 0$. In this limit, the sum in equation 10.5 approaches the integral, which gives an expression for the moment of inertia of an extended object:

$$I = \int_V r_\perp^2 \rho\left(\overrightarrow{r}\right) dV. \qquad \textbf{(10.6)}$$

The symbol $r_\perp$ represents the perpendicular distance of an infinitesimal volume element from the axis of rotation (Figure 10.5).

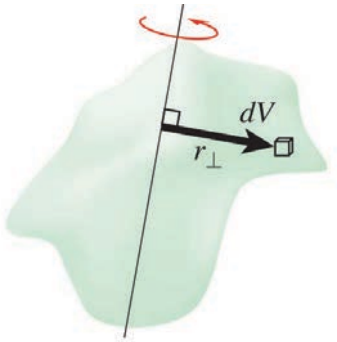


FIGURE 10.5
Definition of $r_\perp$ as the perpendicular distance of an infinitesimal volume element from the axis of rotation.

We also know that the total mass of an object can be obtained by integrating the mass density over the total volume of the object:

$$M = \int_V \rho\left(\vec{r}\right) dV. \qquad \textbf{(10.7)}$$

Equations 10.6 and 10.7 are the most general expressions for the moment of inertia and the mass of an extended object. However, just as with the equations for the center of mass, some of the physically most interesting cases are those where the mass density is constant throughout the volume. In this case, equations 10.6 and 10.7 reduce to

$$I = \rho \int_v r_\perp^2 \, dV \quad \text{(for constant mass density, } \rho\text{)},$$

and

$$M = \rho \int_V dV = \rho V \quad (\text{for constant mass density}, \rho).$$

Thus, the moment of inertia for an object with constant mass density is given by

$$I = \frac{M}{V} \int_V r_\perp^2 dV \quad (\text{for constant mass density}, \rho). \tag{10.8}$$

We can now calculate moments of inertia for some objects with particular shapes. First we'll assume that the axis of rotation passes through the center of mass of the object. Then, we'll derive a theorem that connects this special case in a simple way to the general case, for which the axis of rotation does not pass through the center of mass.

Rotation about an Axis through the Center of Mass

For any object with constant mass density, we can use equation 10.8 to calculate the moment of inertia with respect to rotation about a fixed axis that passes through the object's center of mass. For convenience, the location of the center of mass is usually chosen as the origin of the coordinate system. Because the integral in equation 10.8 is a three-dimensional volume integral, the choice of coordinate system is usually extremely important for evaluating the integral with as little computational work as possible.

In this section, we consider two cases: a hollow cylinder and a solid sphere. These cases represent the two most common classes of objects that can roll, and they illustrate the use of two different coordinate systems for the integral.

Figure 10.6a shows a hollow cylinder rotating about its symmetry axis. Its moment of inertia is

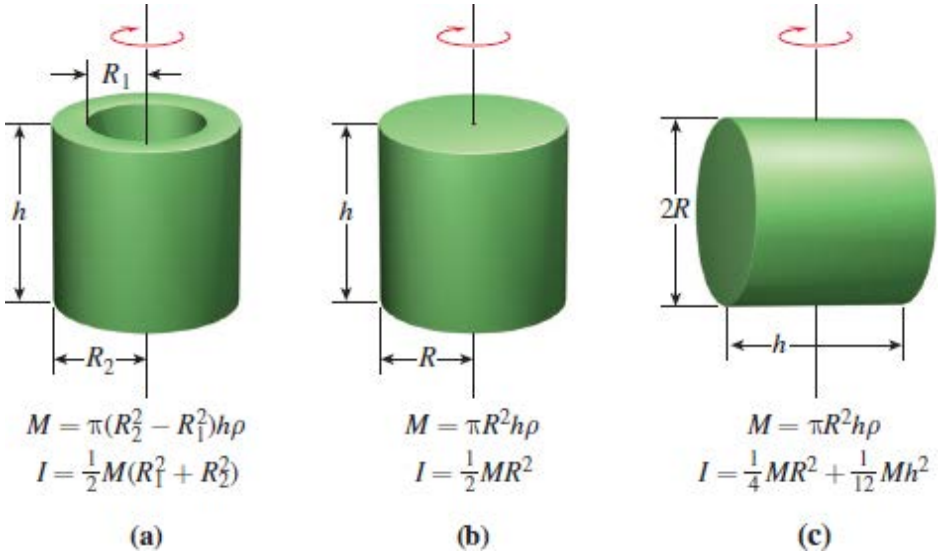

FIGURE 10.6 Moment of inertia for (a) a hollow cylinder and (b) a solid cylinder rotating about the axis of symmetry. (c) Moment of inertia for a cylinder rotating about an axis through its center of mass but perpendicular to its symmetry axis.

$$I = \frac{1}{2}M\left(R_1^2 + R_2^2\right) \text{ (hollow cylinder).} \qquad \textbf{(10.9)}$$

This is the general result for the moment of inertia of a hollow cylinder rotating about its symmetry axis, where M is the cylinder's total mass, R_1 is its inner radius, and R_2 is its outer radius.

Using equation 10.9, we can obtain the moment of inertia for a solid cylinder rotating about its symmetry axis (see Figure 10.6b) by setting $R_1 = R$ and $R_2 = 0$:

$$I = \frac{1}{2}MR^2 \text{ (soild cylindrical).}$$

We can also obtain the limiting case of a thin cylindrical shell or hoop, for which all the mass is concentrated on the circumference, by setting $R_1 = R_2 = R$. In this case, the moment of inertia is

$$I = MR^2 \text{ (hoop or cylindrical thin shell).}$$

Finally, the moment of inertia for a solid cylinder of height h rotating about an axis throug hits center of mass but perpendicular to its symmetry axis (see Figure 10.6c) is given by

$$I = \frac{1}{4}MR^2 + \frac{1}{12}Mh^2 \text{ (solid cylinder, perpendiculer to axi}$$

If the radius R is very small compared to the height h, as is the case for a long thin rod, the moment of inertia in that limit is given by dropping the first term of the preceding equation:

$$I = \frac{1}{12}Mh^2 \text{ (thin rod of length } h\text{, perpendicular to axis of}$$

We'll derive the formula for the moment of inertia of the hollow cylinder using a volume integral of the kind introduced in Section 8.4. This integral involves separate one-dimensional integrations over each of the three coordinates. This derivation and the next one show how these integrations are done for cylindrical and spherical coordinates. They are not essential for the physical concepts developed in this chapter, but they may be interesting to you.

DERIVATION 10.1 Moment of Inertia for a Wheel

In order to derive the moment of inertia of a hollow cylinder of constant density ρ, height h, inner radius R_1, and outer radius R_2, with its symmetry axis as the axis of rotation (see Figure 10.6a), we'll use cylindrical coordinates. For most problems involving cylinders or disks, the coordinate system chosen should generally be cylindrical. In this system (see the discussion of volume integrals in Section 8.4), the volume element is given by (see Figure 10.7).

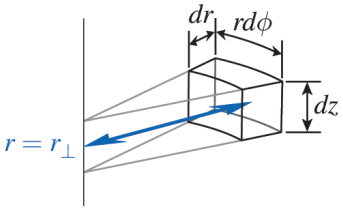

FIGURE 10.7
Volume element in cylindrical coordinates.

$$dV = r_\perp dr_\perp d\phi dz.$$

For cylindrical coordinates (and only for cylindrical coordinates!), the perpendicular distance, $r_\perp$, is the same as the radial coordinate, r. With this in mind, we can evaluate the integrals for the hollow cylinder. For the mass, we obtain

$$
\begin{aligned}
M &= \rho \int_V dV = \rho \int_{R_1}^{R_2} \left(\int_0^{2\pi} \left(\int_{-h/2}^{h/2} dz \right) d\phi \right) r_\perp dr_\perp \\
&= \rho h \int_{R_1}^{R_2} \left(\int_0^{2\pi} d\phi \right) r_\perp dr_\perp \\
&= \rho h 2\pi \int_{R_1}^{R_2} r_\perp dr_\perp \\
&= \rho h 2\pi \left(\tfrac{1}{2} R_2^2 - \tfrac{1}{2} R_1^2 \right) \\
&= \pi \left(R_2^2 - R_1^2 \right) h \rho .
\end{aligned}
$$

Alternatively, we can express the density as a function of the mass:

$$
M = \pi \left(R_2^2 - R_1^2 \right) h \rho \Leftrightarrow \rho = \frac{M}{\pi \left(R_2^2 - R_1^2 \right) h} . \quad \text{(i)}
$$

The reason for performing this last step may not be entirely obvious right now, but it should become clear after we evaluate the integral for the moment of inertia:

$$
\begin{aligned}
I &= \rho \int_V r_\perp^2 \, dV = \rho \int_{R_1}^{R_2} \left(\int_0^{2\pi} \left(\int_{-h/2}^{h/2} dz \right) d\phi \right) r_\perp^3 \, dr_\perp \\
&= \rho h \int_{R_1}^{R_2} \left(\int_0^{2\pi} d\phi \right) r_\perp^3 \, dr_\perp \\
&= \rho h 2\pi \int_{R_1}^{R_2} r_\perp^3 \, dr_\perp \\
&= \rho h 2\pi \left(\tfrac{1}{4} R_2^4 - \tfrac{1}{4} R_1^4 \right).
\end{aligned}
$$

Now we can substitute for the density from equation (i):

$$
I = \tfrac{1}{2} \rho h \pi \left(R_2^4 - R_1^4 \right) = \frac{M}{\pi \left(R_2^2 - R_1^2 \right) h} \tfrac{1}{2} h \pi \left(R_2^4 - R_1^4 \right).
$$

Finally, we make use of the identity $a^4 - b^4 = \left(a^2 - b^2 \right) \left(a^2 + b^2 \right)$ to obtain equation 10.9:

$$
I = \tfrac{1}{2} M \left(R_1^2 + R_2^2 \right).
$$

For objects other than disklike ones, the use of cylindrical coordinates may not be advantageous. The most important such objects are spheres and rectangular blocks. The moment of inertia for a sphere rotating about any axis through its center of mass (see Figure 10.8a) is given by

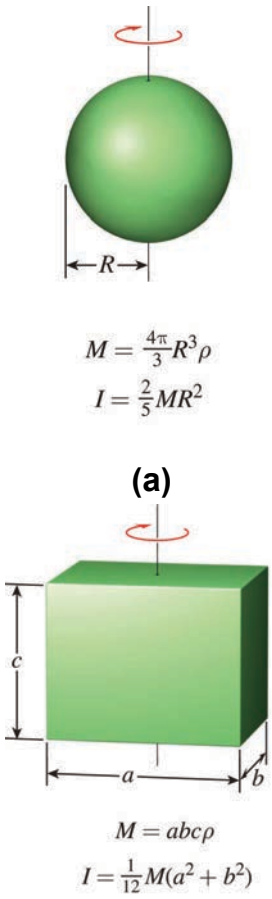

FIGURE 10.8 Moments of inertia of (a) a sphere and (b) a block.

$$I = \tfrac{2}{5}MR^2 \ \text{(solid sphere)}. \qquad \textbf{(10.10)}$$

The moment of inertia for a thin spherical shell rotating about any axis through its center of mass is

$$I = \tfrac{2}{3}MR^2 \ \text{(thin spherical shell)}.$$

The moment of inertia for a rectangular block with side lengths a, b, and c rotating about an axis through the center of mass and

parallel to side c (see Figure 10.8b) is

$$I = \tfrac{1}{12} M\left(a^2 + b^2\right) \text{ (rectangular block).}$$

Again, we'll derive the formula for the solid sphere only in order to illustrate working in a different coordinate system.

DERIVATION 10.2 Moment of Inertia for a Sphere

To calculate the moment of inertia for a solid sphere (Figure 10.8a) of constant mass density ρ and radius R rotating about an axis through its center, it is not appropriate to use cylindrical coordinates. Spherical coordinates are the best choice. In spherical coordinates, the volume element is given by (see Figure 10.9)

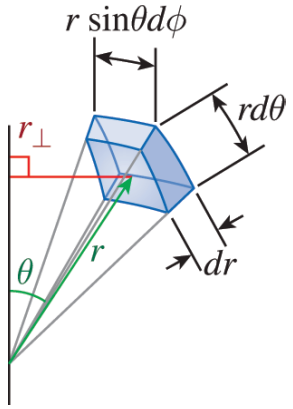

FIGURE 10.9
Volume element in spherical coordinates.

$$dV = r^2 \sin\theta \, dr \, d\theta \, d\phi.$$

Note that for spherical coordinates, the radial coordinate, r, and the perpendicular distance, $r_\perp$, are not identical. Instead, they are related via (see Figure 10.9)

$$r_\perp = r \sin\theta.$$

(It is a very common source of error in these kinds of calculations to omit the sine of the angle. You need to keep this in mind when you are using spherical coordinates.)

Again, we first evaluate the integral for the mass:

$$\begin{aligned} M &= \rho \int_V dV = \rho \int_0^R \left(\int_0^{2\pi} \left(\int_0^{\pi} \sin\theta \, d\theta \right) d\phi \right) r^2 dr \\ &= 2\rho \int_0^R \left(\int_0^{2\pi} d\phi \right) r^2 dr = 4\pi\rho \int_0^R r^2 dr \\ &= \frac{4\pi}{3} R^3 \rho. \end{aligned}$$

Thus,

$$\rho = \frac{3M}{4\pi R^3}. \qquad \text{(i)}$$

Then we evaluate the integral for the moment of inertia in a similar way:

$$\begin{aligned} I &= \rho \int_V r_\perp^2 dV = \rho \int_V r^2 \sin^2\theta \, dV \\ &= \rho \int_0^R \left(\int_0^{2\pi} \left(\int_0^{\pi} \sin^3\theta \, d\theta \right) d\phi \right) r^4 dr = \rho \frac{4}{3} \int_0^R \left(\int_0^{2\pi} d\phi \right) \\ &= \rho \frac{8\pi}{3} \int_0^R r^4 dr. \end{aligned}$$

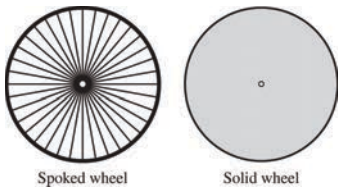
Thus,

$$I = \rho \frac{8\pi}{15} R^5. \qquad \text{(ii)}$$

Inserting the expression for the density from equation (i) into equation (ii) we obtain

$$I = \rho \frac{8\pi}{15} R^5 = \frac{3M}{4\pi R^3} \frac{8\pi}{15} R^5 = \tfrac{2}{5} M R^2.$$

Concept Check 10.2



The two bicycle wheels shown each have the same mass and the same radius and rotate about their center of mass. One wheel has spokes and most of the mass of the wheel is near the outer radius of the wheel. The other wheel is a uniform solid disk. What can we say about the moment of inertia of the two wheels?

a) The spoked wheel has the smallest moment of inertia.

b) The solid wheel has the smallest moment of inertia.

c) The spoked wheel and the solid wheel have the same moment of inertia.

Finally, note this important general observation: If R is the largest perpendicular distance of any part of the rotating object

from the axis of rotation, then the moment of inertia is always related to the mass of an object by

$$I = cMR^2, \text{ With } 0 < c \leq 1. \qquad \textbf{(10.11)}$$

The constant c can be calculated from the geometrical configuration of the rotating object and always has a value between zero and one. The more the bulk of the mass is pushed toward the axis of rotation, the smaller the value of the constant c will be. If all the mass is located on the outer edge of the object, as in a hoop, for example, then c approaches the value 1. (Mathematically, this equation is a consequence of the mean value theorem, which you may have encountered in a calculus class.) For a cylinder rotating around its symmetry axis, $C_{\text{cyl}} = \frac{1}{2}$, and for a sphere, $C_{\text{sph}} = \frac{2}{5}$, as we have seen.

Various objects rotating about an axis that passes through the center of mass are shown in Figure 10.10. Table 10.1 gives the moment of inertia for each object as well as the constant c from equation 10.11, where applicable.

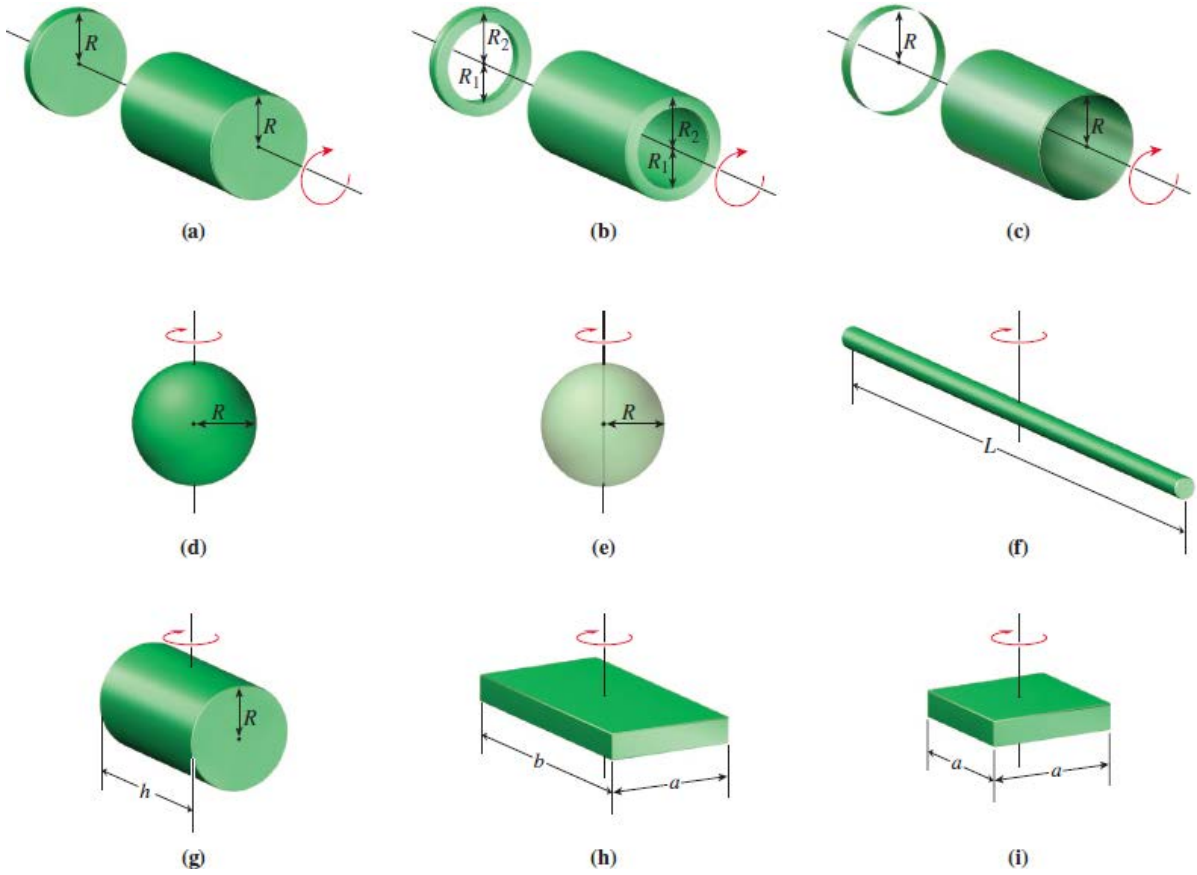


FIGURE 10.10 Orientation of the axis of rotation passing through the center of mass and definition of dimensions for objects listed in Table 10.1.

Table 10.1 **The Moment of Inertia and Value of Constant *c* for the Objects Shown in Figure 10.10. All Objects Have Mass *M***

Object		*I*	*c*
a)	Solid cylinder or disk	$\frac{1}{2}MR^2$	$\frac{1}{2}$
b)	Thick hollow cylinder or wheel	$\frac{1}{2}M\left(R_1^2+R_2^2\right)$	
c)	Hollow cylinder or hoop	MR^2	1
d)	Solid sphere	$\frac{2}{5}MR^2$	$\frac{2}{5}$
e)	Hollow sphere	$\frac{2}{3}MR^2$	$\frac{2}{3}$
f)	Thin rod	$\frac{1}{12}ML^2$	
g)	Solid cylinder perpendicular to symmetry axis	$\frac{1}{4}MR^2+\frac{1}{12}Mh^2$	
h)	Flat rectangular plate	$\frac{1}{12}M\left(a^2+b^2\right)$

EXAMPLE 10.1 Rotational Kinetic Energy of Earth

Assume that the Earth is a solid sphere of constant density, with mass $5.98 \cdot 10^{24}$ kg and radius 6370 km.

PROBLEM

What is the moment of inertia of the Earth with respect to rotation about its axis, and what is the kinetic energy of this rotation?

SOLUTION

Since the Earth is to be approximated by a sphere of constant density, its moment of inertia is

$$I = \tfrac{2}{5} M R^2.$$

Inserting the values for the mass and the radius, we obtain

$$I = \tfrac{2}{5} M R^2 = \tfrac{2}{5} \left(5.98 \cdot 10^{24}\ \text{kg}\right) \left(6.37 \cdot 10^{6}\ \text{m}\right)^2 = 9.71 \cdot 1$$

The angular frequency of Earth's rotation is

$$\omega = \frac{2\pi}{1\ \text{day}} = \frac{2\pi}{86,164\ \text{s}} = 7.29 \cdot 10^{-5}\ \text{rad/s}.$$

(Note that we used the sidereal day here; see Example 9.3.)

With the results for the moment of inertia and the angular frequency, we can find the kinetic energy of the Earth's rotation:

$$K = \tfrac{1}{2} I \omega^2 = 0.5 \left(9.71 \cdot 10^{37}\ \text{kg m}^2\right) \left(7.29 \cdot 10^{-5}\ \text{rad/s}\right)^2$$

Let's compare this to the kinetic energy of Earth's motion around the Sun. In Chapter 9, we calculated the orbital speed

of Earth to be $v = 2.97 \cdot 10^4$ m/s. Thus, the kinetic energy of Earth's motion around the Sun is

$$K = \tfrac{1}{2}mv^2 = 0.5\left(5.98 \cdot 10^{24}\ \text{kg}\right)\left(2.97 \cdot 10^4\ \text{m/s}\right)^2 = 2.6$$

which is larger than the kinetic energy of rotation by a factor greater than 10,000.

Parallel-Axis Theorem

We have determined the moment of inertia for a rotation axis through the center of mass of an object, but what is the moment of inertia for rotation about an axis that does not pass through the center of mass? The **parallel-axis theorem** answers this question. It states that the moment of inertia, $I_{\parallel}$, for rotation of an object of mass M about an axis located a distance d away from the object's center of mass and parallel to an axis through the center of mass, for which the moment of inertia is I_{cm}, is given by

$$I_{\parallel} = I_{\text{cm}} + Md^2. \qquad \textbf{(10.12)}$$

DERIVATION 10.3 Parallel-Axis Theorem

For this derivation, consider the object in Figure 10.11. Suppose we have already calculated the moment of inertia of this object for rotation about the z-axis, which passes through the center of mass of this object. The origin of the xyz-coordinate system is at the center of mass, and the z-axis is the rotation axis. Any axis parallel to the rotation axis can then be described by a simple shift in the xy-plane indicated in the figure by the vector $\vec{d}$, with components d_x and d_y.

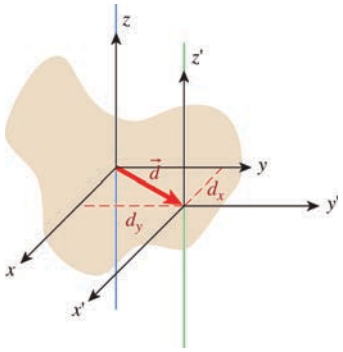

FIGURE 10.11 Coordinates and distances for the parallel-axis theorem.

If we shift the coordinate system in the xy-plane so that the new vertical axis, the z'-axis, coincides with the new rotation axis, then the transformation from the xyz-coordinates to the new $x'y'z'$-coordinates is given by

$$x\prime = x - d_x, \quad y\prime = y - d_y, \quad z\prime = z.$$

To calculate the moment of inertia of the object rotating about the new axis in the new coordinate system, we can simply use equation 10.6, the most general equation, which applies to the case where the mass density is not constant:

$$I_{\parallel} = \int_V (r_{\perp\prime})^2 \rho \, dV. \qquad \text{(i)}$$

According to the coordinate transformation,

$$\begin{aligned}(r_{\perp\prime})^2 &= (x')^2 + (y')^2 = (x - d_x)^2 + (y - d_y)^2 \\ &= x^2 - 2xd_x + d_x^2 + y^2 - 2yd_y + d_y^2 \\ &= \left(x^2 + y^2\right) + \left(d_x^2 + d_y^2\right) - 2xd_x - 2yd_y \\ &= r_{\perp}^2 + d^2 - 2xd_x - 2yd_y.\end{aligned}$$

(Keep in mind that $\overrightarrow{r_{\perp}}$ lies in the *xy*-plane because of the way we constructed the coordinate system.) Now we substitute this expression for $(r_{\perp\prime})^2$ into equation (i) and obtain

$$\begin{aligned}I_{\parallel} &= \int_V (r_{\perp\prime})^2 \rho \; dV \\ &= \int_V r_{\perp}^2 \rho \, dV + d^2 \int_V \rho \, dV - 2d_x \int_V x\rho \, dV - 2d_y \int_V\end{aligned}$$

The first integral in equation (ii) gives the moment of inertia for rotation about the center of mass, which we already know. The second integral is simply equal to the mass (compare to equation 10.7). The third and fourth integrals were introduced in Chapter 8 and give the locations of the *x*- and *y*-coordinates of the center of mass when divided by the mass. However, by construction, they equal zero, because we put the origin of the

xyz-coordinate system at the center of mass. Thus, we obtain the parallel-axis theorem:

$$I_{\parallel} = I_{\text{cm}} + d^2 M.$$

Note that, according to equations 10.11 and 10.12, the moment of inertia with respect to rotation about an arbitrary axis parallel to an axis through the center of mass can be written as

$$I = \left(cR^2 + d^2\right) M, \text{ with } 0 < c \leq 1.$$

Here R is the maximum perpendicular distance of any part of the object from its axis of rotation through the center of mass, and d is the distance of the rotation axis from a parallel axis through the center of mass.

Self-Test Opportunity 10.1

Show that the moment of inertia of a thin rod of mass m and length L rotating around one end is $I = \frac{1}{3} mL^2$.

10.3 Rolling without Slipping

Rolling motion is a special case of rotational motion that is performed by round objects of radius R that move across a surface without slipping. For rolling motion, we can connect the linear and angular quantities by realizing that the linear distance moved by the center of mass is the same as the length of corresponding arc of the object's circumference, as shown in Table 9.1. Thus, the relationship between the linear displacement, x, of the center of mass and the rotation angle is

$$x = R\theta.$$

Taking the time derivative and keeping in mind that the radius, R, remains constant, we obtain the relationships between linear and angular speeds and accelerations:

$$v = R\omega$$

and

$$a = R\alpha.$$

The total kinetic energy of an object in rolling motion is the sum of its translational (linear motion of its center of mass) and rotational kinetic energies (rotation about the center of mass):

$$K = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2. \qquad \textbf{(10.13)}$$

We can now substitute for ω from $v = R\omega$ and for I from equation 10.11:

$$\begin{aligned} K &= \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 \\ &= \frac{1}{2}mv^2 + \frac{1}{2}\left(cR^2m\right)\left(\frac{v}{R}\right)^2 \\ &= \frac{1}{2}mv^2 + \frac{1}{2}mv^2c \Rightarrow \\ K &= (1+c)\frac{1}{2}mv^2, \end{aligned} \qquad \textbf{(10.14)}$$

Concept Check 10.3

A solid sphere, a solid cylinder, and a hollow cylinder have the same mass and radius and are rolling with the same speed. Which one of the following statements is true?

a) The solid sphere has the highest kinetic energy.

b) The solid cylinder has the highest kinetic energy.

c) The hollow cylinder has the highest kinetic energy.

d) All three objects have the same kinetic energy.

where $0 < c \leq 1$ is the constant introduced in equation 10.11. Equation 10.14 implies that the kinetic energy of a rolling object is always greater than that of an object that is sliding, provided they have the same mass and linear velocity.

With an expression for the kinetic energy that includes the contribution due to rotation, we can apply the concept of conservation of total mechanical energy (the sum of kinetic and potential energy) that we applied in Chapter 6.

SOLVED PROBLEM 10.1 Sphere Rolling Down an Inclined Plane

PROBLEM

A solid sphere with a mass of 5.15 kg and a radius of 0.340 m starts from rest at a height of 2.10 m above the base of an inclined plane and rolls down without sliding under the influence of gravity. What is the linear speed of the center of mass of the sphere just as it leaves the incline and rolls onto a horizontal surface?

SOLUTION

THINK

At the top of the incline, the sphere is at rest. At that point, the sphere has gravitational potential energy and no kinetic energy. As the sphere starts to roll, it loses potential energy and gains kinetic energy of linear motion and kinetic energy of rotation. At the bottom of the inclined plane, all of the original potential energy is in the form of kinetic energy. The kinetic energy of linear motion is linked to the kinetic energy of rotation through the radius of the sphere.

SKETCH

A sketch of the problem situation is shown in Figure 10.12 with the zero of the y-coordinate at the bottom of the incline.

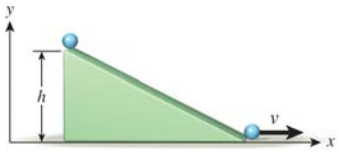

FIGURE 10.12
Sphere rolling down an inclined plane.

RESEARCH

At the top of the incline, the sphere is at rest and has zero kinetic energy. At the top, its energy is therefore its potential

energy, mgh:

$$E_{\text{top}} = K_{\text{top}} + U_{\text{top}} = 0 + mgh = mgh,$$

where m is the mass of the sphere, h is the height of the sphere above the horizontal surface, and g is the acceleration due to gravity. At the bottom of the incline, just as the sphere starts rolling onto the horizontal surface, the potential energy is zero. According to equation 10.14, the sphere has a total kinetic energy (sum of translational and rotational kinetic energy) of $(1 + c)\frac{1}{2}mv^2$. Thus, the total energy at the bottom of the incline is

$$E_{\text{bottom}} = K_{\text{bottom}} + U_{\text{bottom}} = (1 + c)\tfrac{1}{2}mv^2 + 0 = (1 +$$

Because the moment of inertia of a sphere is $I = \frac{2}{5}mR^2$ (see equation 10.10), the constant c has the value $\dfrac{2}{5}$ in this case.

SIMPLIFY

Because of the conservation of energy, the energy at the top of the incline is equal to that at the bottom:

$$mgh = (1 + c)\tfrac{1}{2}mv^2.$$

Solving for the linear velocity gives us

$$v = \sqrt{\frac{2gh}{1 + c}}.$$

For a sphere, $c = \dfrac{2}{5}$, as noted above, and so the speed of the rolling object is in this case

$$v = \sqrt{\frac{2gh}{1 + \dfrac{2}{5}}} = \sqrt{\frac{10}{7}gh}.$$

CALCULATE

Putting in the numerical values gives us

$$v = \sqrt{\frac{10}{7}(9.81\ \text{m/s}^2)(2.10\ \text{m})} = 5.42494\ \text{m/s}.$$

ROUND

Expressing our result with three significant figures leads to

$$v = 5.42\ \text{m/s}.$$

DOUBLE-CHECK

If the sphere did not roll, but instead slid down the inclined plane without friction, the final speed would be

$$v = \sqrt{2gh} = \sqrt{2(9.81\ \text{m/s}^2)(2.10\ \text{m})} = 6.42\ \text{m/s},$$

which is faster than the speed we found for the rolling sphere. It seems reasonable that the final linear velocity of the rolling sphere is somewhat less than the final linear velocity of the sliding sphere, because some of the initial potential energy of the rolling sphere is transformed into rotational kinetic energy. This energy is then not available to become kinetic energy of linear motion of the center of mass of the sphere. Note that we did not need the mass or radius of the sphere in this calculation.

The formula derived in Solved Problem 10.1 for the speed of a rolling sphere at the bottom of the incline,

$$v = \sqrt{\frac{2gh}{1+c}}, \qquad \textbf{(10.15)}$$

is a rather general result. It can be applied to various situations in which potential gravitational energy is converted into translational and rotational kinetic energy of a rolling object.

Galileo Galilei famously showed that the acceleration of an object in free fall is independent of its mass. This is also true for an object rolling down an incline, as we have just seen in Solved Problem 10.1, leading to equation 10.15. However, while the total mass of the rolling object does not matter, the distribution of mass within it does matter. Mathematically, this is reflected in equation 10.15 by the fact that the constant c from equation 10.11, which is calculated from the geometric distribution of the mass, appears in the denominator. The following example demonstrates clearly that the distribution of mass in rolling objects matters.

Concept Check 10.4

Suppose we repeat the race of Example 10.2, but let an unopened can of soda participate. In which place will the can finish?

a) first

b) second

c) third

d) fourth

EXAMPLE 10.2 Race Down an Incline

PROBLEM

A solid sphere, a solid cylinder, and a hollow cylinder (a tube), all of the same mass m and the same outer radius R, are released from rest at the top of an incline and start rolling without sliding. In which order do they arrive at the bottom of the incline?

SOLUTION

We can answer this question by using energy considerations only. Since the total mechanical energy is conserved for each of the three objects during its rolling motion, we can write for each object

$$E = K + U = K_0 + U_0.$$

The objects were released from rest, so $K_0 = 0$. For the potential energy, we again use $U = mgh$, and for the kinetic energy, we use equation 10.14. Therefore, we have

$$K_{\text{bottom}} = U_{\text{top}} \Rightarrow (1 + c)\tfrac{1}{2}mv^2 = mgh \Rightarrow$$
$$v = \sqrt{\frac{2gh}{1 + c}},$$

which is the same formula as equation 10.15.

We already noted that the mass and radius of the object canceled out of this formula. However, we can make an additional important observation. The constant c that is determined by the distribution of the mass appears in the denominator. We already know the value of c for the three rolling objects: $c_{\text{sphere}} = \frac{2}{5}$, $c_{\text{cylinder}} = \frac{1}{2}$, and $c_{\text{tube}} \approx 1$. Since the constant for the sphere is the smallest, the sphere's velocity

for any given height h will be the largest, implying that the sphere will win the race. Physically, we see that since all three objects have the same mass and thus have the same change in potential energy, all final kinetic energies are equal. Thus, an object with a higher value of c will have relatively more of its kinetic energy in rotation and therefore a lower translational kinetic energy and a lower linear speed. The solid cylinder will come in second in the race, followed by the tube. Figure 10.13 shows frames from a videotaped experiment that verify our conclusions.

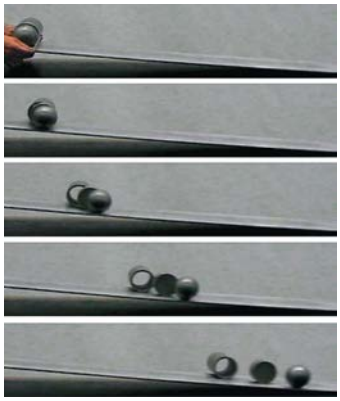

FIGURE 10.13
Race of a sphere, a solid cylinder, and a hollow cylinder of the same mass and radius down an inclined plane. The frames were shot at intervals of 0.5 s.

W. Bauer and G. D. Westfall

Self-Test Opportunity 10.2

Can you explain why the can of soda finishes the race in the position determined in Concept Check 10.4?

SOLVED PROBLEM 10.2 Ball Rolling through a Loop

A solid sphere is released from rest and rolls down an incline and then into a circular loop of radius R (see Figure 10.14). Assume that the radius of the sphere is much smaller than the radius of the loop.

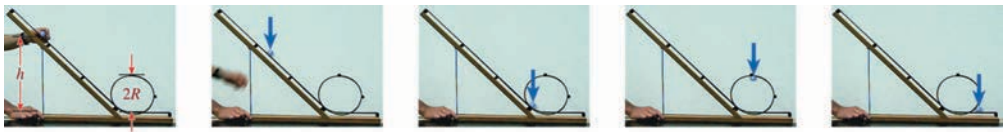

FIGURE 10.14 Sphere rolling down an incline and into a loop. The frames were shot at intervals of 0.25 s.

W. Bauer and G. D. Westfall

PROBLEM

What is the minimum height h from which the sphere has to be released so that it does not fall off the track when in the loop?

SOLUTION

THINK

When released from rest at a height h on the incline, the sphere has gravitational potential energy but no kinetic energy. As the sphere rolls down the incline and around the loop, gravitational potential energy is converted to kinetic energy. At the top of the loop, the sphere has dropped a distance $h - 2R$. The key to solving this problem is to realize that at the top of the loop, the centripetal acceleration has to be equal to or larger than the acceleration due to gravity. (When these accelerations are equal, "weightlessness" of the object occurs, as shown in Solved Problem 9.1. When the centripetal acceleration is greater, there must be a downward supporting force, which the track can supply. When the centripetal acceleration is less, there must be an upward supporting force, which the track cannot supply, so the sphere falls off the track.) What is unknown here is the speed v at the top of the loop. We can again employ energy

conservation considerations to calculate the minimum velocity required and then find the minimum starting height required for the sphere to remain on the track.

SKETCH

A sketch of the sphere rolling on the incline and loop is shown in Figure 10.15.

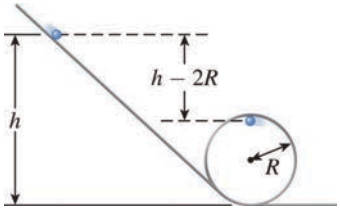

FIGURE 10.15
Sphere rolling on an incline and a loop.

RESEARCH

When the sphere is released, it has potential energy $U_0 = mgh$ and zero kinetic energy. At the top of the loop, the potential energy is $U = mg2R$, and the total kinetic energy is, according to equation 10.14, $K = (1 + c)\frac{1}{2}mv^2$, where $c_{\text{sphere}} = \frac{2}{5}$. Thus, conservation of total mechanical energy tells us that

$$E = K + U = (1 + c)\tfrac{1}{2}mv^2 + mg2R = K_0 + U_0 = m$$

At the top of the loop, the centripetal acceleration, a_c, has to be equal to or larger than the acceleration due to gravity, g:

$$g \leq a_c = \frac{v^2}{R}. \qquad \text{(ii)}$$

SIMPLIFY

We can solve equation (i) for v^2:

$$v^2 = \frac{2g(h - 2R)}{1 + c}.$$

If we then substitute this expression for v^2 into equation (ii), we find

$$g \leq \frac{2g(h - 2R)}{R(1 + c)}.$$

Multiplying both sides of this equation by the denominator of the fraction on the right side leads to

$$R(1 + c) \leq 2h - 4R.$$

Therefore, we have

$$h \geq \frac{5 + c}{2} R.$$

CALCULATE

This result is valid for any rolling object, with the constant c determined from the object's geometry. In this problem, we have a solid sphere, so $c = \frac{2}{5}$. Thus, the result is

$$h \geq \frac{5 + \frac{2}{5}}{2} R = \frac{27}{10} R.$$

ROUND

This problem situation was described in terms of variables rather than numerical values, so we can quote our result

exactly as

$$h \geq 2.7R.$$

DOUBLE-CHECK

If the sphere were not rolling but sliding without friction, we could equate the kinetic energy of the sphere at the top of the loop with the change in gravitational potential energy:

$$\tfrac{1}{2}mv^2 = mg(h - 2R).$$

We could then express the inequality between gravitational and centripetal acceleration given in equation (ii) as follows:

$$g \leq a_{\mathrm{c}} = \frac{v^2}{R} = \frac{2g(h - 2R)}{R}.$$

Solving this equation for h gives us

$$h \geq \frac{5}{2}R = 2.5R.$$

This required height for a sliding sphere is slightly lower than the height we found for a rolling sphere. We would expect that less energy, in the form of gravitational potential energy, would be required to keep the sphere on the track if it were not rolling because its kinetic energy would be entirely translational. Thus, our result for keeping a rolling sphere on the loop seems reasonable.

10.4 Torque

So far, in discussing forces, we have seen that a force can cause linear motion of an object, which can be described in terms of the motion of the center of mass of the object. However, we have not addressed one general question: Where are the force vectors acting on an extended object placed in a free-body diagram? A force can be exerted on an extended object at a point away from its center of mass, which can cause the object to rotate as well as move linearly.

Moment Arm

Consider the hand attempting to use a wrench to loosen a bolt in Figure 10.16. It is clear that it will be easiest to turn the bolt in Figure 10.16c, quite a bit harder in Figure 10.16b, and downright impossible in Figure 10.16a. This example shows that the magnitude of the force is not the only relevant quantity. The perpendicular distance from the line of action of the force to the axis of rotation, called the **moment arm,** is also important. In addition, the angle at which the force is applied, relative to the moment arm, matters as well. In parts (b) and (c) of Figure 10.16, this angle is 90°. (An angle of 270° would be just as effective, but then the force would act in the opposite direction.) An angle of 180° or 0° (Figure 10.16a) will not turn the bolt.

FIGURE 10.16 (a)–(c) Three ways to use a wrench to loosen a bolt. (d) The force $\vec{F}$ and moment arm r, with the angle θ between them.

W. Bauer and G. D. Westfall

These considerations are quantified by the concept of torque, τ. **Torque** (also called *moment*) is the vector product of the force $\vec{F}$ and the position vector $\vec{r}$:

$$\vec{\tau} = \vec{r} \times \vec{F}. \tag{10.16}$$

The position vector $\vec{r}$ is measured with the origin at the axis of rotation. The symbol $\times$ denotes the **vector product,** or *cross product*. (We introduced vector products in Chapter 1, which you may want to consult for a review.)

The SI unit of torque is N m, not to be confused with the unit of energy, which is the joule (J = N m)

$$[\tau] = [F] \cdot [r] = \text{N m}.$$

In English units, torque is often expressed in foot-pounds (ft-lb).

The magnitude of the torque is the product of the magnitude of the force and the distance to the axis of rotation (the magnitude of the position vector, or the moment arm) times the sine of the angle between the force vector and the position vector (see Figure 10.17):

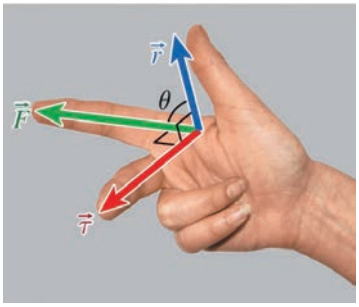

FIGURE 10.17
Right-hand rule for the direction of the torque for a given force and position vector.

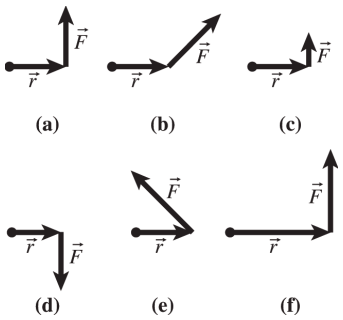
Mark Dierker/McGraw Hill

$$\tau = rF \sin\theta. \tag{10.17}$$

Angular quantities can also be vectors, called *axial vectors*. (An axial vector is any vector that points along the rotation axis.) Torque is an example of an axial vector, and its magnitude is given by equation 10.17. The direction of the torque is given by a right-hand rule (Figure 10.17). Note that right-hand rules apply to all vector products! The torque points in a direction perpendicular to the plane spanned by the force and position vectors. Thus, if the position vector points along the thumb and the force vector points along the index finger, then the direction of the axial torque vector is the direction of the middle finger, as shown in Figure 10.17. Note that the torque vector is perpendicular to both the force vector and the position vector.

Concept Check 10.5

Choose the combination of position vector, $\vec{r}$, and force vector, $\vec{F}$, that produces the torque of highest magnitude around the point indicated by the black dot.



With the mathematical definition of the torque, its magnitude, and its relation to the force vector, the position vector, and their relative angle, we can understand why the approach shown in part (c) of Figure 10.16 yields maximum torque for a given magnitude of the force, whereas that in part (a) yields zero torque. We see that the magnitude of the torque is the decisive factor in determining how easy or hard it is to loosen (or tighten) a bolt.

Torques around any fixed axis of rotation can be clockwise or counterclockwise. As indicated by the force vector in Figure 10.16d, the torque generated by the hand pulling on the wrench would be counterclockwise. The **net torque** is defined as the difference between the sum of all clockwise torques and the sum of all counterclockwise torques:

$$\tau_{\text{net}} = \sum_{i} \tau_{\text{counterclockwise},i} - \sum_{j} \tau_{\text{clockwise},j}$$

10.5 Newton's Second Law for Rotation

In Section 10.1, we noted that moment of inertia I is the rotational equivalent of mass. From Chapter 4, we know that the product of the mass and the linear acceleration is the net force acting on the object, as expressed by Newton's Second Law, $F_{\text{net}} = ma$. What is the equivalent of Newton's Second Law for rotational motion?

Let's start with a point particle of mass M moving in a circle around an axis at a distance R from the axis. If we multiply the moment of inertia for rotation about an axis parallel to the center of mass by the angular acceleration, we obtain

$$I\alpha = \left(R^2M\right)\alpha = RM(R\alpha) = RMa = RF_{\text{net}}.$$

Page 307

To obtain this result, we first used equation 10.11 with $c = 1$, then the relationship between angular and linear acceleration for motion on a circle, and then Newton's Second Law. Thus, the product of the moment of inertia and the angular acceleration is proportional to the product of a distance quantity and a force quantity. In Section 10.4, we saw that this product is a torque, τ. Thus, we can write the following form of Newton's Second Law for rotational motion:

$$\tau = I\alpha. \qquad \textbf{(10.18)}$$

Combining equations 10.16 and 10.18 gives us

$$\vec{\tau} = \vec{r} \times \vec{F}_{\text{net}} = I\vec{\alpha}. \qquad \textbf{(10.19)}$$

This equation for rotational motion is analogous to Newton's Second Law, $\vec{F} = m\vec{a}$, for linear motion. Figure 10.18 shows the relationship between force, position, torque, and angular acceleration for a point particle moving around an axis of rotation. Note that, strictly speaking, equation 10.19 holds only for a point particle in circular orbit. It seems plausible that this equation holds for a moment of inertia for an extended object in general, but we have not proven it. Later in this chapter, we will come back to this equation.

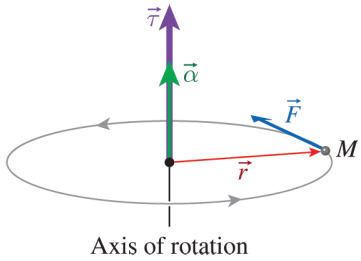


FIGURE 10.18 A force exerted on a point particle creates a torque.

Newton's First Law stipulates that in the absence of a net force, an object experiences no acceleration and thus no change in velocity. The equivalent of Newton's First Law for rotational motion is that an object experiencing no net torque has no angular acceleration and thus no change in angular velocity. In particular, this means that for objects to remain stationary, the net torque on them has to be zero. We will return to this statement in Chapter 11, where we investigate static equilibrium.

Now, however, we can use the rotational form of Newton's Second Law (equation 10.19) to solve interesting problems of rotational motion, such as the following one.

EXAMPLE 10.3 Toilet Paper

This may have happened to you: You are trying to put a new roll of toilet paper into its holder. However, you drop the roll, managing to hold onto just the first sheet. On its way to the floor, the toilet paper roll unwinds, as Figure 10.19a shows.

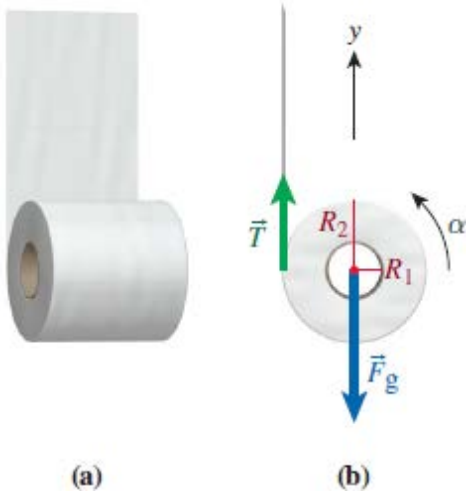

FIGURE 10.19 (a) Unrolling toilet paper. (b) Free-body diagram of the roll of toilet paper.

PROBLEM

How long does it take the roll of toilet paper to hit the floor, if it was released from a height of 0.73 m? The roll has an inner radius $R_1 = 2.7$ cm, an outer radius $R_2 = 6.1$ cm, and a mass of 274 g.

SOLUTION

For the falling roll of toilet paper, the acceleration is $a_y = -g$, and in Chapter 2, we saw that for free fall from rest, the position as a function of time is given in general as $y = y_0 + v_0 t - \frac{1}{2}gt^2$. In this case, the initial velocity is zero; therefore, $y = y_0 - \frac{1}{2}gt^2$. If we put the origin at floor level, then we have to find the time at which $y = 0$. This implies $y_0 = \frac{1}{2}gt^2$ for the time it takes the roll to hit the floor.

Therefore, the time it would take for the roll in free fall to hit the floor is

$$t_{\text{free}} = \sqrt{\frac{2y_0}{g}} = \sqrt{\frac{2(0.73\ \text{m})}{9.18\ \text{m/s}^2}} = 0.386\ \text{s}. \qquad \text{(i)}$$

However, since you hold onto the first sheet and the toilet paper unwinds on the way down, the roll of toilet paper is rolling without slipping (in the sense in which this was defined earlier). Therefore, the acceleration will be different from the free-fall case. Once we know the value of this acceleration, we can use a formula relating the initial height and fall time that is similar to equation (i).

How do we calculate the acceleration that the toilet paper experiences? Again, we start with a free-body diagram. Figure 10.19b shows the toilet paper roll in side view and indicates the force of gravity, $\overrightarrow{F}_{\text{g}} = mg\big(-\hat{y}\big)$, and the tension from the sheet that is held by the hand, $\overrightarrow{T} = T\hat{y}$. Newton's Second Law then allows us to relate the net force acting on the toilet paper to the acceleration of the roll:

$$T - mg = ma_y. \qquad \text{(ii)}$$

The tension and the acceleration are both unknown, so we need to find a second equation relating these quantities. This second equation can be obtained from the rotational motion of the roll, for which the net torque is the product of the moment of inertia and the angular acceleration: $\tau = I\alpha$. The moment of inertia of the roll of toilet paper is that of a hollow cylinder, $I = \frac{1}{2}m\big(R_1^2 + R_2^2\big)$, which is equation 10.9.

We can again relate the linear and angular accelerations via $a_y = R_2\alpha$, where R_2 is the outer radius of the roll of toilet paper. We need to specify which direction is positive for the angular acceleration—otherwise, we could get the sign wrong and thus obtain a false result. To be consistent with the choice of up as the positive y-direction, we need to select counterclockwise rotation as the positive angular direction, as indicated in Figure 10.19b.

For the torque about the axis of symmetry of the roll of toilet paper, we have $\tau = -R_2T$, with the sign convention for positive angular acceleration that we just established. The force of gravity does not contribute to the torque about the axis of symmetry, because its moment arm has a length of zero. Newton's Second Law for rotational motion then leads to

$$\begin{aligned} \tau &= I\alpha \\ -R_2T &= \left[\tfrac{1}{2}m\left(R_1^2 + R_2^2\right)\right]\frac{a_y}{R_2} \\ -T &= \tfrac{1}{2}m\left(1 + \frac{R_1^2}{R_2^2}\right)a_y. \end{aligned} \qquad \text{(iii)}$$

Equations (ii) and (iii) form a set of two equations for the two unknown quantities, T and a_y. Adding them results in

$$-mg = \frac{1}{2}m\left(1 + \tfrac{R_1^2}{R_2^2}\right)a_y + ma_y.$$

The mass of the roll of toilet paper cancels out, and we find for the acceleration

$$a_y = -\frac{g}{\dfrac{3}{2} + \dfrac{R_1^2}{2R_2^2}}.$$

Using the given values for the inner radius, $R_1 = 2.7\ \text{cm}$, and the outer radius, $R_2 = 6.1\ \text{cm}$, we find the value of the

acceleration:

$$a_y = -\frac{9.81\ \text{m/s}^2}{\frac{3}{2} + \frac{(2.7\ \text{cm})^2}{2(6.1\ \text{cm})^2}} = -6.14\ \text{m/s}^2.$$

Inserting this value for the acceleration into a formula for the fall time that is analogous to equation (i) gives our answer

$$t = \sqrt{\frac{2y_0}{-a_y}} = \sqrt{\frac{2(0.73\ \text{m})}{6.14\ \text{m/s}^2}} = 0.488\ \text{s}.$$

This is approximately 0.1 s longer than the time for the free-falling roll of toilet paper released from the same height.

DISCUSSION

Note that we assumed that the outer radius of the roll of toilet paper did not change as the paper unwound. For the short distance of less than 1 m, this is justified. However, if we wanted to calculate how long it took for the toilet paper to unwind over a distance of, say, 10 m, we would need to take the change in outer radius into account. Of course, then we would also need to take into account the effect of air resistance!

As an extension of Example 10.3, we can consider a yo-yo. A yo-yo consists of two solid disks of radius R_2, with a thin smaller disk of radius R_1 mounted between them, and a string wound around the smaller disk (see Figure 10.20). For the purpose of this analysis, we can consider the moment of inertia of the yo-yo to be that of a solid disk with radius R_2: $I = \frac{1}{2}mR_2^2$. The free-body diagrams of Figure 10.19b and Figure 10.20b are almost identical, except for one detail: For the yo-yo, the string tension acts on the surface at the inner radius R_1, as opposed to the outer radius R_2, as was the case for the roll of toilet paper. This implies that the angular and linear accelerations for the yo-yo are proportional to each other, with proportionality constant R_1 (instead of R_2 as for

the roll). Thus, the torque for the yo-yo rolling without slipping along the string is

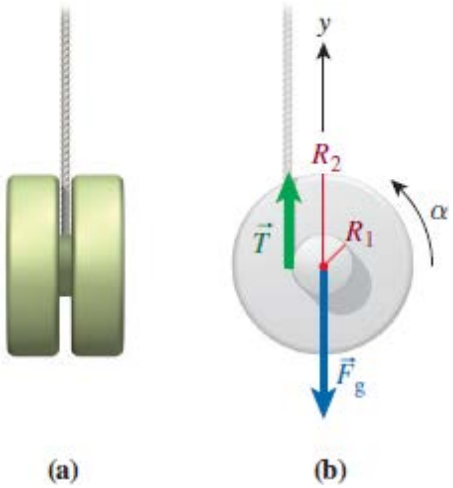

FIGURE 10.20 (a) Yo-yo. (b) Free-body diagram of the yo-yo.

$$\tau = I\alpha \Rightarrow -TR_1 = \left(\tfrac{1}{2}\mathrm{m}R_2^2\right)\frac{a_y}{R_1}$$

$$-T = \tfrac{1}{2}m\frac{R_2^2}{R_1^2}a_y.$$

It is instructive to compare this equation to $-T = \frac{1}{2}m\left(1 + R_1^2/R_2^2\right)a_y$, which we derived in Example 10.3 for the roll of toilet paper. They look very similar, but the ratio of the radii is different. On the other hand, the equation derived from Newton's Second Law (for translation) is the same in both cases:

$$T - mg = ma_y.$$

Adding this equation and the equation for the torque of the yo-yo yields the acceleration of the yo-yo:

$$-mg = ma_y + \tfrac{1}{2} m \frac{R_2^2}{R_1^2} a_y \Rightarrow$$

$$a_y = -\frac{g}{1 + \frac{1}{2}\dfrac{R_2^2}{R_1^2}} = -\frac{2R_1^2}{2R_1^2 + R_2^2} g.$$

For example, if $R_2 = 5R_1$, the acceleration of the yo-yo is

$$a_y = \frac{-g}{1 + \frac{1}{2}(25)} = \frac{-g}{13.5} = -0.727 \text{ m/s}^2.$$

Atwood Machine

Chapter 4 introduced an Atwood machine, which consists of two weights with masses m_1 and m_2 connected by a string or rope, which is guided over a pulley. The machines we analyzed in Chapter 4 were subject to the condition that the rope glides without friction over the pulley so that the pulley does not rotate (or, equivalently, that the pulley is massless). In such cases, the common acceleration of the two masses is $a = g(m_1 - m_2)/(m_1 + m_2)$. With the concepts of rotational dynamics, we can take another look at the Atwood machine and consider the case where friction occurs between the rope and the pulley, causing the rope to turn the pulley without slipping.

In Chapter 4, we saw that the magnitude of the tension, T, is the same everywhere in a string. However, now friction forces are involved to keep the string attached to the pulley, and we cannot assume that the tension is constant. Instead, the string tension is separately determined in each segment of the string from which one of the two masses hang. Thus, there are two different string tensions, T_1 and T_2, in the free-body diagrams for the two masses (as shown in Figure 10.21b). Just as in Chapter 4, applying Newton's Second Law individually to each free-body diagram leads to

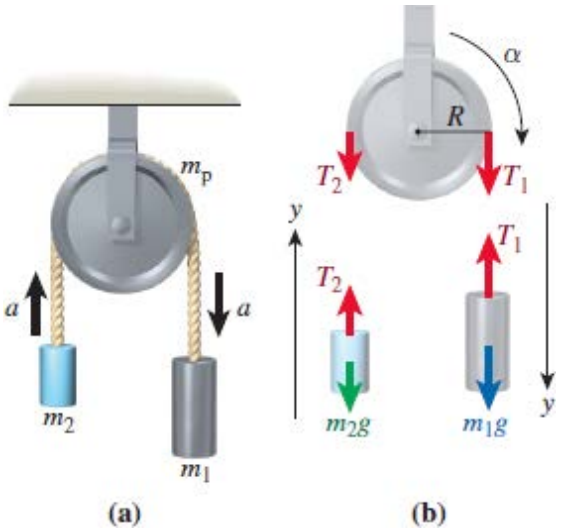

FIGURE 10.21 Atwood machine: (a) physical setup; (b) free-body diagrams.

$$-T_1 + m_1 g = m_1 a \qquad \textbf{(10.20)}$$

$$T_2 - m_2 g = m_2 a. \qquad \textbf{(10.21)}$$

Here again we used the (arbitrary) sign convention that a positive acceleration ($a > 0$) is one for which m_1 moves downward and m_2 upward. This convention is indicated in the free-body diagrams by the direction of the positive y-axis.

Figure 10.21b also shows a free-body diagram for the pulley, but it includes only the forces that can cause a torque: the two string tensions, T_1 and T_2. The downward force of gravity and the upward force of the support structure on the pulley are not shown. The pulley does not have translational motion, so all forces acting on the pulley add up to zero. However, a net torque does act on the pulley. According to equation 10.17, the magnitude of the torque due to the string tensions is given by

$$\tau = \tau_1 - \tau_2 = RT_1 \sin 90^\circ - RT_2 \sin 90^\circ = R(T_1 - T_2). \textbf{(10.}$$

These two torques have opposite signs, because one is acting clockwise and the other counterclockwise. According to equation 10.18, the net torque is related to the moment of inertia of the pulley and its angular acceleration by $\tau = I\alpha$. The moment of inertia of the pulley (mass of m_p) is that of a disk: $I = \frac{1}{2} m_\mathrm{p} R^2$. Since the rope moves across the pulley without slipping, the acceleration of the rope (and masses m_1 and m_2) is related to the angular acceleration via $\alpha = a/R$, just like the correspondence established in Chapter 9 between linear and angular acceleration for a point particle moving on the circumference of a circle.

Inserting the expressions for the moment of inertia and the angular acceleration results in $\tau = I\alpha = \left(\frac{1}{2}m_{\mathrm{p}}R^2\right)(a/R)$. Substituting this expression for the torque into equation 10.22, we find

$$\begin{gathered} R(T_1 - T_2) = \tau = \left(\tfrac{1}{2}m_{\mathrm{p}}R^2\right)\left(\frac{a}{R}\right) \Rightarrow \\ T_1 - T_2 = \tfrac{1}{2}m_{\mathrm{p}}a. \end{gathered} \qquad \textbf{(10.23)}$$

Equations 10.20, 10.21, and 10.23 form a set of three equations for three unknown quantities: the two values of the string tension, T_1 and T_2, and the acceleration, a. The easiest way to solve this system for the acceleration is to add the equations. We then find

$$\begin{gathered} m_1 g - m_2 g = \left(m_1 + m_2 + \tfrac{1}{2}m_{\mathrm{p}}\right)a \Rightarrow \\ a = \frac{m_1 - m_2}{m_1 + m_2 + \frac{1}{2}m_{\mathrm{p}}}g. \end{gathered} \qquad \textbf{(10.24)}$$

Note that equation 10.24 matches the equation for the case of a massless pulley (or the case in which the rope slides over the pulley without friction), except for the additional term of $\frac{1}{2}m_{\mathrm{p}}$ in the denominator, which represents the contribution of the pulley to the overall inertia of the system. The factor $\frac{1}{2}$ reflects the shape of the pulley, a disk, because $c = \frac{1}{2}$ for a disk in the relationship between moment of inertia, mass, and radius (equation 10.11).

Thus, we have answered the question of what happens when a force is exerted on an extended object some distance away from its center of mass: The force produces a torque as well as linear motion. This torque leads to rotation, which we left out of our original considerations of the result of exerting a force on an object because we assumed that all forces acted on the center of mass of the object.

SOLVED PROBLEM 10.3 Falling Horizontal Rod

A thin rod of length $L = 2.50\,\text{m}$ and mass $m = 3.50\,\text{kg}$ is suspended horizontally by a pair of vertical strings attached to the ends (Figure 10.22). The string supporting end B is then cut.

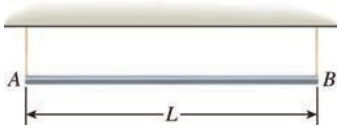

FIGURE 10.22 A thin rod supported in a horizontal position by a vertical string at each end.

PROBLEM

What is the linear acceleration of end B of the rod just after the string is cut?

SOLUTION

THINK

Before the string is cut, the rod is at rest. When the string supporting end B is cut, a net torque acts on the rod, with a pivot point at end A. This torque is due to the force of gravity acting on the rod. We can consider the mass of the rod to be concentrated at its center of mass, which is located at $L/2$. The initial torque is then equal to the weight of the rod times the moment arm, which is $L/2$. The resulting initial angular acceleration can be related to the linear acceleration of end B of the rod.

SKETCH

Figure 10.23 is a sketch of the rod after the string is cut.

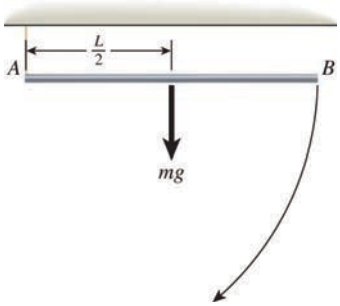

FIGURE 10.23
The thin rod just after the string supporting end *B* is cut.

RESEARCH

When the string supporting end B is cut, the torque, τ, on the rod is due to the force of gravity, F_g, acting on the rod times the moment arm, $r_\perp = L/2$:

$$\tau = r_\perp F_g = \left(\frac{L}{2}\right)(mg) = \frac{mgL}{2}. \qquad \text{(i)}$$

The angular acceleration, α, is given by

$$\tau = I\alpha, \qquad \text{(ii)}$$

where the moment of inertia, I, of the thin rod rotating around end A is given by

$$I = \tfrac{1}{3}mL^2. \qquad \text{(iii)}$$

The linear acceleration, a, of end B can be related to the angular acceleration through

$$a = L\alpha, \qquad \text{(iv)}$$

because end B of the rod is undergoing circular motion as the rod pivots around end A.

SIMPLIFY

We can combine equations (i) and (ii) to get

$$\tau = I\alpha = \frac{mgL}{2}. \qquad \text{(v)}$$

Substituting for I and a from equations (iii) and (iv) into equation (v) gives us

$$I\alpha = \left(\tfrac{1}{3}mL^2\right)\left(\frac{a}{L}\right) = \frac{mgL}{2}.$$

Dividing out common factors, we obtain

$$\frac{a}{3} = \frac{g}{2}$$

or

$$a = 1.5\,g.$$

CALCULATE

Inserting the numerical value for the acceleration of gravity gives us

$$a = 1.5\left(9.81\ \text{m/s}^2\right) = 14.715\ \text{m/s}^2.$$

ROUND

Expressing our result to three significant figures gives

$$a = 14.7 \text{ m/s}^2.$$

DOUBLE-CHECK

Perhaps this answer is somewhat surprising, because you may have assumed that the acceleration cannot exceed the free-fall acceleration, g. If both strings were cut at the same time, the acceleration of the entire rod would be $a = g$. Our result of an initial acceleration of end B of $a = 1.5g$ seems reasonable because the full force of gravity is acting on the rod and end A of the rod remains fixed. Therefore, the acceleration of the moving ends is not just that due to free fall—there is an additional acceleration due to the rotation of the rod.

10.6 Work Done by a Torque

In Chapter 5, we saw that the work W done by a force $\vec{F}$ is given by the integral

$$W = \int_{x_0}^{x} F_x(x')\,dx'.$$

We can now consider the work done by a torque $\vec{\tau}$.

Torque is the angular equivalent of force. The angular equivalent of the linear displacement, $\vec{dr}$, is the angular displacement, $\vec{d\theta}$. Since both the torque and the angular displacement are axial vectors and point in the direction of the axis of rotation, we can write their scalar product as $\vec{\tau} \bullet \vec{d\theta} = \tau\, d\theta$. Therefore, the work done by a torque is

$$W = \int_{\theta_0}^{0} \tau(\theta')\,d\theta'. \qquad \textbf{(10.25)}$$

For the special case where the torque is constant and thus does not depend on θ, the integral of equation 10.25 simply evaluates to

$$W = \tau(\theta - \theta_0). \qquad \textbf{(10.26)}$$

Chapter 5 also presented the first version of the work–kinetic energy theorem: $\Delta K \equiv K - K_0 = W$. The rotational equivalent of

this work–kinetic energy relationship can be written with the aid of equation 10.3 as follows:

$$\Delta K \equiv K - K_0 = \tfrac{1}{2} I\omega^2 - \tfrac{1}{2} I\omega_0^2 = W. \qquad \textbf{(10.27)}$$

For the case of a constant torque, we can use equation 10.26 and find the work–kinetic energy theorem for constant torque:

$$\tfrac{1}{2} I\omega^2 - \tfrac{1}{2} I\omega_0^2 = \tau(\theta - \theta_0). \qquad \textbf{(10.28)}$$

EXAMPLE 10.4 Tightening a Bolt

PROBLEM

What is the total work required to completely tighten the bolt shown in Figure 10.24? The total number of turns is 30.5, the diameter of the bolt is 0.860 cm, and the friction force between the nut and the bolt is a constant 14.5 N.

FIGURE 10.24
Tightening a bolt.

W. Bauer and G. D. Westfall

SOLUTION

Since the friction force is constant and the diameter of the bolt is constant, we can calculate directly the torque needed to turn the nut:

$$\tau = Fr = \tfrac{1}{2}Fd = \tfrac{1}{2}(14.5\text{ N})(0.860\text{ cm}) = 0.0623\text{ N m}.$$

In order to calculate the total work required to completely tighten the bolt, we need to figure out the total angle. Each turn corresponds to an angle of 2π rad. so the total angle in this case is $\Delta\theta = 30.5(2\pi) = 191.6$ rad.

The total work required is then obtained by making use of equation 10.26:

$$W = \tau\Delta\theta = (0.0623\text{ N m})(191.6) = 11.9\text{ J}.$$

As you can see, figuring out the work done is not very difficult with a constant torque. However, in many physical situations, the torque cannot be considered to be constant. The next example illustrates such a case.

EXAMPLE 10.5 Driving a Screw

The friction force between a drywall screw and wood is proportional to the contact area between the screw and the wood. Since the drywall screw has a constant diameter, this means that the torque required for turning the screw increases linearly with the depth to which the screw has penetrated into the wood.

PROBLEM

Suppose it takes 27.3 turns to screw a drywall screw completely into a block of wood (Figure 10.25). The torque needed to turn the screw increases linearly from zero at the beginning to a maximum of 12.4 N m at the end. What is the total work required to drive in the screw?

FIGURE 10.25
Driving a drywall screw into a block of wood.

W. Bauer and G. D. Westfall

SOLUTION

Clearly, the torque is a function of the angle in this situation and is not constant anymore. Thus, we have to use the integral of equation 10.25 to find our answer. First, let us calculate the total angle, θ_{total}, that the screw turns through: $\theta_{\text{total}} = 27.3(2\pi) = 171.5$ rad. Now we need to find an expression for $\tau(\theta)$. A linear increase with θ from zero to 12.4 N m means

$$\tau(\theta) = \theta \frac{\tau_{\max}}{\theta_{\text{total}}}.$$

Now we can evaluate the integral as follows:

$$W = \int_0^{\theta_{\text{total}}} \tau(\theta')\,d\theta' = \int_0^{\theta_{\text{total}}} \theta' \frac{\tau_{\max}}{\theta_{\text{total}}}\,d\theta' = \frac{\tau_{\max}}{\theta_{\text{total}}} \int_0^{\theta_{\text{total}}} \theta'\,d\theta' =$$

Inserting the numbers, we obtain

$$W = \frac{1}{2}\tau_{\max}\theta_{\text{total}} = \frac{1}{2}(12.4\ \text{N m})(171.5\ \text{rad}) = 1.06\ \text{kJ}.$$

Concept Check 10.6

If you want to reduce the torque required to drive in a screw, you can rub soap on the thread beforehand. Suppose the soap reduces the coefficient of friction between the screw and the wood by a factor of 2 and therefore reduces the required torque by a factor of 2. How much does it change the total work required to turn the screw into the wood?

a) It leaves the work the same.

b) It reduces the work by a factor of 2.

c) It reduces the work by a factor of 4.

Concept Check 10.7

If you get tired before you finish driving in the screw and you manage to screw it in only halfway, how does this change the total work you have done, relative to the work done in driving the screw all the way in?

a) It leaves the work the same.

b) It reduces the work by a factor of 2.

c) It reduces the work by a factor of 4.

SOLVED PROBLEM 10.4 Atwood Machine

PROBLEM

Two weights with masses $m_1 = 3.00$ kg and $m_2 = 1.40$ kg are connected by a very light rope that runs without sliding over a pulley (solid disk) of mass $m_p = 2.30$ kg. The two masses initially hang at the same height and are at rest. Once released, the heavier mass, m_1, descends and lifts up the lighter mass, m_2. What speed will m_2 have at height $h = 0.16$ m?

SOLUTION

THINK

We could try to calculate the acceleration of the two masses and then use kinematical equations to relate this acceleration to the vertical displacement. However, we can also use energy considerations, which will lead to a fairly direct solution. Initially, the two hanging masses and the pulley are at rest, so the total kinetic energy is zero. We can choose a coordinate system such that the initial potential energy is zero, and thus the total energy is zero. As one of the masses is lifted, it gains gravitational potential energy, and the other mass loses potential energy. Both masses gain translational kinetic energy, and the pulley gains rotational kinetic energy. Since the kinetic energy is proportional to the square of the speed, we can then use energy conservation to solve for the speed.

SKETCH

Figure 10.26a shows the initial state of the Atwood machine with both hanging masses at the same height. We decide to set that height as the origin of the vertical axis, thus ensuring that the initial potential energy, and therefore the total initial energy, is zero. Figure 10.26b shows the Atwood machine with the masses displaced by h.

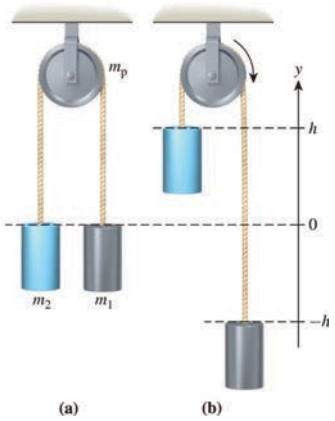

FIGURE 10.26
One more Atwood machine: (a) initial positions; (b) positions after the weights move a distance *h*.

RESEARCH

The gain in gravitational potential energy for m_2 is $U_2 = m_2gh$. At the same time, m_1 is lowered the same distance, so its potential energy is $U_1 = -m_1gh$. The kinetic energy of m_1 is $K_1 = \frac{1}{2}m_1v^2$, and the kinetic energy of m_2 is $K_2 = \frac{1}{2}m_2v^2$. Note that the same speed, v, is used in the energy expressions for the two masses. This equality is assured, because a rope connects them. (We assume that the rope does not stretch.)

What about the rotational kinetic energy of the pulley? The pulley is a solid disk with a moment of inertia given by $I = \frac{1}{2}m_pR^2$ and a rotational kinetic energy given by $K_r = \frac{1}{2}I\omega^2$. Since the rope runs over the pulley without slipping and also moves with the same speed as the two masses, points on the surface of the pulley also have to move with that same linear speed, v. Just as for a rolling solid disk, the linear speed is related to the angular speed via $\omega R = v$. Thus, the rotational kinetic energy of the pulley is

$$K_r = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}m_pR^2\right)\omega^2 = \tfrac{1}{4}m_pR^2\omega^2 = \tfrac{1}{4}m_pv^2.$$

Now we can express the total energy as the sum of the potential and translational and rotational kinetic energies. This overall sum has to equal zero, because that was the initial value of the total energy and energy conservation applies:

$$\begin{aligned} 0 &= U_1 + U_2 + K_1 + K_2 + K_\mathrm{r} \\ &= -m_1 g h + m_2 g h + \tfrac{1}{2} m_1 v^2 + \tfrac{1}{2} m_2 v^2 + \tfrac{1}{4} m_\mathrm{p} v^2. \end{aligned}$$

SIMPLIFY

We can rearrange the preceding equation to isolate the speed, v:

$$\begin{aligned} (m_1 - m_2) g h = \left(\tfrac{1}{2} m_1 + \tfrac{1}{2} m_2 + \tfrac{1}{4} m_\mathrm{p}\right) v^2 \Rightarrow \\ v = \sqrt{\frac{2(m_1 - m_2) g h}{m_1 + m_2 + \frac{1}{2} m_\mathrm{p}}}. \end{aligned} \qquad \text{(i)}$$

CALCULATE

Now we insert the numbers:

$$v = \sqrt{\frac{2(3.00\ \mathrm{kg} - 1.40\ \mathrm{kg})\left(9.81\ \mathrm{m/s^2}\right)(0.16\ \mathrm{m})}{3.00\ \mathrm{kg} + 1.40\ \mathrm{kg} + \frac{1}{2}(2.30\ \mathrm{kg})}} = 0.95$$

ROUND

The displacement h was given with the least precision, to two digits, so we round our result to

$$v = 0.95\ \mathrm{m/s}.$$

DOUBLE-CHECK

The acceleration of the masses is given by equation 10.24, which we developed in Section 10.5 in discussing the Atwood machine:

$$a = \frac{m_1 - m_2}{m_1 + m_2 + \frac{1}{2}m_p} g. \qquad \text{(ii)}$$

Chapter 2 presented kinematical equations for one-dimensional linear motion. One of these, which relates the initial and final speeds, the displacement, and the acceleration, now comes in handy:

$$v^2 = v_0^2 + 2a(y - y_0).$$

Here $v_0 = 0$ and $y - y_0 = h$. Then, inserting the expression for a from equation (ii) leads to our result

$$v^2 = 2ah = 2\frac{m_1 - m_2}{m_1 + m_2 + \frac{1}{2}m_p} gh \Rightarrow v = \sqrt{\frac{2(m_1 - m}{m_1 + m_2 +}}$$

This equation for the speed is identical to equation (i), which we obtained using energy considerations. The effort it took to develop the equation for the acceleration makes it clear that the energy method is the quicker way to proceed.

Concept Check 10.8

We used the law of energy conservation in Solved Problem 10.4. But the friction force, a nonconservative force, prevents the rope from slipping over the pulley and causes the pulley to rotate. Which of the following statements justifies our use of energy conservation in this situation?

a) Because the friction force acts on both sides of the pulley, it cancels out.

b) Because the friction force points in the same direction as the tension in the rope, it does not contribute to the work done.

c) Because the friction force does not cause a displacement of the rope relative to the pulley, it does not do any work and therefore does not change the total mechanical energy.

d) Since the pulley rotates freely, the friction force does not act on the pulley.

10.7 Angular Momentum

Although we have discussed the rotational equivalents of mass (moment of inertia), velocity (angular velocity), acceleration (angular acceleration), and force (torque), we have not yet encountered the rotational analogue to linear momentum. Since linear momentum is the product of an object's velocity and its mass, by analogy, the angular momentum should be the product of angular velocity and moment of inertia. In this section, we will find that this relationship is indeed true for an extended object with a fixed moment of inertia. However, to reach that conclusion, we need to start from a definition of angular momentum for a point particle and proceed from there.

Point Particle

The **angular momentum,** $\vec{L}$, of a point particle is the vector product of its position and momentum vectors:

$$\vec{L} = \vec{r} \times \vec{p}. \qquad \textbf{(10.29)}$$

Because the angular momentum is defined as $\vec{L} = \vec{r} \times \vec{p}$ and the torque is defined as $\vec{\tau} = \vec{r} \times \vec{F}$, statements can be made about angular momentum that are similar to those made about torque in Section 10.4. For example, the magnitude of the angular momentum is given by

$$L = rp \sin \theta, \qquad \textbf{(10.30)}$$

where θ is the angle between the position and momentum vectors. Also, just like the direction of the torque vector, the direction of the angular momentum vector is given by a right-hand rule. Let the thumb of the right hand point along the position vector, $\vec{r}$, of a point particle and the index finger point along the momentum vector, $\vec{p}$, then the middle finger will indicate the direction of the angular momentum vector $\vec{L}$ (Figure 10.27). As an example, the angular momentum vector of a point particle located in the *xy*-plane is illustrated in Figure 10.28.

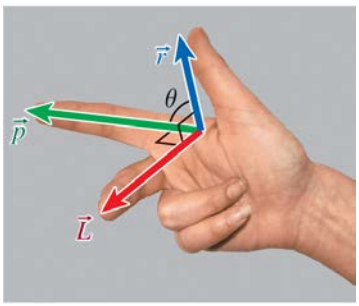

FIGURE 10.27 Right-hand rule for the direction of the angular momentum vector: The thumb is aligned with the position vector and the index finger with the momentum vector; then the angular momentum vector points along the middle finger.

Mark Dierker/McGraw Hill

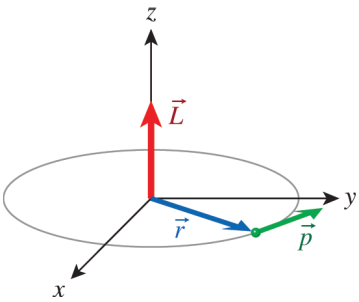

FIGURE 10.28 The angular momentum of a point particle.

Given the definition of the angular momentum in equation 10.29, we can take the time derivative:

$$\frac{d}{dt}\vec{L} = \frac{d}{dt}\left(\vec{r} \times \vec{p}\right) = \left[\left(\frac{d}{dt}\vec{r}\right) \times \vec{p}\right] + \left(\vec{r} \times \frac{d}{dt}\vec{p}\right) = \left(\vec{v} \times$$

To take the derivative of the vector product, we apply the product rule of calculus. The term $\vec{v} \times \vec{p}$ is always zero, because $\vec{v} \parallel \vec{p}$. Also, from equation 10.16, we know that $\vec{r} \times \vec{F} = \vec{\tau}$. Thus, we obtain for the time derivative of the angular momentum vector:

$$\frac{d}{dt}\vec{L} = \vec{\tau}. \qquad \textbf{(10.31)}$$

The time derivative of the angular momentum vector for a point particle is the torque vector acting on that point particle. This result is again analogous to the linear motion case, where the time derivative of the linear momentum vector is equal to the force vector.

The vector product allows us to revisit the relationship between the linear velocity vector, the coordinate vector, and the angular velocity vector, which was introduced in Chapter 9. (Again, we consider the special case illustrated in Figure 10.28, where the position and momentum vectors are located in a two-dimensional plane.) For circular motion, the magnitudes of those vectors are related via $\omega = v/r$, and the direction of $\vec{\omega}$ is given by a right-hand rule. Using the definition of the vector product, we can write $\vec{\omega}$ as

$$\vec{\omega} = \frac{\vec{r} \times \vec{v}}{\vec{r}}. \qquad \textbf{(10.32)}$$

Comparing equations 10.29 and 10.32 reveals that the angular momentum and angular velocity vectors for the point particle are parallel, with

$$\overrightarrow{L} = \overrightarrow{\omega} \cdot \left(mr^2\right). \qquad \textbf{(10.33)}$$

The quantity mr^2 is the moment of inertia of a point particle orbiting the axis of rotation at a distance r.

System of Particles

It is straightforward to generalize the concept of angular momentum to a system of n point particles. The total angular momentum of the system of particles is simply the sum of the angular momenta of the individual particles:

$$\vec{L} = \sum_{i=1}^{n} \vec{L}_i = \sum_{i=1}^{n} \vec{r}_i \times \vec{p}_i = \sum_{i=1}^{n} m_i \vec{r}_i \times \vec{v}_i. \quad \textbf{(10.34)}$$

Again, we take the time derivative of this sum of angular momenta in order to obtain the relationship between the total angular momentum of this system and the torque:

$$\begin{aligned} \frac{d}{dt}\vec{L} &= \frac{d}{dt}\left(\sum_{i=1}^{n} \vec{L}_i\right) = \frac{d}{dt}\left(\sum_{i=1}^{n} \vec{r}_i \times \vec{p}_i\right) = \sum_{i=1}^{n} \frac{d}{dt}\left(\vec{r}_i \times \vec{p}_i \right. \\ &= \sum_{i=1}^{n} \underbrace{\underbrace{\left(\frac{d}{dt}\vec{r}_i\right)}_{\text{Equals } \vec{v}_i} \times \vec{p}_i}_{\text{Equals zero, because } \vec{v}_i \| \vec{p}_i} + \vec{r}_i \times \underbrace{\left(\frac{d}{dt}\vec{p}_i\right)}_{\vec{F}_i} = \sum_{i=1}^{n} \vec{r}_i \times \vec{F}_i = \sum_{i=} \end{aligned}$$

As expected, we find that the time derivative of the total angular momentum for a system of particles is given by the total net external torque acting on the system. It is important to keep in mind that this is the net *external* torque due to the *external* forces, $\vec{F}_i$.

Self-Test Opportunity 10.3

Can you show that internal torques (those due to internal forces between particles in a system) do not contribute to the total net torque? (*Hint:* Use Newton's Third Law, $\overrightarrow{F}_{i\to j} = -\overrightarrow{F}_{j\to i}$.

Rigid Objects

A rigid object will rotate about a fixed symmetry axis with an angular velocity $\vec{\omega}\,\omega$ that is the same for every part of the object. In this case, the angular momentum is proportional to the angular velocity, and the proportionality constant is the moment of inertia:

$$\vec{L} = I\vec{\omega}. \tag{10.35}$$

DERIVATION 10.4 Angular Momentum of a Rigid Object

Representing the rigid object by a collection of point particles allows us to use the results of the preceding subsection as a starting point. In order for point particles to represent the rigid object, their relative distances from one another must remain constant (rigid). Then all of these point particles rotate with a constant angular velocity, $\vec{\omega}$, about the common rotation axis.

From equation 10.34, we obtain

$$\vec{L} = \sum_{i=1}^{n} \vec{L}_i = \sum_{i=1}^{n} m_i \vec{r}_i \times \vec{v}_i = \sum_{i=1}^{n} m_i r_{i\perp}^2 \vec{\omega}.$$

Page 316

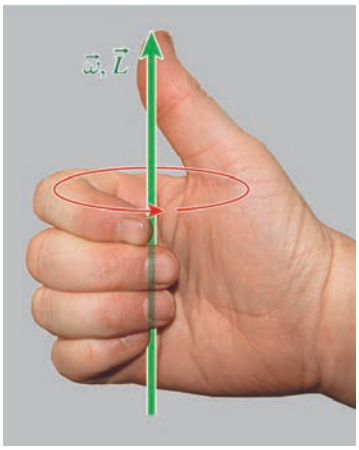
In the last step, we have used the relationship between the angular velocity and the vector product of the position and linear velocity vectors for point particles, equation 10.32, where $r_{i\perp}$ is the orbital radius of the point particle i. Note that the angular velocity vector is the same for all point particles in this rigid object. Therefore, we can move it out of the sum as a common factor:

$$\vec{L} = \vec{\omega} \sum_{i=1}^{n} m_i r_{i\perp}^2.$$

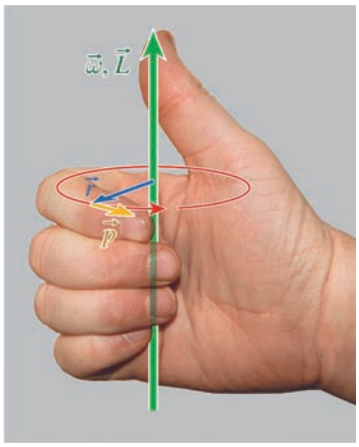
We can identify this sum as the moment of inertia of a collection of point particles; see equation 10.4. Thus, we finally have our result:

$$\vec{L} = I\vec{\omega}.$$

For rigid objects rotating about a symmetry axis, just as for point particles, the direction of the angular momentum vector is the same as the direction of the angular velocity vector. Figure 10.29 shows the right-hand rule used to determine the direction of the angular momentum vector (arrow along the direction of the thumb) as a function of the sense of rotation (direction of the fingers). What happens if the axis of rotation is not a symmetry axis of the rigid object? In this case, the angular momentum vector does not necessarily point in the direction of the angular velocity vector, and the math becomes quite a bit more complicated, beyond the scope of this book. A common example of this situation occurs when a car's wheel goes out of alignment (for example, after hitting a curb with the rim). The wheel will start to wobble, which can be quite dangerous, because it puts a lot of mechanical stress on both wheel and axle.



(a)



(b)

FIGURE 10.29 (a) Right-hand rule for the direction of the angular momentum (along the thumb) as a function of the direction of rotation (along the fingers). (b) The momentum and position vectors of a point particle in circular motion.

EXAMPLE 10.6 Golf Ball

PROBLEM

What is the magnitude of the angular momentum of a golf ball $\left(m = 4.59 \cdot 10^{-2}\ \text{kg}, R = 2.13 \cdot 10^{-2}\ \text{m}\right)$ spinning at 4250 rpm (revolutions per minute) after a good hit with a driver?

SOLUTION

First, we need to find the angular velocity of the golf ball, which involves use of the concepts introduced in Chapter 9:

$$\omega = 2\pi f = 2\pi\left(4250\ \text{min}^{-1}\right) = 2\pi\left(4250/60\ \text{s}^{-1}\right) = 445.1$$

The moment of inertia of the golf ball is

$$I = \frac{2}{5}mR^2 = 0.4\left(4.59 \cdot 10^{-2}\ \text{kg}\right)\left(2.13 \cdot 10^{-2}\ \text{m}\right)^2 = 8.3$$

The magnitude of the angular momentum of the golf ball is then simply the product of these two numbers:

$$L = \left(8.33 \cdot 10^{-6}\ \text{kg m}^2\right)\left(445.1\ \text{s}^{-1}\right) = 3.71 \cdot 10^{-3}\ \text{kg m}^2\text{s}$$

Using equation 10.35 for the angular momentum of a rigid object, we can show that the relationship between the rate of change of the angular momentum and the torque is still valid. Taking the time derivative of equation 10.35, and assuming a rigid body whose moment of inertia is constant in time, we obtain

$$\frac{d}{dt}\vec{L} = \frac{d}{dt}\left(I\vec{\omega}\right) = I\frac{d}{dt}\vec{\omega} = I\vec{\alpha} = \vec{\tau}_{\text{net}}. \qquad \textbf{(10.36)}$$

Note the addition of the index “net” to the symbol for torque, indicating that this equation also holds if different torques are present. Earlier, equation 10.19 was said to be true only for a point particle. However, equation 10.36 clearly shows that equation 10.19 holds for any object with a fixed (constant in time) moment of inertia.

The time derivative of the angular momentum is equal to the torque, just as the time derivative of the linear momentum is equal to the force. Equation 10.31 is another formulation of Newton’s Second Law for rotation and is more general than equation 10.19, because it also encompasses the case of a moment of inertia that is not constant in time.

Conservation of Angular Momentum

If the net external torque on a system is zero, then according to equation 10.36, the time derivative of the angular momentum is also zero. However, if the time derivative of a quantity is zero, then the quantity is constant in time. Therefore, we can write the law of **conservation of angular momentum:**

$$\text{If } \vec{\tau}_{\text{net}} = 0 \Rightarrow \vec{L} = \text{constant} \Rightarrow \vec{L}(t) = \vec{L}(t_0) \equiv \vec{L}_0. \quad \textbf{(10.37)}$$

This is the third major conservation law that we have encountered—the first two applied to mechanical energy (Chapter 6) and linear momentum (Chapter 7). Like the other conservation laws, this one can be used to solve problems that would otherwise be very hard to attack.

If there are several objects present in a system with zero net external torque, the equation for conservation of angular momentum becomes

$$\sum_i \vec{L}_{\text{initial}} = \sum_i \vec{L}_{\text{final}}. \qquad \textbf{(10.38)}$$

For the special case of a rigid body rotating around a fixed axis of rotation, we find (since, in this case, $\vec{L} = I\vec{\omega}$):

$$I\vec{\omega} = I_0\vec{\omega}_0 \quad \left(\text{for } \vec{\tau}_{\text{net}} = 0\right), \qquad \textbf{(10.39)}$$

or, equivalently,

$$\frac{\omega}{\omega_0} = \frac{I_0}{I} \quad \left(\text{for } \vec{\tau}_{\text{net}} = 0\right).$$

This conservation law is the basis for the functioning of gyroscopes (Figure 10.30). Gyroscopes are objects (usually disks) that spin around a symmetry axis at high angular velocities. The axis of rotation is able to turn on ball bearings, almost without friction, and the suspension system is able to rotate freely in all directions. This freedom of motion ensures that no net external torque can act on the gyroscope. Without torque, the angular momentum of the gyroscope remains constant and thus points in the same direction, no matter what the object carrying the gyroscope does. Both airplanes and satellites rely on gyroscopes for navigation. The Hubble Space Telescope, for example, is equipped with six gyroscopes, at least three of which must work to allow the telescope to orient itself in space.

FIGURE 10.30 Toy gyroscope.

Photodisc/SuperStock

Equation 10.39 is also of importance in many sports, most notably gymnastics, platform diving (Figure 10.31), and figure skating. In all three sports, the athletes rearrange their bodies and thus adjust their moments of inertia to manipulate their rotation frequencies. The changing moment of inertia of a platform diver is illustrated in Figure 10.31. The platform diver starts her dive stretched out, as shown in Figure 10.31a. She then pulls her legs and arms into a tucked position, decreasing her moment of inertia, as shown in Figure 10.31b. She then completes several rotations as she falls. Before entering the water, she stretches out her arms and legs, increasing her moment of inertia and slowing her rotation, as shown in Figure 10.31c. Pulling her arms and legs into a tucked position reduces the moment of inertia of her body by some factor

$I' = I/k$, where $k > 1$. Conservation of angular momentum then increases the angular velocity by the same factor k : $\omega\prime = k\omega$. Thus, the diver can control the rate of rotation. Tucking in the arms and legs can increase the rate of rotation relative to that in the stretched-out position by more than a factor of 2.

(a) (b) (c)

EXAMPLE 10.7 Death of a Star

At the end of the life of a massive star more than five times as massive as the Sun, the core of the star consists almost entirely of the metal iron. Once this stage is reached, the core becomes unstable and collapses (as illustrated in Figure 10.32) in a process that lasts only about a second and is the initial phase of a supernova explosion. Among the most powerful energy-releasing events in the universe, supernova explosions are thought to be the source of most of the elements heavier than iron. The explosion throws off debris, including the heavier elements, into outer space, and may leave behind a neutron star, which consists of stellar material that is compressed to a density millions of times higher than the highest densities found on Earth.

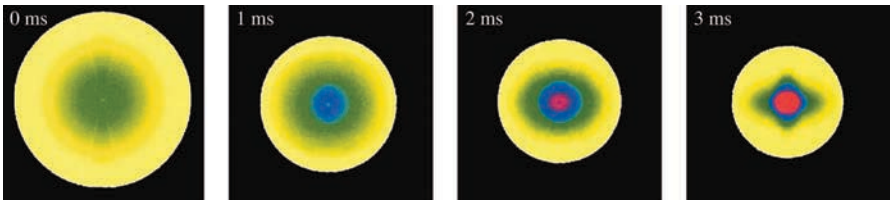

FIGURE 10.32 Computer simulation of the initial stages of the collapse of the core of a massive star. The different colors represent the varying density of the star's core, increasing from yellow through green and blue to red.

Wolfgang Bauer

PROBLEM

If the iron core initially spins 9.00 revolutions per day and if its radius decreases during the collapse by a factor of 700, what is the angular velocity of the core at the end of the collapse? (The assumption that the iron core has a constant density is not really justified. Computer simulations show that it falls off exponentially in the radial direction. However, the same simulations show that the moment of inertia of the iron core is

still approximately proportional to the square of its radius during the collapse process.)

SOLUTION

Because the collapse of the iron core occurs under the influence of its own gravitational pull, no net external torque acts on the core. Thus, according to equation 10.31, angular momentum is conserved. From equation 10.39 we then obtain

$$\frac{\omega}{\omega_0} = \frac{I_0}{I} = \frac{R_0^2}{R^2} = 700^2 = 4.90 \cdot 10^5.$$

With
$\omega_0 = 2\pi f_0 = 2\pi\left[(9 \text{ rev})/(24 \cdot 3600 \text{ s})\right] = 6.55 \cdot 10^{-4} \text{ rad/s},$
we obtain the magnitude of the final angular velocity:

$$\omega = 4.90 \cdot 10^5 \omega_0 = 4.90 \cdot 10^5 \left(6.55 \cdot 10^{-4} \text{ rad/s}\right) = 321 \text{ ra}$$

Thus, the neutron star that results from this collapse rotates with a rotational frequency of 51.0 rev/s.

DISCUSSION

Astronomers can observe the rotation of neutron stars, which are called *pulsars*. It is estimated that the fastest a pulsar can rotate when formed from a single-star supernova explosion is about 60 rev/s. One of the fastest known rotational frequencies for a pulsar is

$$f = 716 \text{ rev/s},$$

which corresponds to an angular speed of

$$\omega = 2\pi f = 2\pi\left(716 \text{ s}^{-1}\right) = 4500 \text{ rad/s}.$$

After its formation from a stellar collapse, such a fast-rotating pulsar increases its rotational frequency by taking matter from a companion star orbiting nearby.

SOLVED PROBLEM 10.5 Bullet Hitting a Pole

PROBLEM

A .22-caliber long rifle bullet of mass $m = 2.59$ g is shot from a gun during a Boy Scout merit badge exercise and is moving with a speed of 374.5 m/s when it collides with a pole of mass $M = 3.00$ kg and length $\ell = 2.00$ m. The pole is initially at rest, in a vertical position, and pivots about an axis going through its center of mass. The bullet embeds itself in the pole at a point that is $\frac{1}{3}$ of the length of the pole above the pivot point. As a result, the bullet-pole system starts rotating.

a) Find the angular momentum of the bullet-pole system after the collision.

b) What is the rotational kinetic energy of the pole and bullet after the collision?

SOLUTION

THINK

First, a seemingly trivial observation: If the bullet hit the pole right in the center, then there would be no rotation at all, because in that case the bullet has no angular momentum with respect to the pivot point at the center of the pole. But here the bullet hit the pole off-center, and the distance to the center times the bullet's momentum is the angular momentum. Angular momentum is conserved during the collision of the bullet with the pole (because there are no external torques during the collision!). Therefore, all we have to do to answer part (a) is calculate the initial angular momentum of the bullet.

SKETCH

Figure 10.33 includes a sketch indicating the distance from the pivot point to the point where the bullet hits the pole.

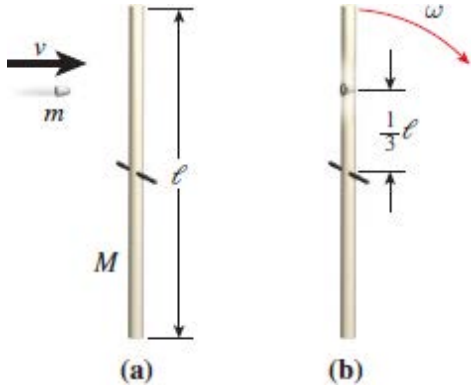

FIGURE 10.33 A bullet hits a pole and sticks.

RESEARCH

The momentum of the bullet is given by $p = mv$. When it hits the pole at the distance $\ell/3$ from the pole's center of mass, its angular momentum is $p\ell/3$. The moment of inertia of the pole is $M\ell^2/12$ and that of the bullet in the pole is $m(\ell/3)^2$. The kinetic energy of the bullet and pole together is all rotational, $K_\mathrm{r} = I\omega^2/2$, and the relationship among angular momentum, moment of inertia, and angular velocity is given by $L = I\omega$.

SIMPLIFY

a) The initial angular momentum is $L_\mathrm{i} = mv\ell/3$. The final angular momentum is the same, $L_\mathrm{f} = L_i = mv\ell/3$.

b) The total moment of inertia is $I = \left(M\ell^2/12\right) + \left(m\ell^2/9\right)$. The rotational kinetic energy is

$$K_\mathrm{r} = \frac{1}{2}I\omega^2 = \frac{1}{2}I^2\omega^2/I = \frac{1}{2}L^2/I = \frac{\quad\quad}{2((M/12)}$$

CALCULATE

a) $\boldsymbol{L_\mathrm{f} = \left(2.59 \cdot 10^{-3}\ \mathrm{kg}\right)(374.5\ \mathrm{m/s})(2.00\ \mathrm{m})/3 = 0.6466367\ \mathrm{kg\ m^2/s}.}$

b) $$K_\mathrm{r} = \frac{\left(0.6466367\ \mathrm{kg\ m^2/s}\right)^2}{2\left((3.00\ \mathrm{kg})/12 + \left(2.59 \cdot 10^{-3}\ \mathrm{kg}\right)/9\right)(2.00\ \mathrm{m})^2} = 0.2088291\ \mathrm{J}.$$

ROUND

The least precise input number was specified to three significant figures, to which we also round our final results:

a) $L_\mathrm{f} = 0.647\ \mathrm{kg\ m^2/s}$

b) $K_\mathrm{r} = 0.209\ \mathrm{J}$

DOUBLE-CHECK

Our results pass the minimum test in that the units work out properly. If you compare the initial translational kinetic energy of the bullet to the rotational kinetic energy just determined, you will find that $K_\mathrm{i} = \frac{1}{2}mv^2 = \frac{1}{2}\left(2.59 \cdot 10^{-3}\ \mathrm{kg}\right)(374.5\ \mathrm{m/s})^2 = 182\ \mathrm{J}$, a value that is larger than our answer for part (b) by a factor of ~ 280. This indicates that almost all of the kinetic energy is lost in this inelastic collision. A final issue to ponder: We have stated that the relationship $L = I\omega$ is only valid for an object rotating about an axis through its center of mass, a symmetry axis. Strictly speaking, the relationship is not exactly valid here, because the addition of the bullet to the upper part of the pole shifts the combined center of mass of the bullet-pole system slightly upward. However, since the mass of the bullet is only $\sim 0.1\%$ of that of the pole, this effect is negligible.

Concept Check 10.9

If the pole in Solved Problem 10.5 were made of steel so that the bullet bounced off backward, instead of becoming embedded in the pole, the rotational speed of the pole would be

a) higher than that found in Solved Problem 10.5.

b) the same as that found in Solved Problem 10.5.

c) lower than that found in Solved Problem 10.5.

10.8 Precession

Spinning tops were popular toys when your parents or grandparents were kids. When put in rapid rotational motion, they stand upright without falling down. What's more, if tilted at an angle relative to the vertical, they still do not fall down. Instead, the rotation axis moves on the surface of a cone as a function of time (Figure 10.34). This motion is called **precession.** What causes it?

FIGURE 10.34 A spinning top may tilt from the vertical but does not fall down.

Picture Partners/Alamy Stock Photo

First, we note that a spinning top has an angular momentum vector, $\vec{L}$, which is aligned with its symmetry axis, pointing either up or down, depending on whether it is spinning clockwise or counterclockwise (Figure 10.35). Because the top is tilted, its center of mass (marked with a black dot in Figure 10.35) is not located above the contact point with the support surface. The gravitational force acting on the center of mass then results in a torque, $\vec{\tau}$, about the contact point, as indicated in the figure; in this case, the torque vector points straight out of the page. The position vector, $\vec{r}$, of the center of mass, which helps determine the torque, is exactly

aligned with the angular momentum vector. The angle of the symmetry axis of the top with respect to the vertical is labeled ϕ in the figure. The angle between the gravitational force vector and the position vector is then $\pi - \phi$ (see Figure 10.35). Because $\sin(\pi - \phi) = \sin\phi$, we can write the magnitude of the torque as a function of the angle ϕ:

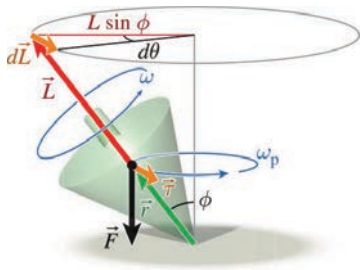

FIGURE 10.35
Precession of a spinning top.

$$\tau = rF\sin\phi = rmg\sin\phi.$$

Since $d\vec{L}/dt = \vec{\tau}$, the change in the angular momentum vector, $d\vec{L}$, points in the same direction as the torque and is thus perpendicular to the angular momentum vector. This effect forces the angular momentum vector to sweep along the surface of a cone of angle ϕ as a function of time, with the tip of the angular momentum vector following a circle in the horizontal plane, shown in gray in Figure 10.35.

We can even calculate the magnitude of the angular velocity, ω_{p}, for this precessional motion. Figure 10.35 indicates that the radius of the circle that the tip of the angular momentum vector sweeps out as a function of time is given by $L\sin\phi$. The magnitude of the differential change in angular momentum, dL, is the arc length of this circle, and it can be calculated as the product of the circle's radius and the differential angle swept out by the radius, $d\theta$:

$$dL = (L\sin\phi)d\theta.$$

Consequently, for the time derivative of the angular momentum, dL/dt, we find

$$\frac{dL}{dt} = (L \sin \phi) \frac{d\theta}{dt}.$$

The time derivative of the deflection angle, θ, is the angular velocity of precession, ω_p, Since $dL/dt = \tau$, we use the preceding equation and the expression for the torque, $\tau = rmg \sin \phi$, to obtain

$$rmg \sin \phi = \tau = \frac{dL}{dt} = (L \sin \phi) \frac{d\theta}{dt} = (L \sin \phi)\omega_{\mathrm{p}} \Rightarrow$$
$$\omega_{\mathrm{p}} = \frac{rmg \sin \phi}{L \sin \phi}.$$

Concept Check 10.10

Estimate the precessional angular speed of the wheel in Figure 10.36.

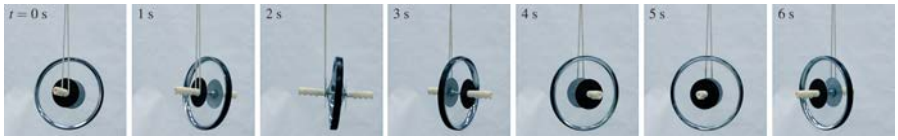

FIGURE 10.36 Precession of a rapidly spinning wheel suspended from a rope.

W. Bauer and G. D. Westfall

a) 0.01 rad/s

b) 0.6 rad/s

c) 5 rad/s

d) 10 rad/s

We see that the term $\sin\phi$ cancels out of the last expression, yielding $\omega_p = rmg/L$. The angular frequency of precession is the same for all values of ϕ, the tilt angle of the rotation axis! This result may seem a bit surprising, but experiments verify that it is indeed the case. For the final step, we use the fact that the angular momentum for a rigid object, L, is the product of the moment of inertia, I, and the angular velocity, ω. Thus, substituting $I\omega$ for L in the expression for the precessional angular speed, ω_p, gives us our final result:

$$\omega_p = \frac{rmg}{I\omega}. \qquad \textbf{(10.40)}$$

This formula reflects the interesting property that the precessional angular speed is inversely proportional to the angular speed of the spinning top. As the top slows down because of friction, its angular speed is gradually reduced, and therefore the precessional angular speed increases gradually. The faster and faster precession eventually causes the top to wobble and fall down.

Self-Test Opportunity 10.4

The wheel shown in Figure 10.36 has a mass of 2.5 kg, almost all of which is concentrated on the rim. It has a radius of 22 cm, and the distance between the suspension point and the center of mass is 5.0 cm. Estimate the angular speed with which it is spinning.

Precession is impressively demonstrated in the photo sequence of Figure 10.36. Here a rapidly spinning wheel is suspended off-center from a string attached to the ceiling. As you can see, the wheel does not fall down, as one would expect a nonspinning wheel

to do in the same situation, but slowly precesses around the suspension point.

10.9 Quantized Angular Momentum

To finish our discussion of angular momentum and rotation, let's consider the smallest quantity of angular momentum that an object can have. From the definition of the angular momentum of a point particle (equation 10.29), $\vec{L} = \vec{r} \times \vec{p}$ or $L = rp \sin\theta$, it would appear that there is no smallest amount of angular momentum, because either the distance to the rotation axis, r, or the momentum, p, can be reduced by a factor between 0 and 1, and the corresponding angular momentum will be reduced by the same factor.

However, for atoms and subatomic particles, the notion of a continuously variable angular momentum doesn't apply. Instead, a quantum of angular momentum is observed. This quantum of angular momentum is called **Planck's constant,** $h = 6.626 \cdot 10^{-34}$ J s. Very often Planck's constant appears in equations divided by the factor 2π, and physicists have given this ratio the symbol $\hbar$: $\hbar \equiv h/2\pi = 1.055 \cdot 10^{-34}$ J s. Chapter 36 will provide a full discussion of the experimental observations that led to the introduction of this fundamental constant. Here we simply note an amazing fact: All elementary particles have an intrinsic angular momentum, often called *spin,* which is either an integer multiple $(0, 1\hbar, 2\hbar, \ldots)$ or a half-integer multiple $\left(\frac{1}{2}\hbar, \frac{3}{2}\hbar, \cdots\right)$ of Planck's quantum of angular momentum. Astonishingly, the integer or half-integer spin values of particles make all the difference in the ways they interact with one another. Particles with integer-valued spins include photons, which are the elementary particles of light. Particles with half-integer values of spin include electrons, protons, and neutrons, the particles that constitute the building blocks of matter. We will return to the fundamental importance of angular momentum in atoms and subatomic particles in Chapters 37 through 40.

WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- An object's kinetic energy of rotation is given by $K = \frac{1}{2} I \omega^2$. This relationship holds for point particles as well as for solid objects.
- The moment of inertia for rotation of an object about an axis through the center of mass is defined as $I = \int_V r_\perp^2 \rho\left(\vec{r}\right) dV$, where $r_\perp$ is the perpendicular distance of the volume element dV to the axis of rotation and $\rho\left(\vec{r}\right)$ is the mass density.
- If the mass density is constant, the moment of inertia is $I = \frac{M}{V} \int_V r_\perp^2 \, dV$, where M is the total mass of the rotating object and V is its volume.
- The moment of inertia of all round objects is $I = cMR^2$, with $c \in [0, 1]$.
- The parallel-axis theorem states that the moment of inertia, $I_\parallel$, for rotation about an axis parallel to one through the center of mass is given by $I_\parallel = I_{\text{cm}} + Md^2$, where d is the distance between the two axes and I_{cm} is the moment of inertia for rotation about the axis through the center of mass.
- For an object that is rolling without slipping, the center of mass coordinate, r, and the rotation angle, θ, are related by $r = R\theta$, where R is the radius of the object.
- The kinetic energy of a rolling object is the sum of its translational and rotational kinetic energies: $K = K_{\text{trans}} + K_{\text{rot}} = \frac{1}{2} m v_{\text{cm}}^2 + \frac{1}{2} I_{\text{cm}} \omega^2 = \frac{1}{2}(1 + c) m v_{\text{cm}}^2$, with $c \in [0, 1]$ and with c depending on the shape of the object.

- Torque is defined as the vector product of the position vector and the force vector: $\overrightarrow{\tau} = \overrightarrow{r} \times \overrightarrow{F}$.
- The angular momentum of a point particle is defined as $\overrightarrow{L} = \overrightarrow{r} \times \overrightarrow{p}$.
- The rate of change of the angular momentum is equal to the torque: $\frac{d}{dt}\overrightarrow{L} = \overrightarrow{\tau}$. This is the rotational equivalent of Newton's Second Law.
- For rigid objects rotating about their symmetry axis, the angular momentum is $\overrightarrow{L} = I\overrightarrow{\omega}$, and the torque is $\overrightarrow{\tau} = I\overrightarrow{\alpha}$.
- In the case of vanishing net external torque, angular momentum is conserved: $I\overrightarrow{\omega} = I_0\overrightarrow{\omega_0}$ (for $\overrightarrow{\tau}_{\text{net}} = 0$).
- The equivalent quantities for linear and rotational motion are summarized in the table.

Quantity	Linear	Circular	Relationship

Quantity	Linear	Circular	Relationship
Displacement	$\vec{s}$	$\vec{\theta}$	$\vec{s} = r\vec{\theta}$
Velocity	$\vec{v}$	$\vec{\omega}$	$\vec{\omega} = \vec{r} \times \vec{v} / r^2$
Acceleration	$\vec{a}$	$\vec{\alpha}$	$\vec{a} = r\alpha\,\hat{t} - r\omega^2\hat{r}$ $a_t = r\alpha$ $a_c = \omega^2 r$
Momentum	$\vec{p}$	$\vec{L}$	$\vec{L} = \vec{r} \times \vec{p}$
Mass/moment of inertia	m	I	
Kinetic energy	$\frac{1}{2}mv^2$	$\frac{1}{2}I\omega^2$	
Force/torque	$\vec{F}$	$\vec{r}$	$\vec{\tau} = \vec{r} \times \vec{F}$

ANSWERS TO SELF-TEST OPPORTUNITIES

10.1 $I_{\parallel} = \frac{1}{12}mL^2 + m\left(\frac{L}{2}\right)^2 = mL^2\left(\frac{1}{12} + \frac{1}{4}\right) = \frac{1}{3}mL^2.$

10.2 The full can of soda is not a solid object and thus does not rotate as a solid cylinder. Instead, most of the liquid inside the can does not participate in the rotation even when the can reaches the bottom of the incline. The mass of the can itself is negligible compared to the mass of the liquid inside it. Therefore, a can of soda rolling down an incline approximates a mass sliding down an incline without friction. The constant c used in equation 10.15 is then close to zero, and so the can wins the race.

10.3 Newton's Third Law states that internal forces occur in equal and opposite pairs that act along the line of the separation of each pair of particles. Thus, the torque due to each pair of forces is zero. Summing up the torques from all the internal forces leads to zero net internal torque.

10.4 Since the mass is concentrated on the rim of the wheel, the wheel's moment of inertia is $I = mR^2$. With the aid of equation 10.40, we then obtain

$$\omega_{\mathrm{p}} = \frac{rmg}{mR^2\omega} = \frac{rg}{R^2\omega} = \frac{(0.050\ \mathrm{m})\left(9.81\ \mathrm{m/s^2}\right)}{(0.22\ \mathrm{m})^2(0.62\ \mathrm{rad/s})} = 16\ \mathrm{rad/s}$$

PROBLEM-SOLVING GUIDELINES: ROTATIONAL MOTION

1. Newton's Second Law and the work–kinetic energy theorem are powerful and complementary tools for solving a wide variety of problems in rotational mechanics. As a general guideline, you should try an approach based on Newton's Second Law and free-body diagrams when the problem involves calculating an angular acceleration. An approach based on the work–kinetic energy theorem is more useful when you need to calculate an angular speed.

2. Many concepts of translational motion are equally valid for rotational motion. For example, conservation of linear momentum applies when no external forces are present; conservation of angular momentum applies when no external torques are present. Remember the correspondences between translational and rotational quantities.

3. It is crucial to remember that the shape of an object is important in situations involving rotational motion. Be sure to use the correct formula for moment of inertia, which depends on the location of the axis of rotation as well as on the geometry of the object. Torque also depends on the location of the axis of symmetry; be sure to be consistent in calculating clockwise and counterclockwise torques.

4. Many relationships for rotational motion depend on the geometry of the situation—for example, the relationship of the linear velocity of a hanging weight to the angular velocity of the rope moving over a pulley. Sometimes the geometry of a situation changes in a problem, for example, if there is a different rotational inertia between starting and ending points of a rotation. Be sure you understand what quantities change during the course of any rotational motion.

5. Many physical situations involve rotating objects that roll, with or without slipping. If rolling without slipping is occurring,

you can relate linear and angular displacements, velocities, and accelerations to each other at points on the perimeter of the rolling object.

Page 323

6. The law of conservation of angular momentum is just as important for problems involving circular or rotational motion as the law of conservation of linear momentum is for problems involving straight-line motion. Thinking of a problem situation in terms of conserved angular momentum often provides a straightforward path to a solution, which otherwise would be difficult to obtain. But keep in mind that angular momentum is only conserved if the net external torque is zero.

MULTIPLE-CHOICE QUESTIONS

10.1 A circular object begins from rest and rolls without slipping down an incline, through a vertical distance of 4.0 m. When the object reaches the bottom, its translational velocity is 7.0 m/s. What is the constant c relating the moment of inertia to the mass and radius (see equation 10.11) of this object?

a) 0.80

b) 0.60

c) 0.40

d) 0.20

10.2 Two solid-steel balls, one small and one large, are on an inclined plane. The large ball has a diameter twice as large as that of the small ball. Starting from rest, the two balls roll without slipping down the incline until their centers of mass are 1 m below their starting positions. What is the speed of the large ball (v_{L}) relative to that of the small ball (v_{S}) after rolling 1 m?

a) $v_{\mathrm{L}} = 4v_{\mathrm{S}}$

b) $v_{\mathrm{L}} = 2v_{\mathrm{S}}$

c) $v_{\mathrm{L}} = v_{\mathrm{S}}$

d) $v_{\mathrm{L}} = 0.5v_{\mathrm{S}}$

e) $v_{\mathrm{L}} = 0.25v_{\mathrm{S}}$

10.3 A generator's flywheel, which is a homogeneous cylinder of radius R and mass M, rotates about its longitudinal axis. The linear velocity of a point on the rim (side) of the flywheel is v. What is the kinetic energy of the flywheel?

a) $K = \frac{1}{2}Mv^2$

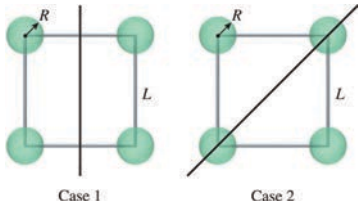
b) $K = \frac{1}{4}Mv^2$

c) $K = \frac{1}{2}Mv^2/R$

d) $K = \frac{1}{2}Mv^2R$

e) not given enough information to answer

10.4 Four hollow spheres, each with a mass of 1 kg and a radius $R = 10$ cm, are connected with massless rods to form a square with sides of length $L = 50$ cm. In case 1, the masses rotate about an axis that bisects two sides of the square. In case 2, the masses rotate about an axis that passes through the diagonal of the square, as shown in the figure. Compute the ratio of the moments of inertia, I_1/I_2, for the two cases.



a) $I_1/I_2 = 8$

b) $I_1/I_2 = 4$

c) $I_1/I_2 = 2$

d) $I_1/I_2 = 1$

e) $I_1/I_2 = 0.5$

10.5 If the hollow spheres of Question 10.4 were replaced by solid spheres of the same mass and radius, the ratio of the moments of inertia for the two cases would

a) increase.

b) decrease.

c) stay the same.

d) be zero.

10.6 An extended object consists of two point masses, m_1 and m_2, connected via a rigid massless rod of length L, as shown in the figure. The object is rotating at a constant angular velocity about an axis perpendicular to the page through the midpoint of the rod.

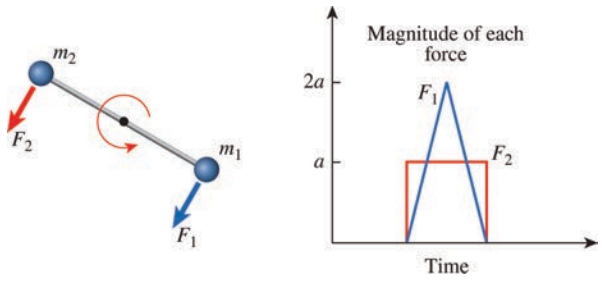
Two time-varying tangential forces, F_1 and F_2, are applied to m_1 and m_2, respectively. After the forces have been applied, what will happen to the angular velocity of the object?

a) It will increase.

b) It will decrease.

c) It will remain unchanged.

d) Not enough information is given to make a determination.



10.7 Consider a cylinder and a hollow cylinder, rotating about an axis going through their centers of mass. If both objects have the same mass and the same radius, which object will have the larger moment of inertia?

a) The moment of inertia will be the same for both objects.

b) The solid cylinder will have the larger moment of inertia because its mass is uniformly distributed.

c) The hollow cylinder will have the larger moment of inertia because its mass is located away from the axis of rotation.

10.8 A basketball of mass 610 g and circumference 76 cm is rolling without slipping across a gymnasium floor. Treating the ball as a hollow sphere, what fraction of its total kinetic energy is associated with its rotational motion?

a) 0.14

b) 0.19

c) 0.29

d) 0.40

e) 0.67

10.9 A solid sphere rolls without slipping down an incline, starting from rest. At the same time, a box starts from rest at the same altitude and slides down the same incline, with negligible friction. Which object arrives at the bottom first?

a) The solid sphere arrives first.

b) The box arrives first.

c) Both arrive at the same time.

d) It is impossible to determine.

10.10 A cylinder is rolling without slipping down a plane, which is inclined by an angle θ relative to the horizontal. What is the work done by the friction force while the cylinder travels a distance s along the plane (μ_s is the coefficient of static friction between the plane and the cylinder)?

a) $+\mu_s mgs \sin\theta$

b) $-\mu_s mgs \sin\theta$

c) $+mgs \sin\theta$

d) $-mgs \sin\theta$

e) No work is done.

10.11 A ball attached to the end of a string is swung in a vertical circle. The angular momentum of the ball at the top of the circular path is

a) greater than the angular momentum at the bottom of the circular path.

b) less than the angular momentum at the bottom of the circular path.

c) the same as the angular momentum at the bottom of the circular path.

10.12 You are unwinding a large spool of cable. As you pull on the cable with a constant tension, what happens to the angular

acceleration and angular velocity of the spool, assuming that the radius at which you are extracting the cable remains constant and there is no friction force?

a) Both increase as the spool unwinds.

b) Both decrease as the spool unwinds.

c) Angular acceleration increases, and angular velocity decreases.

d) Angular acceleration decreases, and angular velocity increases.

e) It is impossible to tell.

10.13 A disk of clay is rotating with angular velocity ω. A blob of clay is stuck to the outer rim of the disk, and it has a mass $\frac{1}{10}$ of that of the disk. If the blob detaches and flies off tangent to the outer rim of the disk, what is the angular velocity of the disk after the blob separates?

a) $\frac{5}{6}\omega$

b) $\frac{10}{11}\omega$

c) ω

d) $\frac{11}{10}\omega$

e) $\frac{6}{5}\omega$

10.14 An ice skater spins with her arms extended and then pulls her arms in and spins faster. Which statement is correct?

a) Her kinetic energy of rotation does not change because, by conservation of angular momentum, the fraction by which her angular velocity increases is the same as the fraction by which her rotational inertia decreases.

b) Her kinetic energy of rotation increases because of the work she does to pull her arms in.

c) Her kinetic energy of rotation decreases because of the decrease in her rotational inertia; she loses energy because she gradually gets tired.

10.15 An ice skater rotating on frictionless ice brings her hands into her body so that she rotates faster. Which, if any, of the

conservation laws hold?

a) conservation of mechanical energy and conservation of angular momentum

b) conservation of mechanical energy only

c) conservation of angular momentum only

d) neither conservation of mechanical energy nor conservation of angular momentum

10.16 If the iron core of a collapsing star initially spins with a rotational frequency of $f_0 = 3.20\ \text{s}^{-1}$, and if the core's radius decreases during the collapse by a factor of 22.7, what is the rotational frequency of the iron core at the end of the collapse?

a) 10.4 kHz

b) 1.66 kHz

c) 65.3 kHz

d) 0.460 kHz

e) 5.20 kHz

10.17 A bicycle is moving with a speed of 4.02 m/s. If the radius of the front wheel is 0.450 m, how long does it take for that wheel to make a complete revolution?

a) 0.703 s

b) 1.23 s

c) 2.34 s

d) 4.04 s

e) 6.78 s

10.18 Which one of the following statements concerning the moment of inertia of an extended rigid object is correct?

a) The moment of inertia is independent of the axis of rotation.

b) The moment of inertia depends on the axis of rotation.

c) The moment of inertia depends only on the mass of the object.

d) The moment of inertia depends only on the largest perpendicular dimension of the object.

10.19 The London Eye (basically a very large Ferris wheel) can be viewed as 32 pods, each with mass m_{p}, evenly spaced along the edge of a disk with mass m_{d} and radius R. Which of the following expressions gives the moment of inertia of the London Eye about the symmetry axis of the disk?

a) $(m_{\mathrm{p}} + m_{\mathrm{d}})R^2$

b) $\left(m_{\mathrm{p}} + \frac{1}{2}m_{\mathrm{d}}\right)R^2$

c) $\left(32m_{\mathrm{p}} + \frac{1}{2}m_{\mathrm{d}}\right)R^2$

d) $(32m_{\mathrm{p}} + m_{\mathrm{d}})R^2$

e) $\left(16m_{\mathrm{p}} + \frac{1}{2}m_{\mathrm{d}}\right)R^2$

10.20 A solid cylinder, a hollow cylinder, a solid sphere, and a hollow sphere are rolling without slipping. All four objects have the same mass and radius and are traveling with the same linear speed. Which one of the following statements is true?

a) The solid cylinder has the highest kinetic energy.

b) The hollow cylinder has the highest kinetic energy.

c) The solid sphere has the highest kinetic energy.

d) The hollow sphere has the highest kinetic energy.

e) All four objects have the same kinetic energy.

CONCEPTUAL QUESTIONS

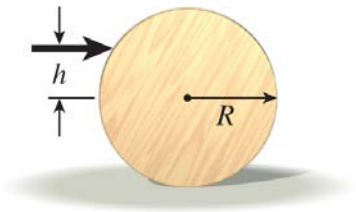
10.21 A uniform solid sphere of radius R, mass M, and moment of inertia $I = \frac{2}{5}MR^2$ is rolling without slipping along a horizontal surface. Its total kinetic energy is the sum of the energies associated with translation of the center of mass and rotation about the center of mass. Find the *fraction* of the sphere's total kinetic energy that is attributable to rotation.

10.22 A thin ring, a solid sphere, a hollow spherical shell, and a disk of uniform thickness are placed side by side on a wide ramp of length l and inclined at angle θ to the horizontal. At time $t = 0$, all four objects are released and roll without slipping on parallel paths down the ramp to the bottom. Friction and air resistance are negligible. Determine the order of finish of the race.

10.23 In another race, a solid sphere and a thin ring roll without slipping from rest down a ramp that makes angle θ with the horizontal. Find the ratio of their accelerations, $a_{\text{ring}}/a_{\text{sphere}}$.

10.24 A uniform solid sphere of mass m and radius r is placed on a ramp inclined at an angle θ to the horizontal. The coefficient of static friction between sphere and ramp is μ_s. Find the maximum value of θ for which the sphere will roll without slipping, starting from rest, in terms of the other quantities.

10.25 A round body of mass M, radius R, and moment of inertia I about its center of mass is struck a sharp horizontal blow along a line at height h above its center (with $0 \leq h \leq R$, of course). The body rolls away without slipping immediately after being struck. Calculate the ratio $I/(MR^2)$ for this body.



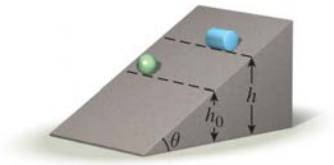
10.26 A projectile of mass m is launched from the origin at speed v_0 and an angle θ_0 above the horizontal. Air resistance is negligible.

a) Calculate the angular momentum of the projectile about the origin.

b) Calculate the rate of change of this angular momentum.

c) Calculate the torque acting on the projectile, about the origin, during its flight.

10.27 A solid sphere of radius R and mass M is placed at a height h_0 on an inclined plane of slope θ. When released, it rolls without slipping to the bottom of the incline. Next, a cylinder of same mass and radius is released on the same incline. From what height h should it be released in order to have the same speed as the sphere at the bottom?



10.28 It is harder to move a door if you lean against it (along the plane of the door) toward the hinge than if you lean against the door perpendicular to its plane. Why is this so?

10.29 A figure skater draws her arms in during a final spin. Since angular momentum is conserved, her angular velocity will increase. Is her rotational kinetic energy conserved during this process? If not, where does the extra energy come from or go to?

10.30 Does a particle traveling in a straight line have an angular momentum? Explain.

10.31 A cylinder with mass M and radius R is rolling without slipping through a distance s along an inclined plane that makes an angle θ with respect to the horizontal. Calculate the work done by (a) gravity, (b) the normal force, and (c) the frictional force.

10.32 Using the conservation of mechanical energy, calculate the final speed and the acceleration of a cylindrical object of mass M and radius R after it rolls a distance s without slipping along an inclined plane that makes an angle θ with respect to the horizontal.

10.33 A *couple* is a set of two forces of equal magnitude and opposite directions, whose lines of action are parallel but not identical. Prove that the net torque of a couple of forces is independent of the pivot point about which the torque is calculated and of the points along their lines of action where the two forces are applied.

10.34 Why does a figure skater pull in her arms while increasing her angular velocity in a tight spin?

10.35 To turn a motorcycle moving at high speed to the right, you momentarily turn the handlebars to the left to initiate the turn. After the turn is begun, you steer and lean to the right to complete the turn. Explain, as precisely as you can, how this countersteering begins the turn in the desired direction. (*Hint:* The wheels of a motorcycle in motion have a great deal of angular momentum.)

10.36 The Moon's tide-producing effect on the Earth is gradually slowing the rotation of the Earth, owing to tidal friction. Studies of corals from the Devonian Period indicate that the year was 400 days long in that period. What, if anything, does this indicate about the angular momentum of the Moon in the Devonian Period relative to its value at present?

10.37 A light rope passes over a light, frictionless pulley. One end is fastened to a bunch of bananas of mass M, and a monkey of the same mass clings to the other end. The monkey climbs the rope in an attempt to reach the bananas. The radius of the pulley is R.

a) Treating the monkey, bananas, rope, and pulley as a system, evaluate the net torque about the pulley axis.

b) Using the result of part (a), determine the total angular momentum about the pulley axis as a function of time.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Sections 10.1 and 10.2

10.38 A uniform solid cylinder of mass $M = 5.00$ kg is rolling without slipping along a horizontal surface. The velocity of its center of mass is 30.0 m/s. Calculate its energy.

10.39 Determine the moment of inertia for three children weighing 60.0 lb, 45.0 lb, and 80.0 lb sitting at different points on the edge of a rotating merry-go-round, which has a radius of 12.0 ft.

• **10.40** A 24.0-cm-long pen is tossed up in the air, reaching a maximum height of 1.20 m above its release point. On the way up, the pen makes 1.80 revolutions. Treating the pen as a thin uniform rod, calculate the ratio between the rotational kinetic energy and the translational kinetic energy at the instant the pen is released. Assume that the rotational speed does not change during the toss.

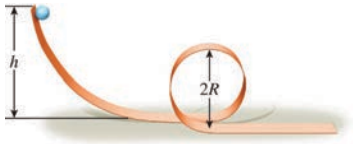
• **10.41** A solid ball and a hollow ball, each with a mass of 1.00 kg and radius of 0.100 m, start from rest and roll down a ramp of length 3.00 m at an incline of 35.0°. An ice cube of the same mass slides without friction down the same ramp.

a) Which ball will reach the bottom first? Explain!

b) Does the ice cube travel faster or slower than the solid ball at the base of the incline? Explain your reasoning.

c) What is the speed of the solid ball at the bottom of the incline?

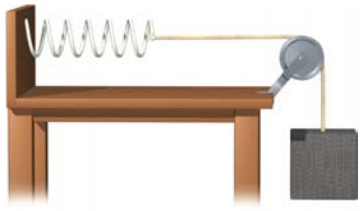
•**10.42** A solid ball of mass *m* and radius *r* rolls without slipping through a loop of radius *R*, as shown in the figure. From what height *h* should the ball be launched in order to make it through the loop without falling off the track?



••**10.43** The Crab pulsar $(m \approx 2 \cdot 10^{30}$ kg, $R = 12$ km$)$ is a neutron star located in the Crab Nebula. The rotation rate of the Crab pulsar is currently about 30 rotations per second, or 60π rad/s. The rotation rate of the pulsar, however, is decreasing;

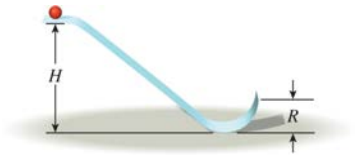
each year, the rotation period increases by 10^{-5} s. Justify the following statement: The loss in rotational energy of the pulsar is equivalent to 100,000 times the power output of the Sun. (The total power radiated by the Sun is about $4 \cdot 10^{26}$ W.)

••10.44 A block of mass $m = 4.00$ kg is attached to a spring ($k = 32.0$ N/m) by a rope that hangs over a pulley of mass $M = 8.00$ kg and radius $R = 5.00$ cm, as shown in the figure. Treating the pulley as a solid homogeneous disk, neglecting friction at the axle of the pulley, and assuming the system starts from rest with the spring at its natural length, find (a) the speed of the block after it falls 1.00 m, and (b) the maximum extension of the spring.



Section 10.3

•**10.45** A small circular object with mass m and radius r has a moment of inertia given by $I = cmr^2$. The object rolls without slipping along the track shown in the figure. The track ends with a ramp of height $R = 2.50$ m that launches the object vertically. The object starts from a height $H = 6.00$ m. To what maximum height will it rise after leaving the ramp if $c = 0.400$?



•**10.46** A uniform solid sphere of mass M and radius R is rolling without sliding along a level plane with a speed $v = 3.00$ m/s when it encounters a ramp that is at an angle $\theta = 23.0^\circ$ above the horizontal. Find the maximum distance that the sphere travels up the ramp in each case:

a) The ramp is frictionless, so the sphere continues to rotate with its initial angular speed until it reaches its maximum height.

b) The ramp provides enough friction to prevent the sphere from sliding, so both the linear and rotational motion stop when the object reaches its maximum height.

Section 10.4

•**10.47** A disk with a mass of 30.0 kg and a radius of 40.0 cm is mounted on a frictionless horizontal axle. A string is wound many times around the disk and then attached to a 70.0-kg block, as shown in the figure. Find the acceleration of the block, assuming that the string does not slip.

•**10.48** A force, $\vec{F} = \left(2\hat{x} + 3\hat{y}\right)$ N, is applied to an object at a point whose position vector with respect to the pivot point is $\vec{r} = \left(4\hat{x} + 4\hat{y} + 4\hat{z}\right)$ m. Calculate the torque created by the force about that pivot point.

••**10.49** A disk with a mass of 14.0 kg, a diameter of 30.0 cm, and a thickness of 8.00 cm is mounted on a rough horizontal axle as shown on the left in the figure. (There is a friction force between the axle and the disk.) The disk is initially at rest. A constant force, $F = 70.0$ N, is applied to the edge of the disk at an angle of 37.0°, as shown on the right in the figure. After 2.00 s, the force is reduced to $F = 24.0$ N, and the disk spins with a constant angular velocity.

a) What is the magnitude of the torque due to friction between the disk and the axle?

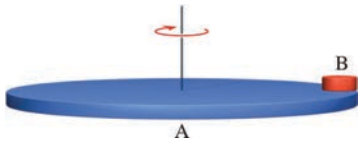
b) What is the angular velocity of the disk after 2.00 s?

c) What is the kinetic energy of the disk after 2.00 s?

Section 10.5

10.50 A thin uniform rod (length $= 1.00$ m, mass $= 2.00$ kg) is pivoted about a horizontal frictionless pin through one of its ends. The moment of inertia of the rod through this axis is $\frac{1}{3}mL^2$. The rod is released when it is 60.0° below the horizontal. What is the angular acceleration of the rod at the instant it is released?

10.51 An object made of two disk-shaped sections, A and B, as shown in the figure, is rotating about an axis through the center of disk A. The masses and the radii of disks A and B, respectively, are 2.00 kg and 0.200 kg and 25.0 cm and 2.50 cm.



a) Calculate the moment of inertia of the object.

b) If the axial torque due to friction is 0.200 N m, how long will it take for the object to come to a stop if it is rotating with an initial angular velocity of -2π rad/s?

•**10.52** You are the technical consultant for an action-adventure film in which a stunt calls for the hero to drop off a 20.0-m-tall building and land on the ground safely at a final vertical speed of 4.00 m/s. At the edge of the building's roof, there is a 100.-kg drum that is wound with a sufficiently long rope (of negligible mass), has a radius of 0.500 m, and is free to rotate about its cylindrical axis with a moment of inertia I_0. The script calls for the 50.0-kg stuntman to tie the rope around his waist and walk off the roof.

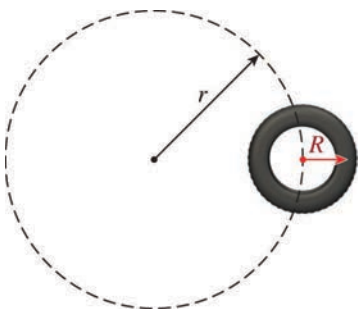
a) Determine an expression for the stuntman's linear acceleration in terms of his mass m, the drum's radius r, and the moment of inertia I_0.

b) Determine the required value of the stuntman's acceleration if he is to land safely at a speed of 4.00 m/s, and use this value to calculate the moment of inertia of the drum about its axis.

c) What is the angular acceleration of the drum?

d) How many revolutions does the drum make during the fall?

•**10.53** In a tire-throwing competition, a man holding a 23.5-kg car tire quickly swings the tire through three full turns and releases it, much like a discus thrower. The tire starts from rest and is then accelerated in a circular path. The orbital radius r for the tire's center of mass is 1.10 m, and the path is horizontal to the ground. The figure shows a top view of the tire's circular path, and the dot at the center marks the rotation axis. The man applies a constant torque of 20.0 N m to accelerate the tire at a constant angular acceleration. Assume that all of the tire's mass is at a radius $R = 0.350$ m from its center.

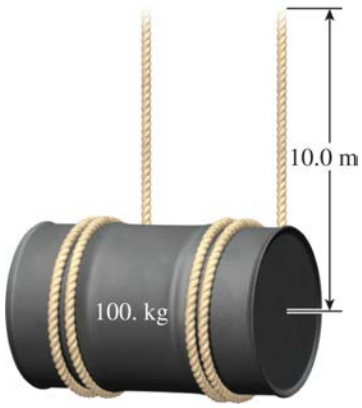


a) What is the time, t_{throw}, required for the tire to complete three full revolutions?

b) What is the final linear speed of the tire's center of mass (after three full revolutions)?

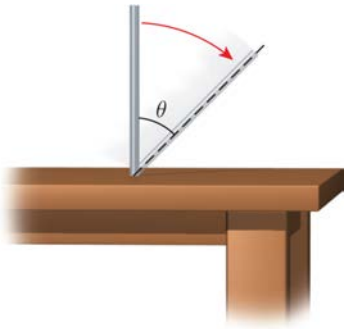
c) If, instead of assuming that all of the mass of the tire is at a distance 0.350 m from its center, you treat the tire as a hollow disk of inner radius 0.300 m and outer radius 0.400 m, how does this change your answers to parts (a) and (b)?

•**10.54** A 100.-kg barrel with a radius of 50.0 cm has two ropes wrapped around it, as shown in the figure. The barrel is released from rest, causing the ropes to unwind and the barrel to fall spinning toward the ground. What is the speed of the barrel after it has fallen a distance of 10.0 m? What is the tension in each rope? Assume that the barrel's mass is uniformly distributed and that the barrel rotates as a solid cylinder.



•**10.55** A wheel with $c = \frac{4}{9}$, a mass of 40.0 kg, and a rim radius of 30.0 cm is mounted vertically on a horizontal axis. A 2.00-kg mass is suspended from the wheel by a rope wound around the rim. Find the angular acceleration of the wheel when the mass is released.

••**10.56** A uniform rod of mass $M = 250.0$ g and length $L = 50.0$ cm stands vertically on a horizontal table. It is released from rest to fall.

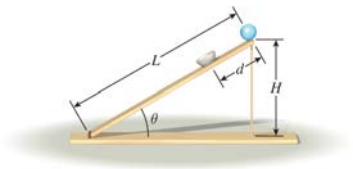


a) What forces are acting on the rod?

b) Calculate the angular speed of the rod, the vertical acceleration of the moving end of the rod, and the normal force exerted by the table on the rod as it makes an angle $\theta = 45.0^\circ$ with respect to the vertical.

c) If the rod falls onto the table without slipping, find the linear acceleration of the end point of the rod when it hits the table and compare it with g.

••**10.57** A demonstration setup consists of a uniform board of length L, hinged at the bottom end and elevated at an angle θ by means of a support stick. A ball rests at the elevated end, and a light cup is attached to the board at the distance d from the elevated end to catch the ball when the stick supporting the board is suddenly removed. You want to use a thin hinged board 1.00 m long and 10.0 cm wide, and you plan to have the vertical support stick located right at its elevated end.



a) What is the maximum length you can make the support stick so that the ball has a chance to be caught?

b) Assume that you choose to use the longest possible support stick placed at the elevated end of the board. What distance d from that end should the cup be located to ensure that the ball will be caught in the cup?

Section 10.6

•10.58 The flywheel of an old steam engine is a solid homogeneous metal disk of mass $M = 120.\ \text{kg}$ and radius $R = 80.0\ \text{cm}$. The engine rotates the wheel at 500. rpm. In an emergency, to bring the engine to a stop, the flywheel is disengaged from the engine and a brake pad is applied at the edge to provide a radially inward force $F = 100.\ \text{N}$. If the coefficient of kinetic friction between the pad and the flywheel is $\mu_\text{k} = 0.200$, how many revolutions does the flywheel make before coming to rest? How long does it take for the flywheel to come to rest? Calculate the work done by the torque during this time.

•10.59 The turbine and associated rotating parts of a jet engine have a total moment of inertia of $25.0\ \text{kg m}^2$. The turbine is accelerated uniformly from rest to an angular speed of 150. rad/s in a time of 25.0 s. Find

a) the angular acceleration,

b) the net torque required,

c) the angle turned through in 25.0 s,

d) the work done by the net torque, and

e) the kinetic energy of the turbine at the end of the 25.0 s.

Section 10.7

10.60 Two small 6.00-kg masses are joined by a string, which can be assumed to be massless. The string has a tangle in it, as shown in the figure. With the string tangled, the masses are separated by 1.00 m. The two masses are then made to rotate about their center of mass on a frictionless table at a rate of 5.00 rad/s. As they are rotating, the string untangles and lengthens to 1.40 m. What is the angular velocity of the masses after the string untangles?

•**10.61** It is sometimes said that if the entire population of China stood on chairs and jumped off simultaneously, it would alter the rotation of the Earth. Fortunately, physics gives us the tools to investigate such speculations.

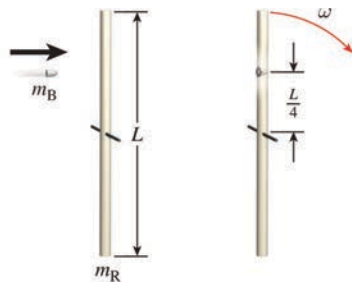
a) Calculate the moment of inertia of the Earth about its axis. For simplicity, treat the Earth as a uniform sphere of mass $m_{\mathrm{E}} = 5.977 \cdot 10^{24}$ kg and radius 6371 km.

b) Calculate an upper limit for the contribution by the population of China to the Earth's moment of inertia, by assuming that the whole group is at the Equator. Take the population of China to be 1.30 billion people, of average mass 70.0 kg.

c) Calculate the change in the contribution in part (b) associated with a 1.00-m simultaneous change in the radial position of the entire group.

d) Determine the fractional change in the length of the day the change in part (c) would produce.

•**10.62** A bullet of mass $m_{\mathrm{B}} = 1.00 \cdot 10^{-2}$ kg is moving with a speed of 100. m/s when it collides with a rod of mass $m_{\mathrm{R}} = 5.00$ kg and length $L = 1.00$ m (shown in the figure). The rod is initially at rest, in a vertical position, and pivots about an axis going through its center of mass. The bullet embeds itself in the rod at a distance $L/4$ from the pivot point. As a result, the bullet-rod system starts rotating.



a) Find the angular velocity, ω, of the bullet-rod system after the collision. You can neglect the width of the rod and can treat the bullet as a point mass.

b) How much kinetic energy is lost in the collision?

••10.63 A uniform solid sphere of radius R and mass M sits on a horizontal tabletop. A horizontally directed impulse with magnitude J is delivered to a spot on the ball a vertical distance h above the tabletop.

a) Determine the angular and translational velocity of the sphere just after the impulse is delivered.

b) Determine the distance h_0 at which the delivered impulse causes the ball to immediately roll without slipping.

•10.64 A circular platform of radius $R_\mathrm{p} = 4.00$ m and mass $M_\mathrm{p} = 400.$ kg rotates on frictionless air bearings about its vertical axis at 6.00 rpm. An 80.0-kg man standing at the very center of the platform starts walking (at $t = 0$) radially outward at a speed of 0.500 m/s with respect to the platform. Approximating the man by a vertical cylinder of radius $R_\mathrm{m} = 0.200$ m, determine an equation (specific expression) for the angular velocity of the platform as a function of time. What is the angular velocity when the man reaches the edge of the platform?

•10.65 A 25.0-kg boy stands 2.00 m from the center of a frictionless playground merry-go-round, which has a moment of inertia of 200. kg m^2. The boy begins to run in a circular path with a speed of 0.600 m/s relative to the ground.

a) Calculate the angular velocity of the merry-go-round.

b) Calculate the speed of the boy relative to the surface of the merry-go-round.

•**10.66** The Earth has an angular speed of $7.272 \cdot 10^{-5}$ rad/s in its rotation. Find the new angular speed if an asteroid $\left(m = 1.00 \cdot 10^{22} \text{ kg}\right)$ hits the Earth while traveling at a speed of $1.40 \cdot 10^{3}$ m/s (assume the asteroid is a point mass compared to the radius of the Earth) in each of the following cases:

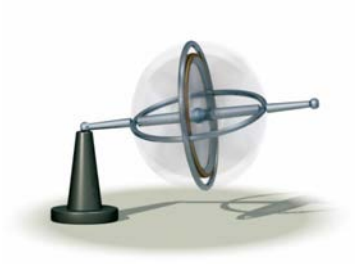
a) The asteroid hits the Earth dead center.

b) The asteroid hits the Earth nearly tangentially in the direction of Earth's rotation.

c) The asteroid hits the Earth nearly tangentially in the direction opposite to Earth's rotation.

Section 10.8

10.67 A demonstration gyroscope consists of a uniform disk with a 40.0-cm radius, mounted at the midpoint of a light 60.0-cm axle. The axle is supported at one end while in a horizontal position. How fast is the gyroscope precessing, in units of rad/s, if the disk is spinning around the axle at 30.0 rev/s?



Additional Exercises

10.68 Most stars maintain an equilibrium size by balancing two forces—an inward gravitational force and an outward force resulting from the star's nuclear reactions. When the star's fuel is spent, there is no counterbalance to the gravitational force. Whatever material is remaining collapses in on itself. Stars about the same size as the Sun become white dwarfs, which glow from leftover heat. Stars that have about three times the mass of the Sun compact into neutron stars. And a star with a mass greater than three times the Sun's mass collapses into a single point, called a *black hole*. In most cases, protons and electrons are fused together to form neutrons—this is the reason for the name *neutron star*. Neutron stars rotate very fast because of the conservation of angular momentum. Imagine a star of mass $5.00 \cdot 10^{30}$ kg and radius $9.50 \cdot 10^{8}$ m that rotates once in 30.0 days. Suppose this star undergoes gravitational collapse to form a neutron star of radius 10.0 km. Determine its rotation period.

10.69 In experiments at the Princeton Plasma Physics Laboratory, a plasma of hydrogen atoms is heated to over 500 million degrees Celsius (about 25 times hotter than the center of the Sun) and confined for tens of milliseconds by powerful magnetic fields (100,000 times greater than the Earth's magnetic field). For each experimental run, a huge amount of energy is required over a fraction of a second, which translates into a power requirement that would cause a blackout if electricity from the normal grid were to be used to power the experiment. Instead, kinetic energy is stored in a colossal flywheel, which is a spinning solid cylinder with a radius of 3.00 m and mass of $1.18 \cdot 10^{6}$ kg. Electrical energy from the power grid starts the flywheel spinning, and it takes 10.0 min to reach an angular speed of 1.95 rad/s. Once the flywheel reaches this angular speed, all of its energy can be drawn off very quickly to power an experimental run. What is the mechanical energy stored in the flywheel when it spins at 1.95 rad/s? What is the average torque required to accelerate the flywheel from rest to 1.95 rad/s in 10.0 min?

10.70 A 2.00-kg thin hoop with a 50.0-cm radius rolls down a 30.0° slope without slipping. If the hoop starts from rest at the top of

the slope, what is its translational velocity after it rolls 10.0 m along the slope?

10.71 An oxygen molecule (O_2) rotates in the *xy*-plane about the *z*-axis. The axis of rotation passes through the center of the molecule, perpendicular to its length. The mass of each oxygen atom is $2.66 \cdot 10^{-26}$ kg, and the average separation between the two atoms is $d = 1.21 \cdot 10^{-10}$ m.

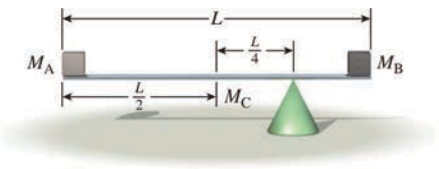
a) Calculate the moment of inertia of the molecule about the *z*-axis.

b) If the angular speed of the molecule about the *z*-axis is $4.60 \cdot 10^{12}$ rad/s, what is its rotational kinetic energy?

10.72 A 0.0500-kg bead slides on a wire bent into a circle of radius 0.400 m. You pluck the bead with a force tangent to the circle. What force is needed to give the bead an angular acceleration of $6.00\ \text{rad/s}^2$?

10.73 A professor doing a lecture demonstration stands at the center of a frictionless turntable, holding 5.00-kg masses in each hand with arms extended so that each mass is 1.20 m from his centerline. A (carefully selected!) student spins the professor up to a rotational frequency of 1.00 rpm. If he then pulls his arms in by his sides so that each mass is 0.300 m from his centerline, what is his new angular speed? Assume that his rotational inertia without the masses is $2.80\ \text{kg m}^2$, and neglect the effect on the rotational inertia of the position of his arms, since their mass is small compared to the mass of the body.

•**10.74** The system shown in the figure is held initially at rest. Calculate the angular acceleration of the system as soon as it is released. You can treat $M_A(1.00\ \text{kg})$ and $M_B(10.0\ \text{kg})$ as point masses located on either end of the rod of mass $M_C(20.0\ \text{kg})$ and length L (5.00 m).



•**10.75** A child builds a simple cart consisting of a 60.0 cm by 1.20 m sheet of plywood of mass 8.00 kg and four wheels, each 20.0 cm in diameter and with a mass of 2.00 kg. It is released from the top of a 15.0° incline that is 30.0 m long. Find the speed at the bottom. Assume that the wheels roll along the incline without slipping and that friction between the wheels and their axles can be neglected.

•**10.76** A CD has a mass of 15.0 g, an inner diameter of 1.50 cm, and an outer diameter of 11.9 cm. Suppose you toss it, causing it to spin at a rate of 4.30 revolutions per second.

a) Determine the moment of inertia of the CD, approximating its density as uniform.

b) If your fingers were in contact with the CD for 0.250 revolutions while it was acquiring its angular velocity and applied a constant torque to it, what was the magnitude of that torque?

•**10.77** A sheet of plywood 1.30 cm thick is used to make a cabinet door 55.0 cm wide by 79.0 cm tall, with hinges mounted on the vertical edge. A small 150.-g handle is mounted 45.0 cm from the lower hinge at the same height as that hinge. If the density of the plywood is 550. $\mathrm{kg/m^3}$, what is the moment of inertia of the door about the hinges? Neglect the contribution of hinge components to the moment of inertia.

•**10.78** A machine part is made from a uniform solid disk of radius R and mass M. A hole of radius $R/2$ is drilled into the disk, with the center of the hole at a distance $R/2$ from the center of the disk (the diameter of the hole spans from the center of the disk to its outer edge). What is the moment of inertia of this machine part about the center of the disk in terms of R and M?

•**10.79** A space station is to provide artificial gravity to support long-term habitation by astronauts and cosmonauts. It is designed as a large wheel, with all the compartments in the rim, which is to rotate at a speed that will provide an acceleration similar to that of terrestrial gravity for the astronauts (their feet will be on the inside of the outer wall of the space station and their heads will be pointing toward the hub). After the space station is assembled in orbit, its rotation will be started by the firing of a rocket motor

fixed to the outer rim, which fires tangentially to the rim. The radius of the space station is $R = 50.0$ m, and the mass is $M = 2.40 \cdot 10^5$ kg. If the thrust of the rocket motor is $F = 1.40 \cdot 10^2$ N, how long should the motor fire?

•**10.80** Many pulsars radiate radio-frequency or other radiation in a periodic manner and are bound to a companion star in what is known as a *binary pulsar system*. In 2003, a double pulsar system, PSR J0737-3039A and J0737-3039B, was discovered by astronomers at the Jodrell Bank Observatory in the United Kingdom. In this system, *both* stars are pulsars. The pulsar with the faster rotation period rotates once every 0.0230 s, while the other pulsar has a rotation period of 2.80 s. The faster pulsar has a mass 1.337 times that of the Sun, while the slower pulsar has a mass 1.250 times that of the Sun.

a) If each pulsar has a radius of 20.0 km, express the ratio of their rotational kinetic energies. Consider each star to be a uniform sphere with a fixed rotation period.

b) The orbits of the two pulsars about their common center of mass are rather eccentric (highly squashed ellipses), but an estimate of their average translational kinetic energy can be obtained by treating each orbit as circular with a radius equal to the mean distance from the system's center of mass. This radius is equal to $4.23 \cdot 10^8$ m for the larger star, and $4.54 \cdot 10^8$ m for the smaller star. If the orbital period is 2.40 h, calculate the ratio of rotational to translational kinetic energies for each star.

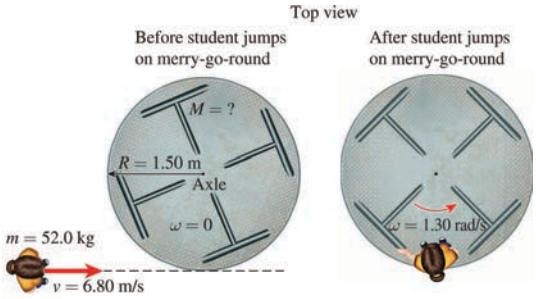
•**10.81** A student of mass 52.0 kg wants to measure the mass of a playground merry-go-round, which consists of a solid metal disk of radius $R = 1.50$ m that is mounted in a horizontal position on a low-friction axle. She tries an experiment: She runs with speed $v = 6.80$ m/s toward the outer rim of the merry-go-round and jumps on to the outer rim, as shown in the figure. The merry-go-round is initially at rest before the student jumps on and rotates at

1.30 rad/s immediately after she jumps on. You may assume that the student's mass is concentrated at a point.

a) What is the mass of the merry-go-round?

b) If it takes 35.0 s for the merry-go-round to come to a stop after the student has jumped on, what is the average torque due to friction in the axle?

c) How many times does the merry-go-round rotate before it stops, assuming that the torque due to friction is constant?



•**10.82** A ballistic pendulum consists of an arm of mass M and length $L = 0.480$ m. One end of the arm is pivoted so that the arm rotates freely in a vertical plane. Initially, the arm is motionless and hangs vertically from the pivot point. A projectile of the same mass M hits the lower end of the arm with a horizontal velocity of $V = 3.60$ m/s. The projectile remains stuck to the free end of the arm during their subsequent motion. Find the maximum angle to which the arm and attached mass will swing in each case:

a) The arm is treated as an ideal pendulum, with all of its mass concentrated as a point mass at the free end.

b) The arm is treated as a thin rigid rod, with its mass evenly distributed along its length.

••**10.83** A wagon wheel is made entirely of wood. Its components consist of a rim, 12 spokes, and a hub. The rim has mass 5.20 kg, outer radius 0.900 m, and inner radius 0.860 m. The hub is a solid cylinder with mass 3.40 kg and radius 0.120 m. The spokes are thin rods of mass 1.10 kg that extend from the hub to the inner side of the rim. Determine the constant $c = I/MR^2$ for this wagon wheel.

••**10.84** The figure shows a solid, homogeneous ball with radius R. Before falling to the floor, its center of mass is at rest, but it is

spinning with angular velocity ω_0 about a horizontal axis through its center. The lowest point of the ball is at a height h above the floor. When released, the ball falls under the influence of gravity and rebounds to a new height such that its lowest point is ah above the floor. The deformation of the ball and the floor due to the impact can be considered negligible; the impact time, though, is nonzero. The mass of the ball is m, and the coefficient of kinetic friction between the ball and the floor is μ_k. Ignore air resistance.

For the situation where the ball is slipping throughout the impact, find each of the following:

a) $\tan\theta$, where θ is the rebound angle indicated in the diagram,

b) the horizontal distance traveled in flight between the first and second impacts, and

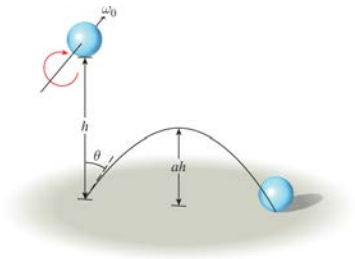
c) the minimum value of ω_0 for this situation.

For the situation where the ball stops slipping before the impact ends, find each of the following:

d) $\tan\theta$, and

e) the horizontal distance traveled in flight between the first and second impacts.

Taking both of the situations into account, sketch the variation of $\tan\theta$ with ω_0.



MULTI-VERSION EXERCISES

10.85 The propeller of a light plane has a length of 2.012 m and a mass of 17.36 kg. The propeller is rotating with a frequency of 3280. rpm. What is the rotational kinetic energy of the propeller? You can treat the propeller as a thin rod rotating about its center.

10.86 The propeller of a light plane has a length of 2.092 m and a mass of 17.56 kg. The rotational energy of the propeller is 422.8 kJ. What is the rotational frequency of the propeller (in rpm)? You can treat the propeller as a thin rod rotating about its center.

10.87 The propeller of a light plane has a length of 1.812 m and rotates at 2160. rpm. The rotational kinetic energy of the propeller is 124.3 kJ. What is the mass of the propeller? You can treat the propeller as a thin rod rotating about its center.

10.88 A golf ball with mass 45.90 g and diameter 42.60 mm is struck such that it moves with a speed of 51.85 m/s and rotates with a frequency of 2857 rpm. What is the kinetic energy of the golf ball?

10.89 A golf ball with mass 45.90 g and diameter 42.60 mm is struck such that it moves with a speed of 54.15 m/s while rotating. The golf ball has a kinetic energy of 67.67 J. What is the rotational frequency of the golf ball (in rpm)?

10.90 A golf ball with mass 45.90 g and diameter 42.60 mm is struck such that it rotates with a frequency of 2875 rpm and has a kinetic energy of 73.51 J as it moves. What is the linear speed of the golf ball?

10.91 A string is wrapped many times around a pulley and is connected to a block of mass $m_\mathrm{b} = 4.243$ kg, which is hanging vertically. The pulley consists of a wheel of radius 46.21 cm and mass $m_\mathrm{p} = 5.907$ kg, with spokes that have negligible mass. What is the magnitude of the acceleration of the block?

10.92 A string is wrapped many times around a pulley and is connected to a block of mass $m_\mathrm{b} = 4.701$ kg, which is hanging vertically. The pulley consists of a wheel of radius 47.49 cm, with spokes that have negligible mass. The block accelerates downward at 4.330 $\mathrm{m/s^2}$. What is the mass of the pulley, m_p?

10.93 A string is wrapped many times around a pulley and is connected to a block that is hanging vertically. The pulley consists of a wheel of radius 48.77 cm and mass $m_\mathrm{p} = 5.991$ kg, with spokes that have negligible mass. The block accelerates downward at 4.539 $\mathrm{m/s^2}$. What is the mass of the block, m_b?

The tallest building in the world as of 2008 was the Taipei 101 tower (Figure 11.1) in Taiwan, at 509 m (1670 ft) tall. Like any skyscraper, this building sways when winds near the top gust at high speeds. To minimize the motion, the Taipei 101 tower contains a mass damper

between the 87th and 92nd floors, consisting of a steel ball built from 5-in-thick disks. The damper has a mass of 660 metric tons, enough to reduce the tower's motion by about 40%. Restaurants and observation decks surround the damper, making it a leading tourist attraction.

Stability and safety are of prime importance in the design and construction of any building. In this chapter, we examine the conditions for static equilibrium, which occurs when an object is at rest, and subject to zero net forces and torques. However, as we will see, a structure must be able to resist outside forces that tend to set it in motion. The long-term stability of a large structure—a building, a

bridge, or a monument—depends on the builders' ability to judge how strong outside forces might be and to design the structure to withstand these forces.

WHAT WE WILL LEARN

- Static equilibrium is defined as mechanical equilibrium for the special case of an object at rest.
- An object (or a collection of objects) can be in static equilibrium only if the net external force is zero and the net external torque is zero.
- A necessary condition for static equilibrium is that the first derivative of the potential energy function is zero at the equilibrium point.
- Stable equilibrium is achieved at points where the potential energy function has a minimum.
- Unstable equilibrium occurs at points where the potential energy function has a maximum.
- Neutral equilibrium (or indifferent equilibrium or marginally stable equilibrium) exists at points where the first and second derivatives of the potential energy function are both zero.
- Equilibrium considerations are used to find otherwise unknown forces acting on an unmoving object or to find the forces required to prevent an object from moving.

11.1 Equilibrium Conditions

In Chapter 4, we saw that the necessary condition for static equilibrium is the absence of a net external force. In that case, Newton's First Law stipulates that an object stays at rest or moves with constant velocity. However, we often want to find the conditions necessary for a rigid object to stay at rest, in *static* equilibrium. An object (or collection of objects) is in **static equilibrium** if it is at rest and not experiencing translational or rotational motion. Figure 11.2a shows a famous example of a collection of objects in static equilibrium. Part of what makes this installation so amazing is that the eye does not want to accept that the configuration is stable. Figure 11.2b shows another example of a set of objects in static equilibrium that you can create at home or at a restaurant: The toothpick holds the spoon and fork on the rim of the glass. (For theatrical effect, the end of the toothpick was burnt after the "installation" was balanced.)

(a)

(b)

FIGURE 11.2 (a) This 420-kg installation created by Alexander Calder hangs from the ceiling at the National Gallery of Art (Washington, DC) in perfect static equilibrium. (b) You can create this installation, consisting of a fork, a spoon, and a toothpick balanced on a glass, at the dinner table.

a-b: W. Bauer and G. D. Westfall

The requirement of no translational or rotational motion means that the linear and angular velocities of an object in static equilibrium are always zero. The fact that the linear and angular velocities do not change with time implies that the linear and angular accelerations are also zero at all times. In Chapter 4, we saw that Newton's Second Law,

$$\overrightarrow{F}_{\text{net}} = m\overrightarrow{a}, \tag{11.1}$$

implies that if the linear acceleration, $\overrightarrow{\alpha}$, is zero, the external net force, $\overrightarrow{F}_{\text{net}}$, must be zero. Furthermore, we saw in Chapter 10 that Newton's Second Law for rotation,

$$\overrightarrow{\tau}_{\text{net}} = I\overrightarrow{\alpha}, \tag{11.2}$$

implies that if the angular acceleration, $\overrightarrow{\alpha}$, is zero, the external net torque, $\overrightarrow{\tau}_{\text{net}}$, must be zero. These facts lead to two conditions for static equilibrium.

Static Equilibrium Condition 1

An object can stay in static equilibrium only if the net force acting on it is zero:

$$\overrightarrow{F}_{\text{net}} = 0. \tag{11.3}$$

Static Equilibrium Condition 2

An object can stay in static equilibrium only if the net torque acting on it is zero:

$$\overrightarrow{\tau}_{\text{net}} = 0. \tag{11.4}$$

Even if Newton's First Law is satisfied (no net force acts on an object), and an object has no translational motion, it will still rotate if it experiences a net torque.

It is important to remember that torque is always defined with respect to a pivot point (the point where the axis of rotation intersects the plane defined by $\overrightarrow{F}$ and $\overrightarrow{r}$). When we compute the net torque, the pivot point must be the same for all forces involved in the calculation. If we try to solve a static equilibrium problem, with vanishing net torque, the net torque has to be zero for any pivot point chosen. Thus, we have the freedom to select a pivot point that best suits our purpose. A clever selection of a pivot point is often the key to a quick solution. For example, if an unknown force is present in the problem, we can select the point where the force acts as the pivot point. Then, that force will not enter into the torque equation because it has a moment arm of length zero.

If an object is supported from a pin located directly above its center of mass, as in Figure 11.3a (where the red dot marks the center of mass), then the object stays balanced; that is, it does not start to rotate. Why? Because in this case only two forces act on the object—the force of gravity, $\vec{F}_g$ (blue arrow), and the vertical supporting force $\vec{N}$ (green arrow), from the pin—and they lie on the same line (yellow line in Figure 11.3a). The two forces cancel each other out and produce no net torque, resulting in static equilibrium; the object is in balance.

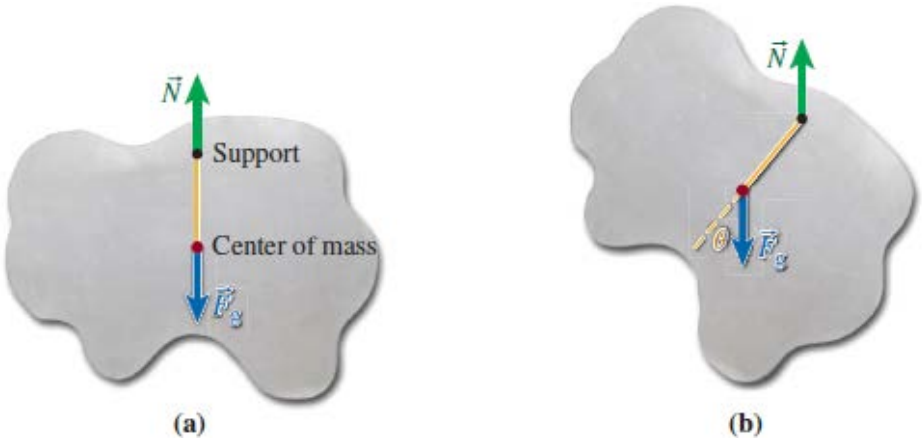

FIGURE 11.3 (a) This object experiences zero net torque, because it is supported from a pin located exactly above the center of mass. (b) A net torque results when the center of mass of the same object is at a location not exactly below the support point.

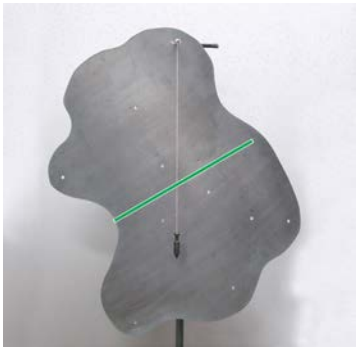
On the other hand, if an object is supported in the same way from a pin but its center of mass is not below the support point, then the situation is that shown in Figure 11.3b. The normal and gravitational force vectors still point in opposite directions; however, a nonzero net torque now acts, because the angle θ between the gravitational force vector, $\vec{F}_g$, and the moment arm (directed along the yellow line) is not zero any more. This torque violates the condition that the net torque must be zero for static equilibrium. However, suspending an object from different points is a practical method for finding the

center of mass of the object, even a strangely shaped object like the one in Figure 11.3.

Experimentally Locating the Center of Mass

To locate an object's center of mass experimentally, we can support the object from a pin in such a way that it can rotate freely around the pin and then let it come to rest. Once the object has come to rest, its center of mass is located on the line directly below the pin. We hang a weight (a plumb bob in Figure 11.4) from the same pin used to support the object, and it identifies the line. We mark this line on the object. If we do this for two different support points, the intersection of the two lines will mark the precise location of the center of mass.

(a)



(b)

FIGURE 11.4
Finding the center of mass for an arbitrarily shaped object.

a-b: W. Bauer and G. D. Westfall

You can use another technique to determine the location of the center of mass for many objects (see Figure 11.5). You simply support the object on two fingers placed in such a way that the center of mass is located somewhere between them. (If this is not the case, you will know right away, because the object will fall.) Then slowly slide the fingers closer to each other. At the point where they meet, they are directly below the center of mass, and the object is balanced on top.

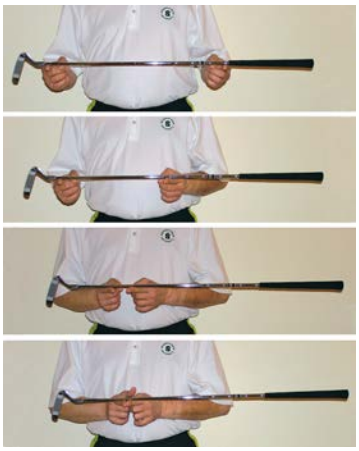


FIGURE 11.5
Determining the center of mass of a golf club experimentally.

W. Bauer and G. D. Westfall

Why does this technique work? The finger that is closer to the center of mass exerts a larger normal force on the object. Thus, when moving, this finger exerts a larger friction force on the object than the finger that is farther away. Consequently, if the fingers slide toward each other, the finger that is closer to the center of mass will take the suspended object along with it. This continues until the other finger becomes closer to the center of mass, when the effect is reversed. In this way, the two fingers always keep the center of mass located between them. When the fingers are next to each other, the center of mass is located.

In Figure 4.6, showing a hand holding up a laptop computer, the force vector $\overrightarrow{N}$ exerted by the hand on the laptop acted at the laptop's center, just like the gravitational force vector but in the opposite

direction. This placement is necessary. For a hand to hold up a laptop computer, it must be placed directly below the computer's center of mass. Otherwise, if the center of mass were not supported from directly below, the computer would tip over.

Equilibrium Equations

With a qualitative understanding of the concepts and conditions for static equilibrium, we can formulate the equilibrium conditions for a more quantitative analysis. In Chapter 4, we found that the condition of zero net force translates into three independent equations in three-dimensional space, one for each Cartesian component of the zero net force (refer to equation 11.3). In addition, the condition of zero net torque in three dimensions also implies three equations for the components of the net torque (refer to equation 11.4), representing independent rotations about the three possible axes of rotation, which are all perpendicular to each other. In this chapter, we will not deal with the three-dimensional situations (involving six equations), but rather will concentrate on problems of static equilibrium in two-dimensional space, that is, a plane. In a plane, there are two independent translational degrees of freedom for a rigid body (in the *x*- and the *y*-directions) and one possible rotation, either clockwise or counterclockwise around a rotation axis that is perpendicular to the plane. Thus, the two equations for the net force components are

$$F_{\text{net},x} = \sum_{i=1}^{n} F_{i,x} = F_{1,x} + F_{2,x} + \cdots + F_{n,x} = 0 \quad \textbf{(11.5)}$$

$$F_{\text{net},y} = \sum_{i=1}^{n} F_{i,y} = F_{1,y} + F_{2,y} + \cdots + F_{n,y} = 0. \quad \textbf{(11.6)}$$

In Chapter 10, the net torque about a fixed axis of rotation was defined as the difference between the sum of the counterclockwise torques and the sum of the clockwise torques. The static equilibrium condition of zero net torque about each axis of rotation can thus be written as

$$\boldsymbol{\tau}_{\text{net}} = \sum_{i} \boldsymbol{\tau}_{\text{counterclockwise},i} - \sum_{j} \boldsymbol{\tau}_{\text{clockwise},j} = 0. \quad \textbf{(11.7)}$$

These three equations (11.5 through 11.7) form the basis for the quantitative analysis of static equilibrium in the problems in this chapter.

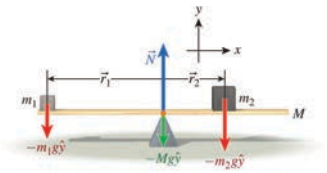
11.2 Examples Involving Static Equilibrium

The two conditions for static equilibrium (zero net force and zero net torque) are all we need to solve a very large class of problems involving static equilibrium. We do not need calculus to solve these problems; all the calculations use only algebra and trigonometry. Let's start with an example for which the answer seems obvious. This will provide practice with the method and show that it leads to the right answer.

EXAMPLE 11.1 Seesaw

A playground seesaw consists of a pivot and a bar, of mass M, that is placed on the pivot so that the ends can move up and down freely (Figure 11.6a). If an object of mass m_1 is placed on one end of the bar at a distance r_1 from the pivot point, as shown in Figure 11.6b, that end goes down, simply because of the force and torque that the object exerts on it.

(a)



(b)

FIGURE 11.6 (a) A playground seesaw; (b) free-body diagram showing forces and moment arms.

a: Bill Grant/Alamy Stock Photo

PROBLEM 1

Where do we have to place an object of mass m_2 (assumed to be equal to the mass of m_1 to get the seesaw to balance, so the bar is horizontal and neither end touches the ground?

SOLUTION 1

Figure 11.6b is a free-body diagram of the bar showing the forces acting on it and the points where they act. The force that m_1 exerts on the bar is simply $m_1 g$, acting downward as shown in Figure 11.6b. The same is true for the force that m_2 exerts on the bar. In addition, because the bar has a mass M of its own, it experiences a gravitational force, Mg. The gravitational force acts at the center of mass of the bar, right in the middle of the bar. The final force acting on the bar is the normal force, N, exerted by the bar's support. It acts exactly at the axle of the seesaw (marked with an orange dot).

The equilibrium equation for the y-components of the forces leads to an expression for the value of the normal force:

$$F_{\text{net},y} = \sum_i F_{i,y} = -m_1 g - m_2 g - Mg + N = 0$$
$$\Rightarrow N = g(m_1 + m_2 + M).$$

The signs in front of the individual force components indicate whether they act upward (positive) or downward (negative).

Because all forces act in the y-direction, it is not necessary to write equations for the net force components in the x- or z-directions.

Now we can consider the net torque. The selection of the proper pivot point can make our computations simple. For a seesaw, the natural selection is at the axle, the point marked with an orange dot in the center of the bar in Figure 11.6b. Because the normal force, N, and the weight of the bar, Mg, act exactly through this point, their moment arms have length zero. Thus, these two forces do not contribute to the torque equation if this is selected as the pivot point. The forces $F_1 = m_1 g$ and $F_2 = m_2 g$ are the only ones contributing torques: F_1 generates a counterclockwise torque, and F_2 a clockwise torque. The torque equation is then

$$\begin{aligned}\tau_{\text{net}} &= \sum_i \tau_{\text{counterclockwise},i} - \sum_j \tau_{\text{clockwise},j} \\ &= m_1 g r_1 \sin 90^\circ - m_2 g r_2 \sin 90^\circ = 0 \\ &\Rightarrow m_2 r_2 = m_1 r_1 \\ &\Rightarrow r_2 = r_1 . \frac{m_1}{m_2}\end{aligned} \qquad \text{(i)}$$

Even though they equal 1 and thus have no effect, the factors sin 90° are included above as a reminder that the angle between force and moment arm usually affects the calculation of the torques.

The question was where to put m_2 for the case that the two masses were the same; the answer is $r_2 = r_1$ in this case. This expected result shows that our systematic way of approaching the solution works in this easily verifiable case.

PROBLEM 2

How big does m_2 need to be to balance m_1 if $r_1 = 3r_2$, that is, if m_2 is three times closer to the pivot point than m_1?

SOLUTION 2

We use the same free-body diagram (Figure 11.6b) and arrive at the same general equation for the masses and distances. Solving equation (i) for m_2 gives

$$\begin{aligned} m_2 r_2 &= m_1 r_1 \\ \Rightarrow m_2 &= m_1 \frac{r_1}{r_2}. \end{aligned}$$

Using $r_1 = 3r_2$, we obtain

$$m_2 = m_1 \frac{r_1}{r_2} = m_1 \frac{3r_2}{r_2} = 3m_1.$$

For this case, we find that the mass of m_2 has to be three times that of m_1 to establish static equilibrium.

Self-Test Opportunity 11.1

Suppose that the pivot point for the seesaw in Problem 1 of Example 11.1 is placed instead below the center of mass of m_2. Show that this leads to the same result.

As Example 11.1 shows, a clever choice of a pivot point can often greatly simplify a solution. It is important, however, to realize that one can use *any* pivot point. If the torques are balanced about any pivot point, they are balanced about *all* pivot points. Thus, if we change the pivot point, it can make the calculations more complicated in certain situations, but the end result of the calculation will not change.

EXAMPLE 11.2 Force on Biceps

Suppose you are holding a barbell in your hand, as shown in Figure 11.7a. Your biceps supports your forearm. The biceps is attached to the bone of the forearm at a distance $r_b = 2.0$ cm from the elbow, as shown in Figure 11.7b. The mass of your forearm is 0.85 kg. The length of your forearm is 31 cm. Your forearm makes an angle $\theta = 75^\circ$ with the vertical, as shown in Figure 11.7b. The barbell has a mass of 15 kg.

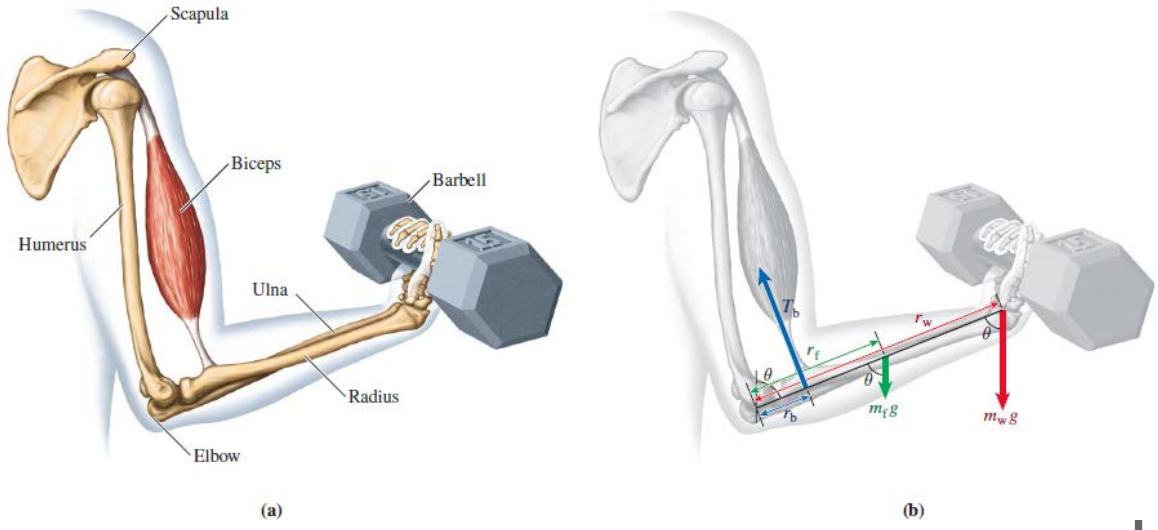


FIGURE 11.7 (a) A human arm holding a barbell. (b) Forces and moment arms for a human arm holding a barbell.

PROBLEM

What is the force that the biceps must exert to hold up your forearm and the barbell? Assume that the biceps exerts a force perpendicular to the forearm at the point of attachment.

SOLUTION

The pivot point is the elbow. The net torque on your forearm must be zero, so the counterclockwise torque must equal the clockwise torque:

$$\sum_i \tau_{\text{counterclocwise},i} = \sum_j \tau_{\text{clockwise},j}.$$

The counterclockwise torque is provided by the biceps:

$$\sum_i \tau_{\text{counterclockwise},i} = T_\text{b} r_\text{b} \sin 90^\circ = T_\text{b} r_\text{b},$$

where T_b is the force exerted by the biceps and r_b is the moment arm for the force exerted by the biceps. The clockwise torque is the sum of the torque exerted by the weight of the forearm and the torque exerted by the barbell:

$$\sum_j \tau_{\text{clockwise},j} = m_\text{f} g r_\text{f} \sin\theta + m_w g r_w \sin\theta,$$

where m_f is the mass of the forearm, r_f is the moment arm for the force exerted by the weight of the forearm, m_w is the mass of the barbell, and r_w is the moment arm of the force exerted by the weight of the barbell. We take the r_w to be equal to the length of the forearm and r_f to be half of that length, or $r_\text{w}/2$. Equating the counterclockwise torque and the clockwise torque gives us

$$T_\text{b} r_\text{b} = m_\text{f} g r_\text{f} \sin\theta + m_w g r_w \sin\theta.$$

Solving for the force exerted by the biceps, we obtain

$$T_\text{b} = \frac{m_\text{f} g r_\text{f} \sin\theta + m_\text{w} g r_\text{w} \sin\theta}{r_\text{b}} = g \sin\theta \left(\frac{m_\text{f} r_\text{f} + m_\text{w} r_\text{w}}{r_\text{b}} \right).$$

Putting in the given numbers gives the force exerted by the biceps

$$
\begin{aligned}
T_{\mathrm{b}} &= \mathrm{g}\sin\theta\left(\frac{m_{\mathrm{f}}r_{\mathrm{f}} + m_{\mathrm{w}}r_{\mathrm{w}}}{r_{\mathrm{b}}}\right) \\
&= \left(9.81\ \mathrm{m/s^2}\right)(\sin 75^\circ)\left(\frac{(0.85\ \mathrm{kg})\left(\frac{0.31\ \mathrm{m}}{2}\right) + (15\ \mathrm{kg}}{0.020\ \mathrm{m}}\right. \\
&= 2300\ \mathrm{N}.
\end{aligned}
$$

You may wonder why evolution gave the biceps such a huge mechanical disadvantage. Apparently, it was more advantageous to be able to swing the arms a long distance (and therefore moving the hands with greater speed!) while the biceps exerted a comparatively huge force than for the biceps to be able to exert a smaller force and move the arms a shorter distance. This is in contrast, by the way, to the jaw muscles, which have evolved the ability to crunch tough food with huge force by attaching to the jaw farther from the pivot point and closer to the point where the force is applied by the teeth.

Self-Test Opportunity 11.2

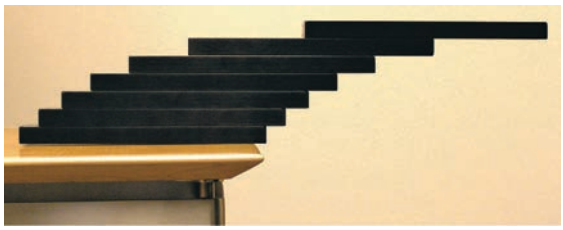
In Example 11.2, suppose you hold the barbell so that your forearm makes an angle of 180° with the vertical. Why is it that you can still lift the barbell?

The following example for static equilibrium also applies the formulas for computing the center of mass that were introduced in Chapter 8, and at the same time has a very surprising outcome.

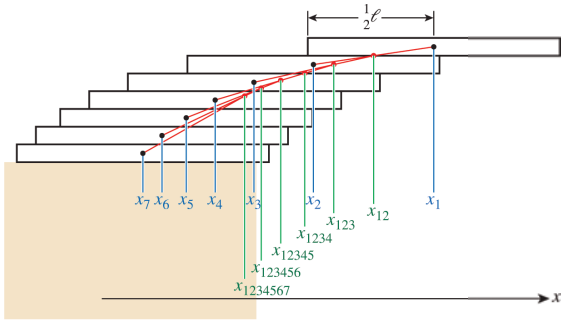
EXAMPLE 11.3 Stacking Blocks

PROBLEM

Consider a collection of identical blocks stacked at the edge of a table (Figure 11.8). How far out can we push the leading edge of the top block without the pile falling off?



(a)



(b)

FIGURE 11.8 (a) Stack of seven identical blocks piled on a table-note that the left edge of the top block is to the right of the right edge of the table. (b) Positions of the centers of mass of the individual blocks (x_1 through x_7) and locations of the combined centers of mass of the topmost blocks (x_{12} through $x_{1234567}$.)

a: W. Bauer and G. D. Westfall

SOLUTION

Let's start with one block. If the block has length ℓ and uniform mass density, then its center of mass is located at $\frac{1}{2}\ell$. Clearly, it

can stay at rest as long as at least half of it is on the table, with its center of mass supported by the table from below. The block can stick out an infinitesimal amount less than $\frac{1}{2}\ell$ beyond the support, and it will remain at rest.

Next, we consider two identical blocks. If we call the x-coordinate of the center of mass of the upper block x_1 and that of the lower block x_2, we obtain for the x-coordinate of the center of mass of the combined system, according to Section 8.1,

$$x_{12} = \frac{x_1 m_1 + x_2 m_2}{m_1 + m_2}.$$

For identical blocks, $m_1 = m_2$, which simplifies the expression for x_{12} to

$$x_{12} = \tfrac{1}{2}(x_1 + x_2).$$

Since $x_1 = x_2 + \frac{1}{2}\ell$ in the limiting case that the center of mass of the first block is still supported from below by the second block, we obtain

$$x_{12} = \tfrac{1}{2}(x_1 + x_2) = \tfrac{1}{2}\left(\left(x_2 + \tfrac{1}{2}\ell\right) + x_2\right) = x_2 + \tfrac{1}{4}\ell. \quad \text{(i)}$$

Now we can go to three blocks. The top two blocks will not topple if the combined center of mass, x_{12}, is supported from below. Shifting x_{12} to the very edge of the third block, we obtain $x_{12} = x_3 + \frac{1}{2}\ell$. Combining this with equation (i), we have

$$x_{12} = x_2 + \tfrac{1}{4}\ell = x_3 + \tfrac{1}{2}\ell \Rightarrow x_2 = x_3 + \tfrac{1}{4}\ell.$$

Note that equation (i) is still valid after the shift because we have expressed x_{12} in terms of x_2 and because x_{12} and x_2 change by the same amount when the two blocks move together. We can now calculate the center of mass for the three blocks in the same

way as before, by applying the same principle to find the new combined center of mass:

$$x_{123} = \frac{x_{12}(2m) + (x_3 m)}{2m + m} = \tfrac{2}{3}x_{12} + \tfrac{1}{3}x_3 = \tfrac{2}{3}\left(x_3 + \tfrac{1}{2}\ell\right.$$

Requiring that the top three blocks are supported by the fourth block from below results in $x_{123} = x_4 + \frac{1}{2}\ell$. Combined with equation (ii), this establishes

$$x_{123} = x_3 + \tfrac{1}{3}\ell = x_4 + \tfrac{1}{2}\ell \Rightarrow x_3 = x_4 \tfrac{1}{6}\ell.$$

You can see how this series continues. If we have $n - 1$ blocks supported in this way by the *n*th block, then the coordinates of the $(n - 1)$ st and *n*th block are related as follows:

$$x_{n-1} = x_n + \frac{\ell}{2n - 2}.$$

We can now add up all the terms and find out how far away x_1 can be from the edge:

$$x_1 = x_2 + \tfrac{1}{2}l = x_3 + \tfrac{1}{4}l + \tfrac{1}{2}l = x_4 + \tfrac{1}{6}l + \tfrac{1}{4}l + \tfrac{1}{2}l = \cdots$$

You may remember from calculus that the sum $\sum_{i=1}^{n} i^{-1}$ does not converge, that is, does not have an upper limit for $n \to \infty$. This gives the astonishing result that x_1 can move *infinitely* far away from the table's edge, provided there are enough blocks under it and that the edge of the table can support their weight without significant deformation! (But see Self-Test Opportunity 11.3 to put this *infinity* into perspective.) Figure 11.8a shows only seven blocks stacked on a table, and the left edge of the top block is already to the right of the right edge of the table.

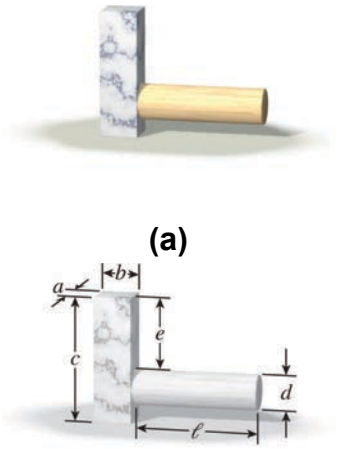
The following problem, involving a composite extended object, serves to review the calculation of the center of mass of such objects, which was introduced in Chapter 8.

Self-Test Opportunity 11.3

Suppose you had 10,000 identical blocks of height 4.0 cm and length 15.0 cm. If you arranged them in the way demonstrated in Example 11.3, how far would the right edge of the top block stick out?

SOLVED PROBLEM 11.1 An Abstract Sculpture

An alumnus of your university has donated a sculpture to be displayed in the atrium of the new physics building. The sculpture consists of a rectangular block of marble of dimensions $a = 0.71$ m, $b = 0.71$ m, and $c = 2.74$ m and a cylinder of wood with length $\ell = 2.84$ m and diameter $d = 0.71$ m, which is attached to the marble so that its upper edge is a distance $e = 1.47$ m from the top of the marble block (Figure 11.9).



(a)

(b)

FIGURE 11.9 (a) A wood and marble sculpture; (b) diagram of the sculpture with dimensions labeled.

PROBLEM

If the mass density of the marble is $2.85 \cdot 10^3$ kg/m^3 and that of the wood is $4.40 \cdot 10^2$ kg/m^3, can the sculpture stand upright on

the floor of the atrium, or does it need to be supported by some kind of bracing?

SOLUTION

THINK

Chapter 8 showed that a condition for stability of an object is that the object's center of mass needs to be directly supported from below. In order to decide if the sculpture can stand upright without additional support, we therefore need to determine the location of the center of mass of the sculpture and find out if it is located at a point inside the marble block. Since the floor supports the block from below, the sculpture will be able to stand upright if this is the case. If the center of mass of the sculpture is located outside the marble block, the sculpture will need bracing.

SKETCH

We draw a side view of the sculpture (Figure 11.10), representing the marble block and the wooden cylinder by rectangles. The sketch also indicates a coordinate system with a horizontal x-axis and a vertical y-axis and the origin at the right edge of the marble block. (What about the z-coordinate? We can use symmetry arguments in the same way as we did in Chapter 8 and find that the z-component of the center of mass is located in the plane that divides block and cylinder into halves.)

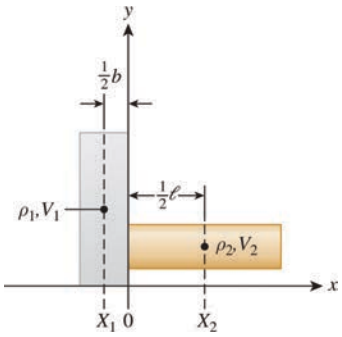


FIGURE 11.10 Sketch for calculating the center of mass of the sculpture.

RESEARCH

With the chosen coordinate system, we also do not need to worry about calculating the y-coordinate of the center of mass of the sculpture. The condition for stability depends only on whether the x-coordinate of the center of mass is within the marble block; it does not depend on how high the center of mass is off the ground. Thus, the only task left is to calculate the x-component of the center of mass. According to the general principles for calculating center-of-mass coordinates, developed in Chapter 8, we can write

$$X = \frac{1}{M}\int_V x\rho\left(\vec{r}\right)dV, \qquad \text{(i)}$$

where M is the mass of the entire sculpture and V is its volume. Note that in this case the mass density is not homogeneous, since the marble and the wood have different densities.

In order to perform the integration, we split the volume V into convenient parts: $V = V_1 + V_2$, where V_1 is the volume of the marble block and V_2 is the volume of the wooden cylinder. Then equation (i) becomes

$$\begin{aligned} X &= \frac{1}{M}\int_{V_1} xp\left(\vec{r}\right)dV + \frac{1}{M}\int_{V_2} x\rho\left(\vec{r}\right)dV \\ &= \frac{1}{M}\int_{V_1} x\rho_1 dV + \frac{1}{M}\int_{V_2} x\rho_2 dV. \end{aligned}$$

SIMPLIFY

To calculate the location of the x-component of the center of mass of the marble block alone, we can use the equation for constant density from Chapter 8:

$$X_1 = \frac{1}{M_1}\int_{V_1} x\rho_1 dV = \frac{\rho_1}{M_1}\int_{V_1} x dV.$$

(Since the density is constant over this entire volume, we can move it out of the integral.) In the same way, we can find the x-component of the center of mass of the wooden cylinder:

$$X_2 = \frac{\rho_2}{M_2} \int_{V_2} x dV.$$

Therefore, the expression for the center of mass of the composite object—that is, the entire sculpture—is

$$\begin{aligned} X &= \frac{\rho_1}{M} \int_{V_1} x dV + \frac{\rho_2}{M} \int_{V_2} x dV \\ &= \frac{M_1}{M} \frac{\rho_1}{M_1} \int_{V_1} x dV + \frac{M_2}{M} \frac{\rho_2}{M_2} \int_{V_2} x dV \qquad \text{(ii)} \\ &= \frac{M_1}{M} X_1 + \frac{M_2}{M} X_2. \end{aligned}$$

This is a very important general result: Even for extended objects, the combined center of mass can be calculated in the same way as it is for point particles. Since the total mass of the sculpture is the combined mass of its two parts, $M = M_1 + M_2$, equation (ii) becomes

$$X = \frac{M_1}{M_1 + M_2} X_1 + \frac{M_2}{M_1 + M_2} X_2. \qquad \text{(iii)}$$

It is important to note that this relationship between the coordinate of combined center of mass of a composite object and the individual center-of-mass coordinates is true even in the case where the parts are separate objects. Further, it holds in the case

when the density inside a given object is not constant. Formally, this result relies on the fact that a volume integral can always be split into a set of integrals over disjoint subvolumes that add up to the whole. That is, integration is linear, as it is merely addition.

Deriving equation (iii) has simplified a complicated problem greatly, because the center-of-mass coordinates of the two individual objects can be calculated easily. Since the density of each of them is constant, their center-of-mass locations are identical to their geometrical centers. One look at Figure 11.10 is enough to convince us that $X_2 = \frac{1}{2}\ell$ and $X_1 = -\frac{1}{2}b$. (Remember, we chose the origin of the coordinate system as the right edge of the marble block.)

All that is left now is to calculate the masses of the two objects. Since we know their densities, we only need to figure out each object's volume; then the mass is given by $M = \rho \mathrm{V}$.

Since the marble block is rectangular, its volume is $V = abc$. Thus, we have

$$M_1 = \rho_1 abc.$$

The horizontal wooden part is a cylinder, so its mass is

$$M_2 = \frac{\rho_2 l \pi d^2}{4}.$$

CALCULATE

Inserting the numbers given in the problem statement, we obtain for the individual masses

$$M_1 = (2850\ \mathrm{kg/m^3})(0.71\ \mathrm{m})(0.71\ \mathrm{m})(2.74\ \mathrm{m}) = 3936.52\ \mathrm{k}$$

$$M_2 = \frac{(440\ \mathrm{kg/m^3})(2.84\ \mathrm{m})\pi(0.71\ \mathrm{m})^2}{4} = 494.741\ \mathrm{kg}.$$

Thus, the combined mass is

$$M = M_1 + M_2 = 3936.52\ \mathrm{kg} + 494.741\ \mathrm{kg} = 4431.261\ \mathrm{kg}$$

The location of the x-component of the center of mass of the sculpture is then

$$X = \frac{3936.52\ \text{kg}}{4431.261\ \text{kg}}[(-0.5)(0.71\ \text{m})] + \frac{494.741\ \text{kg}}{4431.261\ \text{kg}}[(0.5)(2$$

ROUND

The densities were given to three significant figures, but the length dimensions were given to only two significant figures. Rounding thus results in

$$X = -0.16\ \text{m}.$$

Since this number is negative, the center of mass of the sculpture is located to the left of the right edge of the marble block. Thus, it is located above the base of the block and is supported from directly below. The sculpture is stable and can stand without bracing.

DOUBLE-CHECK

From Figure 11.9a, it seems hardly possible that this sculpture wouldn't tip over. However, our eyes can deceive us, as the density of the sculpture isn't constant. The ratio of the densities of the two materials used in the sculpture is $\rho_1/\rho_2 = (2850\ \text{kg/m}^3)/(440\ \text{kg/m}^3) = 6.48$. Therefore, we would obtain the same location for the center of mass if the 2.84-m-long cylinder made of wood were replaced by a cylinder of the same length made of marble, with its central axis located at the same place as that of the wooden cylinder, but thinner by a factor of $\sqrt{6.48} = 2.55$. The sculpture shown in Figure 11.11 has the same center-of-mass location as the sculpture in Figure 11.9a. Figure 11.11 should convince you that the sculpture is able to stand in stable equilibrium without bracing.

FIGURE 11.11
Sculpture made entirely of marble that has the same center-of-mass location as the marble-and-wood sculpture in Figure 11.9a.

Concept Check 11.1

In Solved Problem 11.1, the total mass of the sculpture was M, and the x-component of the sculpture's center of mass was found to be X. If a point mass, m_3, were placed at the far right end of the wooden cylinder $(X_3 = \ell)$, which of the following would express the criterion for the largest magnitude m_3 could have without making the sculpture unstable?

a) $\dfrac{M + m_3}{X + X_3} = \ell$

b) $\dfrac{MX + m_3X_3}{M - m_3} = \ell/2$

c) $\dfrac{M + m_3}{X + X_3} = 0$

d) $\dfrac{MX - m_3X_3}{M + m_3} = 0$

e) $\dfrac{MX - m_3X_3}{X - X_3} = 0$

The next example considers a situation in which the force of static friction plays an essential role. Static friction forces help maintain many arrangements of objects in equilibrium.

EXAMPLE 11.4 Person Standing on a ladder

Typically, a ladder stands on a horizontal surface (the floor) and leans against a vertical surface (the wall). Suppose a ladder of length $\ell = 3.04$ m, with mass $m_1 = 13.3$ kg, rests against a smooth wall at an angle of $\theta = 24.8^\circ$. A student, who has a mass of $m_m = 62.0$ kg, stands on the ladder (Figure 11.12a). The student is standing on a rung that is $r = 1.43$ m along the ladder, measured from where the ladder touches the ground.

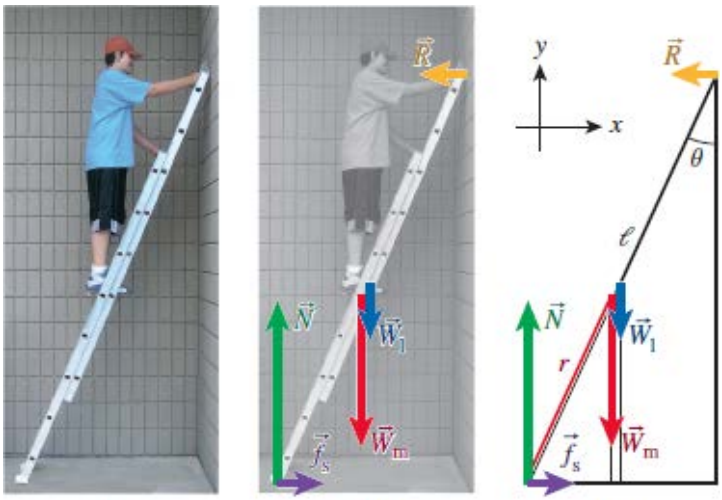

FIGURE 11.12 (a) Student standing on a ladder. (b) Force vectors superimposed. (c) Free-body diagram of the ladder.

a-b: W. Bauer and G. D. Westfall

PROBLEM 1

What friction force must act on the bottom of the ladder to keep it from slipping? Neglect the (small) force of friction between the smooth wall and the ladder.

SOLUTION 1

Let's start with the free-body diagram shown in Figure 11.12c. Here $\vec{R} = -R\hat{x}$ is the normal force exerted by the wall on the

ladder, $\overrightarrow{N} = N\hat{y}$ is the normal force exerted by the floor on the ladder, and $\overrightarrow{W}_m = -m_m g\hat{y}$ and $\overrightarrow{W}_1 = -m_1 g\hat{y}$ are the weights of the student and the ladder: $m_m g = (62.0\ \text{kg})\left(9.81\ \text{m/s}^2\right) = 608.\ \text{N}$ and $m_1 g = (13.3\ \text{kg})\left(9.81\ \text{m/s}^2\right) = 130.\ \text{N}$.

We'll let $\overrightarrow{f}_\text{s} = f_\text{s}\widehat{x}$ be the force of static friction between the floor and the bottom of the ladder, which is the answer to the problem. Note that this force vector is directed in the positive x-direction (if the ladder slips, its bottom will slide in the negative x-direction, and the friction force must necessarily oppose that motion). As instructed, we neglect the force of friction between wall and ladder.

The ladder and the student are in translational and rotational equilibrium, so we have the three equilibrium conditions introduced in equations 11.5 through 11.7:

$$\sum_i F_{x,i} = 0, \quad \sum_i F_{y,i} = 0, \quad \sum_i \tau_i = 0.$$

Let's start with the equation for the force components in the horizontal direction:

$$\sum_i F_{x,i} = f_\text{s} - R = 0 \Rightarrow R = f_\text{s}.$$

From this equation, we learn that the force the wall exerts on the ladder and the friction force between the ladder and the floor have the same magnitude. Next, we write the equation for the force components in the vertical direction:

$$\sum_i F_{y,i} = N - m_\text{m} g - m_1 g = 0 \Rightarrow N = g(m_\text{m} + m_1).$$

The normal force that the floor exerts on the ladder is exactly equal in magnitude to the sum of the weights of ladder and man: $N = 608.\text{N} + 130.\text{N} = 738.\text{N}$. (Again, we neglect the friction force between wall and ladder, which would otherwise have come in here.)

Now we sum the torques, assuming that the pivot point is where the ladder touches the ground. This assumption has the advantage of allowing us to ignore the forces acting at that point, because their moment arms are zero.

$$\sum_i \tau_i = (m_1 g)\left(\frac{\ell}{2}\right)\sin\theta + (m_\mathrm{m} g) r\,\sin\theta - Rl\cos\theta = 0$$

Note that the torque from the wall's normal force acts counterclockwise, whereas the two torques from the weights of the student and the ladder act clockwise. Also, the angle between the normal force, $\overrightarrow{R}$, and its moment arm, $\overrightarrow{\ell}$, is $90^\circ - \theta$, and $\sin(90^\circ - \theta) = \cos\theta$. Now we solve equation (i) for R:

$$R = \frac{\frac{1}{2}(m_1 g)\ell\,\sin\theta + (m_\mathrm{m} g) r\,\sin\theta}{l\cos\theta} = \left(\frac{1}{2}m_1 g + m_\mathrm{m} g\frac{r}{\ell}\right)\mathrm{t}$$

Numerically, we obtain

$$R = \left(\frac{1}{2}(130.\ \mathrm{N}) + (608.\ \mathrm{N})\frac{1.43\ \mathrm{m}}{3.04\ \mathrm{m}}\right)(\tan 24.8^\circ) = 162.\mathrm{N}$$

However, we already found that $R = f_\mathrm{s}$, so our answer is $f_\mathrm{s} = 162.\ \mathrm{N}$.

PROBLEM 2

Suppose that the coefficient of static friction between ladder and floor is 0.31. Will the ladder slip?

SOLUTION 2

We found the normal force in the first part of this example: $N = g(m_\mathrm{m} + m_1) = 738.\ \mathrm{N}$. It is related to the maximum static

friction force via $f_{\text{s,max}} = \mu_\text{s} N$. So, the maximum static friction force is 229. N, well above the 162. N that we just found necessary for static equilibrium. In other words, the ladder will not slip.

In general, the ladder will not slip as long as the force from the wall is smaller than the maximum force of static friction, leading to the condition

$$R = \left(\frac{1}{2}m_1 + m_\text{m}\frac{r}{\ell}\right) g\tan\theta \leq \mu_\text{s}(m_1 + m_\text{m})g. \quad \text{(ii)}$$

PROBLEM 3

In which direction does the force that the ground exerts on the ladder point?

SOLUTION 3

Figure 11.12 shows the horizontal $\left(\vec{f_s}\right)$ and vertical $\left(\vec{N}\right)$ components of the force that the ground exerts on the ladder. Calling the angle between this force and the ground ϕ, we have

$$\varphi = \tan^{-1}\left(\frac{F_y}{F_x}\right) = \tan^{-1}\left(\frac{N}{f_\text{s}}\right) = \tan^{-1}\left(\frac{738.}{162.}\right) = 77.6$$

The problem statement says that the ladder makes an angle of $24.8°$ with the wall. Therefore, it makes an angle of $90^\circ - 24.8^\circ = 65.2^\circ$ with the ground. Note that this is not the same as φ; the force exerted by the ground on a ladder in a situation like this does *not*, in general, point along the ladder!

PROBLEM 4

What happens as the student climbs higher on the ladder?

SOLUTION 4

From equation (ii), we see that R grows larger with increasing r. Eventually, this force will overcome the maximum force of static friction, and the ladder will slip. You can now understand why it is not a good idea to climb too high on a ladder in this kind of situation.

Concept Check 11.2

What can the student in Example 11.4 do if he really has to get up just a bit higher than the maximum height allowed by equation (ii) for the given situation?

a) He can increase the angle θ between the wall and the ladder.

b) He can decrease the angle θ between the wall and the ladder.

c) Neither increasing nor decreasing the angle will make any difference.

Concept Check 11.3

The absolute value of the force exerted on the ladder by the floor is given by

a) N.

b) f_s.

c) $N + f_s$.

d) $N - f_s$.

e) $\sqrt{N^2 + f_s^2}$.

SOLVED PROBLEM 11.2 Hanging a Storefront Sign

It is not uncommon for businesses to hang a sign over the sidewalk, suspended from a building's front wall. They often attach a post to the wall by a hinge and hold it horizontal by a cable that is also attached to the wall: the sign is then suspended from the post. Suppose the mass of the sign in Figure 11.13a is $M = 33.1$ kg, and the mass of the post is $m = 19.7$ kg. The length of the post is $l = 2.40$ m, and the sign is attached to the post as shown at a distance $r = 1.95$ m from the wall. The cable is attached to the wall a distance $d = 1.14$ m above the post.

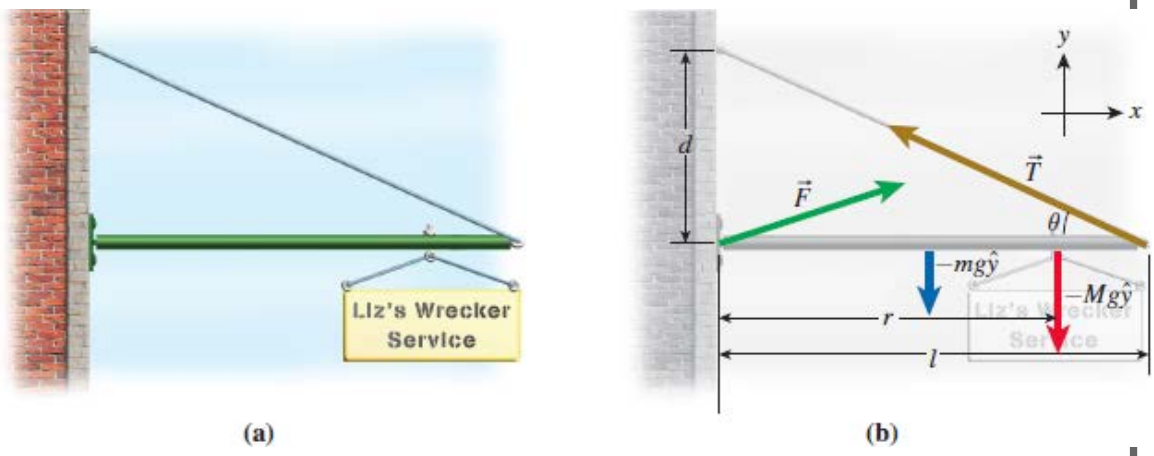

FIGURE 11.13 (a) Hanging storefront sign; (b) free-body diagram for the post.

PROBLEM

What is the tension in the cable holding the post? What is the magnitude and direction of the force, $\vec{F}$, that the wall exerts on the post?

SOLUTION

THINK

This problem involves static equilibrium, moment arms, and torques. Static equilibrium means vanishing net external force and torque. In order to determine the torques, we have to pick a pivot point. It seems natural to pick the point where the hinge attaches the post to the wall. Because a hinge is used, the post can rotate about this point. Picking this point also has the advantage that we do not need to pay attention to the force that the wall exerts on the post, because that force will act at the contact point (the hinge) and thus have a moment arm of zero and consequently make no contribution to the torque.

SKETCH

To calculate the net torque, we start with a free-body diagram that shows all the forces acting on the post (Figure 11.13b). We know that the weight of the sign (red arrow) acts at the point where the sign is suspended from the post. The gravitational force acting on the post is represented by the blue arrow, which points downward from the center of mass of the post. Finally, we know that the tension, $\overrightarrow{T}$ (yellow arrow), is acting along the direction of the cable.

RESEARCH

The angle θ between the cable and the post (see Figure 11.13b) can be found from the given data:

$$\theta = \tan^{-1}\left(\frac{d}{l}\right).$$

The equation for the torques about the point where the post touches the wall is then

$$mg\frac{l}{2}\sin 90^\circ + Mgr\sin 90^\circ - Tl\sin\theta = 0. \qquad \text{(i)}$$

Figure 11.13b also shows a green arrow for the force, $\overrightarrow{F}$, that the wall exerts on the post, but the direction and magnitude of this force vector are still to be determined. Equation (i) cannot be

used to find this force, because the point where this force acts is the pivot point, and thus the corresponding moment arm has length zero.

On the other hand, once we have found the tension in the cable, we will have determined all the other forces involved in the problem situation, and we know from the condition of static equilibrium that the net force has to be zero. We can thus write separate equations for the horizontal and vertical force components. In the horizontal direction, we have only two force components, from the tension and the force from the wall:

$$F_x - T\cos\theta = 0 \Rightarrow F_x = T\cos\theta.$$

In the vertical direction, we have the weights of the beam and the sign, in addition to the vertical components of the tension and the force from the wall:

$$F_y + T\sin\theta - mg - Mg = 0 \Rightarrow F_y = (m+M)g - T\sin\theta.$$

SIMPLIFY

We solve equation (i) for the tension:

$$T = \frac{(ml + 2Mr)g}{2l\sin\theta}. \qquad \text{(ii)}$$

For the magnitude of the force that the wall exerts on the post, we find

$$F = \sqrt{F_x^2 + F_y^2}.$$

The direction of this force is given by

$$\theta_F = \tan^{-1}\left(\frac{F_y}{F_x}\right).$$

CALCULATE

Inserting the numbers given in the problem statement, we find the angle θ:

$$\theta = \tan^{-1}\left(\frac{1.14\ \text{m}}{2.40\ \text{m}}\right) = 25.4077^\circ.$$

We obtain the tension in the cable from equation (ii):

$$T = \frac{[(19.7\ \text{kg})(2.40\ \text{m}) + 2(33.1\ \text{kg})(1.95\ \text{m})]\left(9.81\ \text{m/s}^2\right)}{2(2.40\ \text{m})(\sin 25.4077^\circ)}$$

The magnitudes of the components of the force that the wall exerts on the post are

$$F_x = (840.113\ \text{N})(\cos 25.4077^\circ) = 758.855\ \text{N}$$
$$F_y = (19.7\ \text{kg} + 33.1\ \text{kg})\left(9.81\ \text{m/s}^2\right) - (840.113\ \text{N})(\sin 2$$

Therefore, the magnitude and direction of that force are given by

$$F = \sqrt{(157.512\ \text{N})^2 + (758.855\ \text{N})^2} = 775.030\ \text{N}$$
$$\theta_F = \tan^{-1}\left(\frac{157.512}{785.855}\right) = 11.726^\circ.$$

ROUND

All of the given quantities were specified to three significant figures, and so we round our final answers to three digits: $T = 840.\ \text{N}$, $F = 775.\ \text{N}$, and $\theta_F = 11.7^\circ$.

DOUBLE-CHECK

The two forces that we calculated have rather large magnitudes, considering that the combined weight of the post and attached sign is only

$$F_g = (m + \mathrm{M})g = (19.7\ \mathrm{kg} + 33.1\ \mathrm{kg})\left(9.81\ \mathrm{m/s^2}\right) = 518.$$

In fact, the sum of the magnitudes of the force from the cable on the post, T, and the force from the wall on the post, F, is larger than the combined weight of the post and the sign by more than a factor of 3. Does this make sense? Yes, because the two force vectors, $\overrightarrow{T}$ and $\overrightarrow{F}$, have rather large horizontal components that have to cancel each other. When we calculate the magnitudes of these forces, their horizontal components are also included. As the angle θ between the cable and the post approaches zero, the horizontal components of $\overrightarrow{T}$ and $\overrightarrow{F}$ become larger and larger. Thus, you can see that selecting a distance d in Figure 11.13b that is too small relative to the length of the post will result in a huge tension in the cable and a very stressed suspension system.

Concept Check 11.4

If all other parameters in Solved Problem 11.2 remain unchanged, but the sign is moved farther away from the wall, toward the end of the post, what happens to the tension, T?

a) It decreases.

b) It stays the same.

c) It increases.

Concept Check 11.5

If all other parameters in Solved Problem 11.2 remain unchanged, but the angle θ between the cable and the post is increased, what happens to the tension, T?

a) It decreases.

b) It stays the same.

c) It increases.

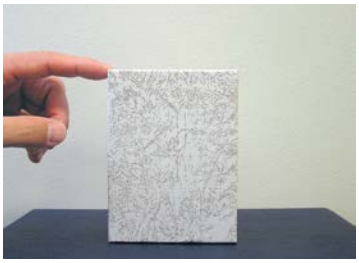
11.3 Stability of Structures

For a skyscraper or a bridge, designers and builders need to worry about the ability of the structure to remain standing under the influence of external forces. For example, after standing for 40 years, the bridge carrying Interstate 35W across the Mississippi River in Minneapolis, shown in Figure 11.14, collapsed on August 1, 2007, probably from design-related causes. This bridge collapse and other architectural disasters are painful reminders that the stability of structures is a paramount concern.

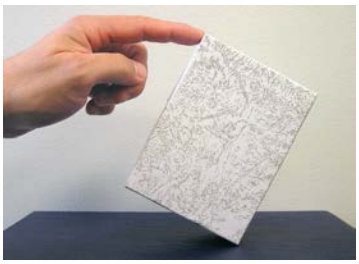
FIGURE 11.14 The bridge carrying Interstate 35W across the Mississippi River in Minneapolis collapsed on August 1, 2007, during rush hour.

Scott Olson/Getty Images

Let’s try to quantify the concept of stability by looking at Figure 11.15a, which shows a box in static equilibrium, resting on a horizontal surface. Our experience tells us that if we use a finger to push with a small force in the way shown in the figure, the box remains in the same position. The small force we exert on the box is exactly balanced by the force of friction between the box and the supporting surface. The net force is zero, and there is no motion. If we steadily increase the magnitude of the force we apply, there are two possible outcomes: If the friction force is not sufficient to counterbalance the force exerted by the finger, the box begins to slide to the right. Or, if the torque due to the weight of the box acting at its center of gravity is less than the torque due the applied force and the friction force, the box starts to tilt as shown in Figure 11.15b. Thus, the static equilibrium of the box is stable with respect to small external forces, but a sufficiently large external force destroys the equilibrium.



(a)



(b)

FIGURE 11.15 (a) Pushing with a small force against the upper edge of a box. (b) Exerting a larger force on the box results in tilting it.

a-b: W. Bauer and G. D. Westfall

This simple example illustrates the characteristic of **stability.** Engineers need to be able to calculate the maximum external forces and torques that can be present without undermining the stability of a structure.

Quantitative Condition for Stability

In order to be able to quantify the stability of an equilibrium situation, we start with the relationship between potential energy and force in one dimension from Chapter 6:

$$F_x(x) = -\frac{dU(x)}{dx}.$$

In three dimensions, this is

$$\vec{F}\left(\vec{r}\right) = -\vec{\nabla}U\left(\vec{r}\right),$$

where $\vec{\nabla}U\left(\vec{r}\right) = \left(\frac{\partial U\left(\vec{r}\right)}{\partial x}\hat{x} + \frac{\partial U\left(\vec{r}\right)}{\partial y}\hat{y} + \frac{\partial U\left(\vec{r}\right)}{\partial z}\hat{z} \right)$ is the first gradient derivative of the potential energy function with respect to the position vector. A vanishing net force is one of the equilibrium conditions, which we can write as $\frac{dU(x)}{dx} = 0$ in one dimension or $\vec{\nabla}U\left(\vec{r}\right) = 0$ in three dimensions, at a given point in space. So far, the condition of vanishing first derivative adds no new insight. However, we can use the second derivative of the potential energy function to distinguish three different cases, depending on the sign of the second derivative.

Case 1 Stable Equilibrium

$$\text{Stable equilibrium: } \left.\frac{d^2U(x)}{dx^2}\right|_{x=x_0} > 0. \qquad \textbf{(11.8)}$$

If the second derivative of the potential energy function with respect to the coordinate is positive at a point, then the potential energy has a local minimum at that point. The system is in **stable equilibrium.** In this case, a small deviation from the equilibrium position creates a restoring force that drives the system back to the equilibrium point. This situation is illustrated in Figure 11.16a: If the red dot is moved away from its equilibrium position at x_0 in either the positive or the negative direction and released, it will return to the equilibrium position.

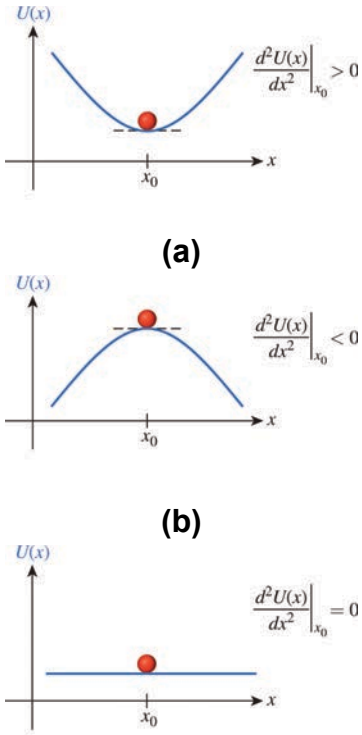


FIGURE 11.16 Local shape of the potential energy function at an equilibrium point: (a) stable equilibrium; (b) unstable equilibrium; (c) neutral equilibrium.

Case 2 Unstable Equilibrium

$$\text{Untable equilibrium: } \left.\frac{d^2U(x)}{dx^2}\right|_{x=x_0} < 0. \qquad \textbf{(11.9)}$$

If the second derivative of the potential energy function with respect to the coordinate is negative at a point, then the potential energy has a local maximum at that point. The system is in **unstable equilibrium.** In this case, a small deviation from the equilibrium position creates a force that drives the system away from the equilibrium point. This situation is illustrated in Figure 11.16b: If the red dot is moved even slightly away from its equilibrium position at x_0 in either the positive or the negative direction and released, it will move away from the equilibrium position.

Case 3 Neutral Equilibrium

$$\text{Neutral equilibrium: } \left.\frac{d^2U(x)}{dx^2}\right|_{x=x_0} = 0. \qquad \textbf{(11.10)}$$

The case in which the sign of the second derivative of the potential energy function with respect to the coordinate is neither positive nor negative at a point is called **neutral equilibrium,** also referred to as *indifferent* or *marginally stable*. This situation is illustrated in Figure 11.16c: If the red dot is displaced by a small amount, it will neither return to nor move away from its original equilibrium position. Instead, it will simply stay in the new position, which is also an equilibrium position.

Multidimensional Surfaces and Saddle Points

The three cases just discussed cover all possible types of stability for one-dimensional systems. They can be generalized to two- and three-dimensional potential energy functions that depend on more than one coordinate. Instead of looking at only the derivative with respect to one coordinate, as in equations 11.8 through 11.10, we have to examine all partial derivatives. For the two-dimensional potential energy function $U(x,y)$, the equilibrium condition is that the first derivative with respect to each of the two coordinates is zero. In addition, stable equilibrium requires that at the point of equilibrium the second derivative of the potential energy function is positive for both coordinates, whereas unstable equilibrium implies that it is negative for both, and neutral equilibrium means that it is zero for both. Parts (a) through (c) of Figure 11.17 show these three cases, respectively.

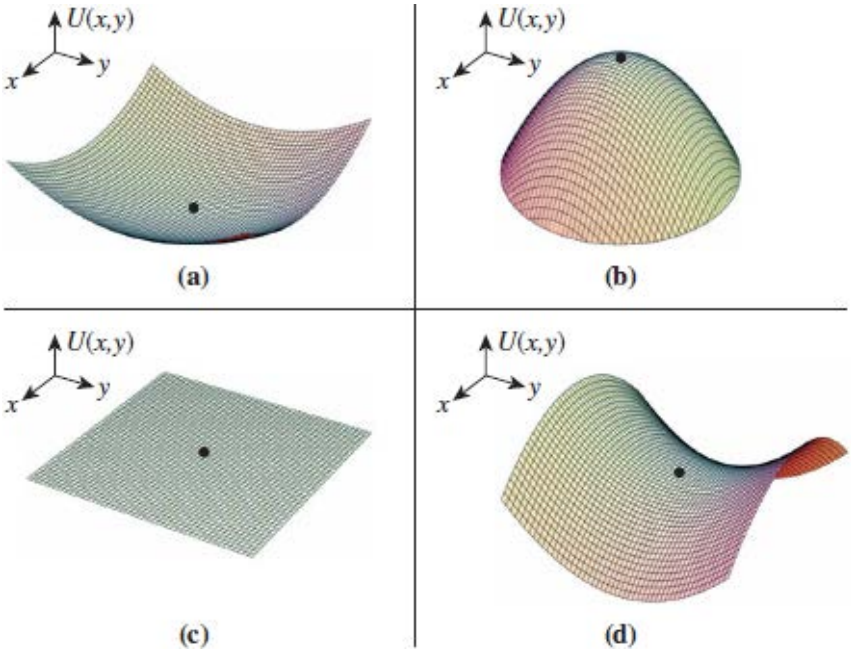

FIGURE 11.17 Different types of equilibrium for a three-dimensional potential energy function.

However, in more than one spatial dimension, the possibility also exists that at one equilibrium point the second derivative with respect to one coordinate is positive, whereas it is negative for the other coordinate. These points are called *saddle points,* because the

potential energy function is locally shaped like a saddle. Figure 11.17d shows such a saddle point, where one of the second partial derivatives is negative and one is positive. The equilibrium at this saddle point is stable with respect to small displacements in the y-direction, but unstable with respect to small displacements in the x-direction.

In a strict mathematical sense, the conditions noted above for the second derivative are sufficient for the existence of maxima and minima, but not necessary. Sometimes, the first derivative of the potential energy function is not continuous, but extrema can still exist, as the following example shows.

Concept Check 11.6

In Figure 11.17, which surface—(a), (b), (c), or (d)—contains equilibrium points other than the one marked with the black dot?

EXAMPLE 11.5 Pushing a Box

PROBLEM 1

What is the force required to hold the box in Figure 11.15 in equilibrium at a given tilt angle?

SOLUTION 1

Before the finger pushes on the box, the box is resting on a level surface. The only two forces acting on it are the force of gravity and a balancing normal force. There is no net force and no net torque; the box is in equilibrium (Figure 11.18a).

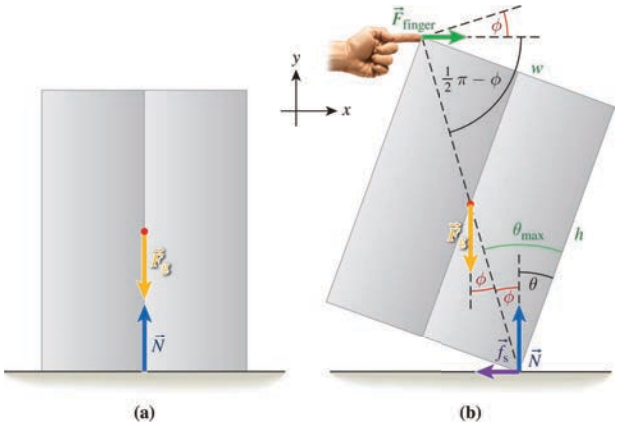

FIGURE 11.18 Free-body diagrams for the box (a) resting on the level surface and (b) being tilted by a finger pushing in the horizontal direction.

Once the finger starts pushing in the horizontal direction at the very top of the box's left side and the box starts tilting, the normal force vector acts at the contact point (Figure 11.18b). The force of static friction acts at the same point but in the horizontal direction. Since the box does not slip, the friction force vector has exactly the same magnitude as the external force vector due to the pushing by the finger, but acts in the opposite direction.

We can now calculate the torques due to these forces and find the condition for equilibrium, that is, how much force it takes for the finger to hold the box at an angle θ with respect to the vertical. Figure 11.18b also indicates the angle θ_{max}, which is a geometric property of the box that can be calculated from the ratio of the width w and the height h: $\theta_{\text{max}} = \tan^{-1}(w/h)$. Of crucial importance is the angle $\boldsymbol{\phi}$, which is the difference between these two angles (see Figure 11.18b): $\phi = \theta_{\text{max}} - \theta$. The angle $\boldsymbol{\phi}$ decreases with increasing θ until $\theta = \theta_{\text{max}} \Rightarrow \phi = 0$, at which time the box falls over into the horizontal position.

Using equation 11.7, we can calculate the net torque. The natural pivot point in this situation is the contact point between the box and the support surface. The friction force and the normal force then have moment arms of zero length and thus do not contribute to the net torque. The only clockwise torque is due to the force from the finger, and the only counterclockwise torque results from the force of gravity. The length of the moment arm for the force from the finger is (see Figure 11.18b) $\ell = \sqrt{h^2 + w^2}$, and the length of the moment arm for the force of gravity is half of this value, or $\ell/2$. This means that equation 11.7 becomes

$$(F_{\text{g}})\left(\tfrac{1}{2}\ell\right)\sin\phi - (F_{\text{finger}})(\ell)\sin\left(\tfrac{1}{2}\pi - \phi\right) = 0.$$

We can use $\sin\left(\frac{1}{2}\pi - \phi\right) = \cos\,\phi$ and $F_g = mg$ and then solve for the force the finger must provide to keep the box at equilibrium at a given angle:

$$F_{\text{finger}}(\theta) = \tfrac{1}{2}mg\,\tan\left[\tan^{-1}\left(\frac{w}{h}\right) - \theta\right]. \qquad \text{(i)}$$

Figure 11.19 shows a plot of the force from the finger that is needed to hold the box at equilibrium at a given angle, from equation (i), for different ratios of box width to height. The curves reflect values of the angle θ between zero and θ_{max}, which is the point where the force required from the finger is zero, and where the box tips over.

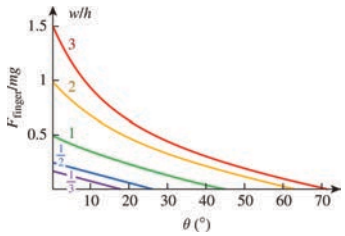

FIGURE 11.19
Ratio of the force of the finger to the weight of the box needed to hold the box in equilibrium as a function of the angle, plotted for different representative values of the ratio of the width to the height of the box.

PROBLEM 2

Determine the potential energy function for this box.

SOLUTION 2

Finding the solution to this part of the example is much more straightforward than for the first part. The potential energy is the gravitational potential energy, $U = mgy$, where y is the vertical coordinate of the center of mass of the box. Looking at Figure 11.18b we can see that $\cos\phi = \dfrac{y}{\sqrt{(w/2)^2 + (h/2)^2}}$.

Remembering that $\phi = \theta_{\max} - \theta$ we can write the potential energy as a function of θ as

$$U = mgy = mg\sqrt{(w/h)^2 + (h/2)^2}\cos(\theta_{\max} - \theta) = mg\sqrt{(}$$

Figure 11.20, shows (red curve) the location of the center of mass of the box for different tipping angles. The curve traces out a

segment of a circle with center at the lower right corner of the box. The dashed red line shows the same curve, but for angles $\theta > \theta_{\max}$, for which the box tips over into the horizontal position without the finger exerting a force on it. You can clearly see that this potential energy function has a maximum at the point where the box stands on edge and its center of mass is exactly above the contact point with the surface. The curve for the location of the center of mass when the box is tilted to the left is shown in blue in Figure 11.20. You can see that the potential energy function has a minimum when the box rests flat on the table. *Note:* At this equilibrium point, the first derivative does not exist in the mathematical sense, but it is apparent from the figure that the function has a minimum, which is sufficient for stable equilibrium.

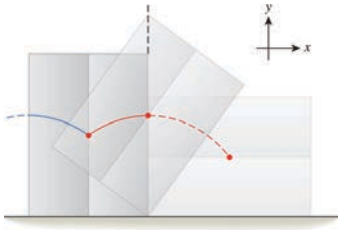

FIGURE 11.20
Location of the center of mass of the box as a function of tipping angle.

Self-Test Opportunity 11.4

What is the minimum value that the coefficient of static friction can have if the box in Example 11.5 is to tip over and the ratio of the width to the height of the box is 0.4?

SOLVED PROBLEM 11.3 Standing on a Board

PROBLEM

Persons A and B are standing on a board of uniform linear density that is balanced on two supports, as shown in Figure 11.21. What are the minimum and maximum distances x from the left end of the board at which person A can stand without tipping the board? Treat the people as point masses. The mass of person A is 1.35 times that of person B, and the mass of the board is 0.29 times that of person B.

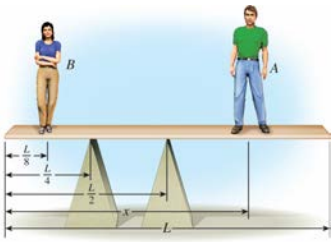

FIGURE 11.21 Two people on a board.

SOLUTION

THINK

This problem asks for the range of values for the position x of person A. If he moves too far to the right, the board may tip in the clockwise direction, and if he moves too far to the left, it may tip in the counterclockwise direction. When tipping in the clockwise direction, the board will pivot about the tip of the right support; and when tipping in the counterclockwise direction, the board will pivot about the tip of the left support. Selecting these two points for the limiting cases of maximum and minimum values of x will make our solution much easier.

SKETCH

The sketch in Figure 11.22 consists of a coordinate axis, for which we chose the location of the origin at the left end of the board. The individual centers of mass of person A (with mass m_A), person B (with mass m_B), and the board (with mass m_C) are

indicated with red dots on the coordinate axis. The location of the combined center of mass of all three is shown with a blue dot. As long as this blue dot resides between $L/4$ and $L/2$, the locations of the two supports, the overall arrangement of the two persons on the board is stable.

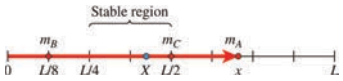

FIGURE 11.22
Coordinate axis showing the location of the combined center of mass for the two people on the board.

RESEARCH

The coordinate of the combined center of mass is given by

$$X = \frac{m_A x + m_B L/8 + m_C L/2}{m_A + m_B + m_C}.$$

Here we have used the fact that person B is located at $L/8$, as specified in Figure 11.21, and that the center of mass of the board is in its middle, at $L/2$. The location x of person A is to be determined. The minimum value of x is obtained when the center-of-mass coordinate is at the left support, $X(x_{\min}) = L/4$. and the maximum value of x is obtained when the center-of-mass coordinate is at the right support, $X(x_{\max}) = L/2$.

SIMPLIFY

The masses are given in terms of $m_B : m_A = 1.35\ m_B$ and $m_C = 0.29\ m_B$. We thus find for the combined center of mass:

$$X = \frac{1.35x + L/8 + 0.29L/2}{1.35 + 1 + 0.29} \Rightarrow$$
$$x = \frac{2.64}{1.35}X - \frac{1/8 + 0.29/2}{1.35}L.$$

We can then express x_{min} as

$$x_{\text{min}} = \frac{2.64}{1.35}\left(\frac{L}{4}\right) - \frac{1/8 + 0.29/2}{1.35}L$$

and x_{max} as

$$x_{\text{max}} = \frac{2.64}{1.35}\left(\frac{L}{2}\right) - \frac{1/8 + 0.29/2}{1.35}L.$$

CALCULATE

The expressions for x_{min} and x_{max} can be simplified to yield $x_{\text{min}} = 0.288889\ L$ and $x_{\text{max}} = 0.777778\ L$.

ROUND

The relative mass of the board was specified to two significant digits, and so we round our answers to the same precision: $x_{\text{min}} = 0.29\ L$ and $x_{\text{max}} = 0.78\ L$.

DOUBLE-CHECK

The answers are fractions of the length of the board, which means they pass the minimum test of dimensional analysis. We also expect the numerical coefficients to be between 0 and 1, and our answers pass this second test as well.

Concept Check **11.7**

If the two people in Solved Problem 11.3 traded places, so that person *A* was standing at $L/8$, how would the region of stability for person *B* change relative to what it was in Solved Problem 11.3?

a) It would be wider.

b) It would be narrower.

c) It would be the same.

Dynamic Adjustments for Stability

How does the mass damper in the Taipei 101 tower provide stability to the structure? To answer this question, let's first look at how human beings stand up straight. When you stand up straight, your center of mass is located directly above your feet. The gravitational force then exerts no net torque on you, and you can remain standing up straight. If other forces act on you (a strong wind blowing, for example, or a load you have to lift) and provide additional torques, your brain senses this through nerves coupled to the fluid in your inner ears and provides corrective action through slight shifts in the body's mass distribution. You can get a demonstration of your brain's impressive ability to make these dynamic stability adjustments by holding out your backpack (loaded with books, laptop computer, etc.) with outstretched arms in front of your body. This action will not cause you to fall over. However, if you stand straight against a wall, with your heels touching the base of the wall, the same attempt to hold your backpack with your arms outstretched will cause you to fall forward. Why? Because the wall behind you prevents your brain from shifting your body's mass distribution in order to compensate for the torque due to the backpack's weight.

Another way to gain a practical understanding of dynamic stability control is to balance an object like a hockey stick or a golf club with its handle end resting on the palm of your hand. You can accomplish this task with a little practice, in which you train your brain to tell the muscles in your arm to perform small corrective actions that counter the tilting motion of the object you are balancing. The same principles of dynamic stability adjustment are incorporated into the Segway Personal Transporter (Figure 11.23), an innovative system on two wheels, which is electric-powered and can reach speeds of up to 12 mph. Just like your brain, the Segway senses its orientation relative to the vertical. But it uses gyroscopes instead of the fluid in the inner ear. And just like the brain, it counterbalances a net torque by providing a compensating torque in the opposite direction. The Segway accomplishes this by slightly turning its wheels in a clockwise or counterclockwise direction.

FIGURE 11.23 The Segway Personal Transporter provides dynamic stability adjustments.

Alexander Oganezov/Shutterstock

Finally, the mass damper at the top of the Taipei 101 tower is used in a similar way, to provide a subtle shift in the building's mass distribution, thus contributing to stability in the presence of net external torques due to the forces of strong winds. But it also dampens the oscillation of the building due to these forces, a topic we will return to in Chapter 14.

WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- Static equilibrium is mechanical equilibrium for the special case where the object in equilibrium is at rest.
- An object (or a collection of objects) can be in static equilibrium only if the net external force is zero and the net external torque is zero:

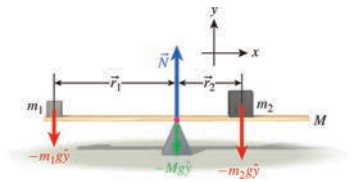
$$\vec{F}_{\text{net}} = \sum_{i=1}^{n} \vec{F}_i = \vec{F}_1 + \vec{F}_2 + \cdots + \vec{F}_n = 0$$

$$\vec{\tau}_{\text{net}} = \sum_{i} \vec{\tau}_i = 0$$

- The condition for static equilibrium can also be expressed as $\vec{\nabla} U\left(\vec{r}\right)\Big|_{\vec{r}_0} = 0$; that is, the first gradient derivative of the potential energy function with respect to the position vector is zero at the equilibrium point.
- The condition for stable equilibrium is that the potential energy function has a minimum at that point. A sufficient condition for stability is that the second derivative of the potential function with respect to the coordinate at the equilibrium point is positive.
- The condition for unstable equilibrium is that the potential energy function has a maximum at that point. A sufficient condition for instability is that the second derivative of the potential function with respect to the coordinate at the equilibrium point is negative.
- If the second derivative of the potential energy function with respect to the coordinate is zero at the equilibrium point, the equilibrium is neutral (or indifferent or marginally stable).

ANSWERS TO SELF-TEST OPPORTUNITIES

11.1 Choose the pivot point to be at the location of m_2.



$$F_{\text{net},y} = \sum_i F_{i,y} = -m_1 g - m_2 g - Mg + N = 0$$

$$\Rightarrow N = g(m_1 + m_2 + M) = m_1 g + m_2 g + Mg$$

$$\tau_{\text{net}} = \sum_i \tau_{\text{counterclockwise},i} - \sum_j \tau_{\text{clockwise},j}$$

$$\begin{aligned}
&\tau_{\text{net}} = m_1 g(r_1 + r_2)\sin 90^\circ + Mgr_2 \sin 90^\circ - Nr_2 \sin 90^\circ = 0 \\
&Nr_2 = m_1 g r_1 + m_1 g r_2 + Mgr_2 \\
&(m_1 g + m_2 g + Mg)r_2 = m_1 g r_2 + m_2 g r_2 + Mgr_2 = m_1 g r_1 + \\
&\cancel{m_1 g r_2} + m_2 g r_2 + \cancel{Mgr_2} = m_1 g r_1 + \cancel{m_1 g r_2} + \cancel{Mgr_2} \\
&m_2 \cancel{gr}_2 = m_1 \cancel{gr}_1 \\
&m_2 r_2 = m_1 r_1.
\end{aligned}$$

11.2 The biceps still has a nonzero moment arm even when the arm is fully extended, because the tendon has to wrap around the elbow joint and is thus never parallel to the radius bone.

11.3 The stack would be $(10{,}000)(4\text{ cm}) = 400\text{ m}$ high, comparable to the tallest skyscrapers. And the top block's right edge would stick out by

$$\tfrac{1}{2}(15\text{ cm})\sum_{i=1}^{10,000}\frac{1}{i} = \tfrac{1}{2}(15\text{ cm})(9.78761) = 73.4\text{ cm}.$$

11.4 From Figure 11.19, we can see that the force required is greatest at the beginning, for $\theta = 0$. If we set $\theta = 0$ in equation (i) of Example 11.5, we find the initial force that the finger needs to apply to displace the box from equilibrium:

$$F_{\text{finger}}(0) = \tfrac{1}{2}mg\tan\left[\tan^{-1}\left(\frac{w}{h}\right) - 0\right] = \tfrac{1}{2}mg\left(\frac{w}{h}\right).$$

A friction coefficient of at least $\mu_s = \frac{1}{2}(w/h)$ is needed to provide the matching friction force that prevents the box from sliding along the supporting surface: $\mu_s = \frac{1}{2}(0.4) = 0.2$.

PROBLEM-SOLVING GUIDELINES: STATIC EQUILIBRIUM

1. Almost all static equilibrium problems involve summing forces in the coordinate directions, summing torques, and setting the sums equal to zero. However, the right choices of coordinate axes and a pivot point for the torques can make the difference between a hard solution and an easy one. Generally, choosing a pivot point that eliminates the moment arm for an unknown force (and often more than one force!) will simplify the equations so that you can solve for some force components.

2. The key step in writing correct equations for situations of static equilibrium is to draw a correct free-body diagram. Be careful about the locations where forces act; because torques are involved, you must represent objects as extended bodies, not point particles, and the point of application of a force makes a difference. Check each force to make sure that it is exerted *on* the object in equilibrium and not *by* the object.

MULTIPLE-CHOICE QUESTIONS

11.1 A 3.00-kg broom is leaning against a coffee table. A woman lifts the broom handle with her arm fully stretched so that her hand is a distance of 0.450 m from her shoulder. What torque is produced on her shoulder by the broom if her arm is at an angle of 50.0° below the horizontal?

a) 7.00 N m

b) 5.80 N m

c) 8.51 N m

d) 10.1 N m

11.2 A uniform beam of mass M and length L is held in static equilibrium, and so the magnitude of the net torque about its center of mass is zero. The magnitude of the net torque on this beam about one of its ends, a distance of $L/2$ from the center of mass, is

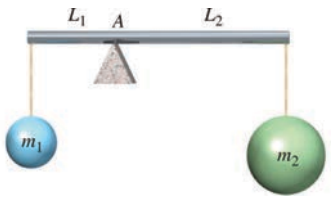
a) MgL

b) $mgL/2$

c) zero

d) $2MgL$

11.3 A very light and rigid rod is pivoted at point A and weights m_1 and m_2 are hanging from it, as shown in the figure. The ratio of the weight of m_1 to that of m_2 is 1:2. What is the ratio of L_1 to L_2, the distances from the pivot point to m_1 and m_2, respectively?



a) 1:2

b) 2:1

c) 1:1

d) not given enough information to determine

11.4 Which of the following are in static equilibrium?

a) a pendulum at the top of its swing

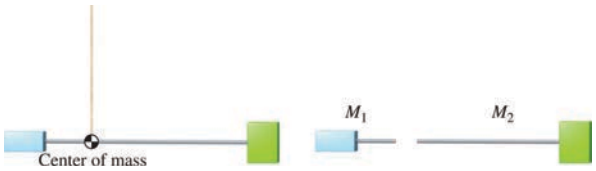
b) a merry-go-round spinning at constant angular velocity

c) a projectile at the top of its trajectory (with zero velocity)

d) all of the above

e) none of the above

11.5 The object in the figure below is suspended at its center of mass —thus, it is balanced. If the object is cut in two pieces at its center of mass, what is the relation between the two resulting masses?



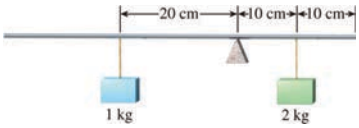
a) The masses are equal.

b) M_1 is less than M_2.

c) M_2 is less than M_1.

d) It is impossible to tell.

11.6 As shown in the figure, two weights are hanging on a uniform wooden bar that is 60 cm long and has a mass of 100 g. Is this system in equilibrium?



a) yes

b) no

c) cannot be determined

d) depends on the value of the normal force

11.7 A 15-kg child sits on a playground seesaw, 2.0 m from the pivot. A second child located 1.0 m on the other side of the pivot would have to have a mass _____ to lift the first child off the ground.

a) greater than 30 kg

b) less than 30 kg

c) equal to 30 kg

11.8 A mobile is constructed from a metal bar and two wooden blocks, as shown in the figure. The metal bar has a mass of 1.0 kg and is 10. cm long. The metal bar has a 3.0-kg wooden block hanging from the left end and a string tied to it at a distance of 3.0 cm from the left end. What mass should the wooden block hanging from the right end of the bar have to keep the bar level?

a) 0.70 kg

b) 0.80 kg

c) 0.90 kg

d) 1.0 kg

e) 1.3 kg

f) 3.0 kg

g) 7.0 kg

11.9 If a point mass were placed at the right end of the wooden cylinder in the sculpture in Figure 11.9a, how large could this mass be without the sculpture tipping over?

a) 2.4 kg

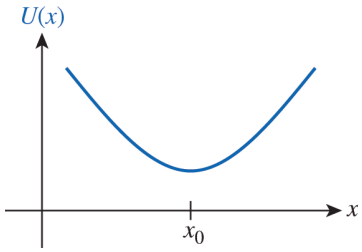
b) 29.1 kg

c) 37.5 kg

d) 245 kg

e) 1210 kg

11.10 Concerning the function $U(x)$ shown in the figure, which one of the following statements is true at $x = x_0$?



a) The first derivative with respect to x is zero, and the second derivative is positive.

b) The first derivative with respect to x is positive, and second derivative is zero.

c) The first derivative with respect to x is zero, and the second derivative is negative.

d) The first derivative with respect to x is negative, and the second derivative is zero.

e) Both the first derivative and the second derivative with respect to x are zero.

11.11 Which one of the following statements correctly expresses the requirement(s) for a system to be in static equilibrium?

a) The center of mass of the system must be at rest, but the system can be rotating.

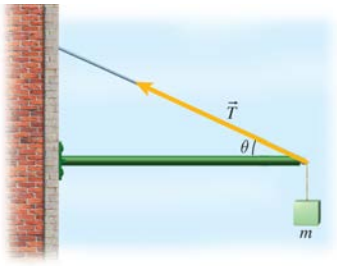
b) The center of mass of the system must be at rest or moving with a constant speed.

c) The center of mass of the system must be at rest, and the system must not be rotating.

d) The system must be rotating about its center of mass.

e) The system must be rotating at a constant angular speed around its center of mass, which is at rest.

11.12 In the figure, a cable supports a mass m, and a massless bar makes an angle θ with the horizontal. The bar is hinged to the wall. Which one of the following statements is correct?



a) As θ approaches zero, the tension $\overrightarrow{T}$ in the cable approaches zero.

b) As θ approaches 90°, the tension $\overrightarrow{T}$ in the cable approaches zero.

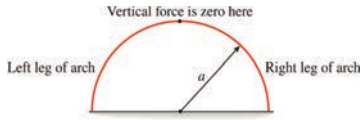
c) As θ approaches zero, the tension $\overrightarrow{T}$ in the cable approaches mg.

d) As θ approaches 90°, the tension $\overrightarrow{T}$ in the cable approaches mg.

CONCEPTUAL QUESTIONS

11.13 There are three sets of landing gear on an airplane: One main set is located under the centerline of each wing, and the third set is located beneath the nose of the plane. Each set of main landing gear has four tires, and the nose landing gear has two tires. If the load on each of the tires is the same when the plane is at rest, find the center of mass of the plane. Express your result as a fraction of the perpendicular distance between the centerline of the plane's wings to the plane's nose gear. (Assume that the landing gear struts are vertical when the plane is at rest and the dimensions of the landing gear are negligible compared to the dimensions of the plane.)

11.14 A semicircular arch of radius a stands on level ground as shown in the figure. The arch is uniform in cross section and density, with total weight W. By symmetry, at the top of the arch, each of the two legs exerts only horizontal forces on the other; ideally, the stress at that point is uniform compression over the cross section of the arch. What are the vertical and horizontal force components which must be supplied at the base of each leg to support the arch?



11.15 In the absence of any symmetry or other constraints on the forces involved, how many unknown force components can be determined in a situation of static equilibrium in each of the following cases?

a) All forces and objects lie in a plane.

b) Forces and objects are in three dimensions.

c) Forces act in n spatial dimensions.

11.16 You have a meter stick that balances at the 55-cm mark. Is your meter stick homogeneous?

11.17 You have a meter stick that balances at the 50-cm mark. Is it possible for your meter stick to be inhomogeneous?

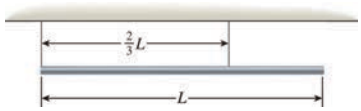
11.18 Why does a helicopter with a single main rotor generally have a second small rotor on its tail?

11.19 The system shown in the figure consists of a uniform (homogeneous) rectangular board that is resting on two identical rotating cylinders. The two cylinders rotate in opposite directions at equal angular velocities. Initially, the board is placed perfectly symmetrically relative to the center point between the two cylinders. Is this an equilibrium position for the board? If yes, is it in stable or unstable equilibrium? What happens if the board is given a very slight displacement out of the initial position?

11.20 If the wind is blowing strongly from the east, stable equilibrium for an open umbrella is achieved if its shaft points west. Why is it relatively easy to hold the umbrella directly into the wind (in this case, eastward) but very difficult to hold it perpendicular to the wind?

11.21 A sculptor and his assistant are carrying a wedge-shaped marble slab up a flight of stairs, as shown in the figure. The density of the marble is uniform. Both are lifting straight up as they hold the slab completely stationary for a moment. Does the sculptor have to exert more force than the assistant to keep the slab stationary? Explain.

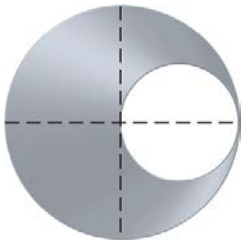
11.22 As shown in the figure, a thin rod of mass M and length L is suspended by two wires—one at the left end and one two-thirds of the distance from the left end to the right end.



a) What is the tension in each wire?

b) Determine the mass that an object hung by a string attached to the far right-hand end of the rod would have to have for the tension in the left-hand wire to be zero.

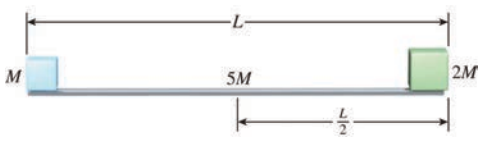
11.23 A uniform disk of mass M_1 and radius R_1 has a circular hole of radius R_2 cut out as shown in the figure.



a) Find the center of mass of the resulting object.

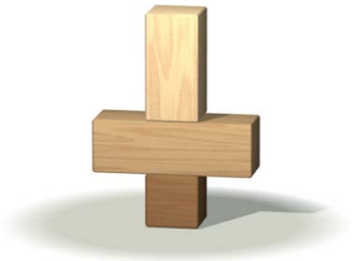
b) How many equilibrium positions does this object have when resting on its edge? Which ones are stable, which neutral, and which unstable?

11.24 Consider the system shown in the figure. If a pivot point is placed at a distance $L/2$ from the ends of the rod of length L and mass $5M$, the system will rotate clockwise. Thus, in order for the system to not rotate, the pivot point should be placed away from the center of the rod. In which direction from the center of the rod should the pivot point be placed? How far from the center of the rod should the pivot point be placed in order for the system not to rotate? (Treat masses M and $2M$ as point masses.)



11.25 A child has a set of blocks that are all made from the same type of wood. The blocks come in three shapes: a cube of side L, a piece the size of two cubes, and a piece equivalent in size to three of the cubes placed end to end. The child stacks three blocks as shown in the figure: a cube on the bottom, one of the longest blocks

horizontally on top of that, and the medium-sized block placed vertically on top. The centers of each block are initially on a vertical line. How far can the top block be slid along the middle block before the middle block tips?



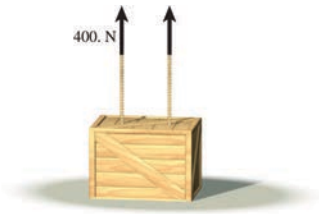
11.26 Why didn't the ancient Egyptians build their pyramids upside-down? In other words, use force and center-of-mass principles to explain why it is more advantageous to construct buildings with broad bases and narrow tops than the other way around.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 11.1

11.27 A 1000.-N crate of length L rests on a horizontal platform. It is being pulled up by two vertical ropes. The left rope has a tension of 400. N and is attached a distance of $L/4$ from the left end of the crate. Assuming the platform moves downward and the crate does not move or rotate, what can you say about the tension in the right rope?



11.28 In preparation for a demonstration on conservation of energy, a professor attaches a 5.00-kg bowling ball to a 4.00-m-long rope. He pulls the ball 20.0° away from the vertical and holds the ball while he discusses the physics principles involved. Assuming that the force he exerts on the ball is entirely in the horizontal direction, find the tension in the rope and the force the professor is exerting on the ball.

11.29 A sculptor and his assistant stop for a break as they carry a marble slab of length $L = 2.00$ m and mass 75.0 kg up the steps, as shown in the figure. The mass of the slab is uniformly distributed along its length. As they rest, both the sculptor and his assistant are pulling *directly up* on each end of the slab, which is at an angle of 30.0° with respect to horizontal. What are the magnitudes of the forces that the sculptor and assistant must exert on the marble slab to keep it stationary during their break?

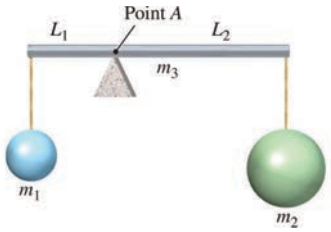
11.30 During a picnic, you and two of your friends decide to have a three-way tug-of-war, so you tie the ends of three ropes into a knot. Roberta pulls to the west with 420. N of force; Michael pulls to the south with 610. N. In what direction and with what magnitude of force should you pull to keep the knot from moving?

W. Bauer and G. D. Westfall

11.31 The figure shows a photo of a typical merry-go-round, like those found on many playgrounds, and a diagram giving a top view. Four children are standing on the ground and pulling on the merry-go-round as indicated by the force arrows. The four forces have the magnitudes $F_1 = 104.9$ N, $F_2 = 89.1$ N, $F_3 = 62.8$ N, and $F_4 = 120.7$ N. All the forces act in a tangential direction. With what force, $\vec{F}$, also in a tangential direction and acting at the black point, does a fifth child have to pull in order to prevent the merry-go-round from moving? Specify the magnitude of the force and state whether the force is acting counterclockwise or clockwise.

11.32 A trapdoor on a stage has a mass of 19.2 kg and a width of 1.50 m (hinge side to handle side). The door can be treated as having uniform thickness and density. A small handle on the door is 1.41 m away from the hinge side. A rope is tied to the handle and used to raise the door. At one instant, the rope is horizontal, and the trapdoor has been partly opened so that the handle is 1.13 m above the floor. What is the tension, T, in the rope at this time?

•**11.33** A rigid rod of mass m_3 is pivoted at point A, and masses m_1 and m_2 are hanging from it, as shown in the figure.



a) What is the normal force acting on the pivot point?

b) What is the ratio of L_1 to L_2, where these are the distances from the pivot point to m_1 and m_2, respectively? The ratio of the weights of m_1, m_2, and m_3 is 1:2:3.

•**11.34** When only the front wheels of an automobile are on a platform scale, the scale balances at 8.00 kN; when only the rear wheels are on the scale, it balances at 6.00 kN. What is the weight of the automobile, and how far is its center of mass behind the front axle? The distance between the axles is 2.80 m.

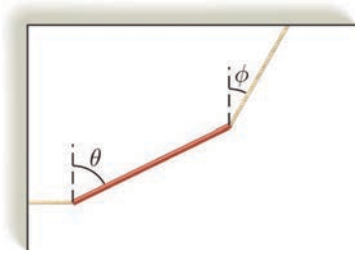
•**11.35** By considering the torques about your shoulder, estimate the force your deltoid muscles (those on top of the shoulder) must exert on the bone of your upper arm, in order to keep your arm extended straight out at shoulder level. Then, estimate the force the muscles must exert to hold a 10.0-lb weight at arm's length. You'll need to estimate the distance from your shoulder pivot point to the point where your deltoid muscles connect to the bone of your upper arm in order to determine the necessary forces. Assume the deltoids are the only contributing muscles.

••**11.36** A uniform, equilateral triangle of side length 2.00 m and weight $4.00 \cdot 10^3$ N is placed across a gap. One point is on the north end of the gap, and the opposite side is on the south end. Find the force on each side.

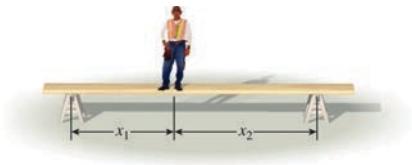
Section 11.2

11.37 A 600.0-N bricklayer is 1.50 m from one end of a uniform scaffold that is 7.00 m long and weighs 800.0 N. A pile of bricks weighing 500.0 N is 3.00 m from the same end of the scaffold. If the scaffold is supported at both ends, calculate the force on each end.

11.38 The uniform rod in the figure is supported by two strings. The string attached to the wall is horizontal, and the string attached to the ceiling makes an angle of ϕ with respect to the vertical. The rod itself is tilted from the vertical by an angle θ. If $\phi = 30.0^\circ$, what is the value of θ?



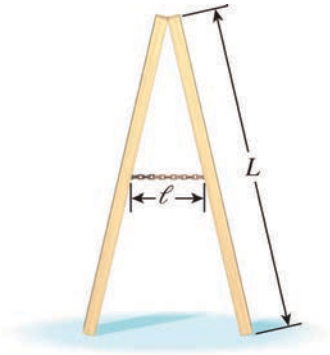
11.39 A construction supervisor of mass $M = 92.1$ kg is standing on a board of mass $m = 27.5$ kg. Two sawhorses at a distance $\ell = 3.70$ m apart support the board, which overhangs each sawhorse by an equal amount. If the man stands a distance $x_1 = 1.07$ m away from the left-hand sawhorse as shown in the figure, what is the force that the board exerts on that sawhorse?



Creatas/Getty Images

11.40 In a butcher shop, a horizontal steel bar of mass 4.00 kg and length 1.20 m is supported by two vertical wires attached to its ends. The butcher hangs a sausage of mass 2.40 kg from a hook that is at a distance of 0.20 m from the left end of the bar. What are the tensions in the two wires?

•**11.41** Two uniform planks, each of mass m and length L, are connected by a hinge at the top and by a chain of negligible mass attached at their centers, as shown in the figure. The assembly will stand upright, in the shape of an A, on a frictionless surface without collapsing. As a function of the length of the chain, find each of the following:

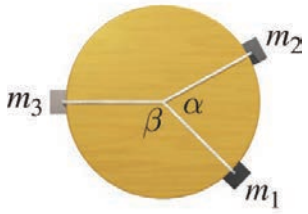


a) the tension in the chain,

b) the force on the hinge of each plank, and

c) the force of the ground on each plank.

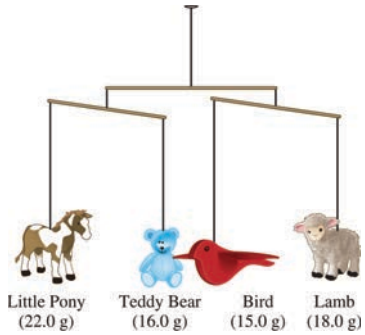
•**11.42** Three strings are tied together. They lie on top of a circular table, and the knot is exactly in the center of the table, as shown in the figure (top view). Each string hangs over the edge of the table, with a weight supported from it. The masses $m_1 = 4.30$ kg and $m_2 = 5.40$ kg are known. The angle $\alpha = 74^\circ$ between strings 1 and 2 is also known. What is the angle β between strings 1 and 3?



•**11.43** A uniform ladder 10.0 m long is leaning against a frictionless wall at an angle of 60.0° above the horizontal. The weight of the ladder is 20.0 lb. A 61.0-lb boy climbs 4.00 m up the ladder. What is the magnitude of the frictional force exerted on the ladder by the floor?

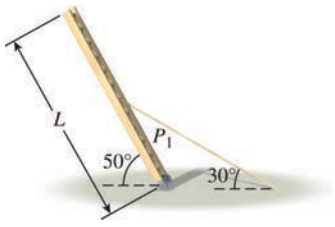
•**11.44** Robin is making a mobile to hang over her baby sister's crib. She purchased four stuffed animals: a teddy bear (16.0 g), a lamb

(18.0 g), a little pony (22.0 g), and a bird (15.0 g). She also purchased three small wooden dowels, each 15.0 cm long and of mass 5.00 g, and thread of negligible mass. She wants to hang the bear and the pony from the ends of one dowel and the lamb and the bird from the ends of the second dowel. Then, she wants to suspend the two dowels from the ends of the third dowel and hang the whole assembly from the ceiling. Explain where the thread should be attached on each dowel so that the entire assembly will hang level.



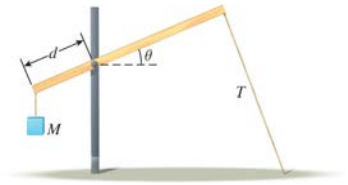
•**11.45** A door, essentially a uniform rectangle of height 2.00 m, width 0.800 m, and weight 100.0 N, is supported at one edge by two hinges, one 30.0 cm above the bottom of the door and one 170.0 cm above the bottom of the door. Calculate the horizontal components of the forces on the two hinges.

••**11.46** The figure shows a 20.0-kg, uniform ladder of length L hinged to a horizontal platform at point P_1 and anchored with a steel cable of the same length as the ladder attached at the ladder's midpoint. Calculate the tension in the cable and the forces in the hinge when an 80.0-kg person is standing three-quarters of the way up the ladder.

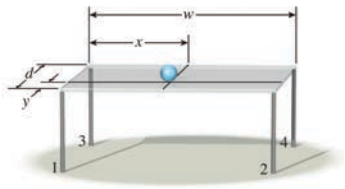


••**11.47** A beam with a length of 8.00 m and a mass of 100. kg is attached by a large bolt to a support at a distance of $d = 3.00$ m from one end. The beam makes an angle $\theta = 30.0^\circ$ with the horizontal, as shown in the figure. A mass $M = 500.$ kg is attached with a rope to one end of the beam, and a second rope is attached at a right angle to

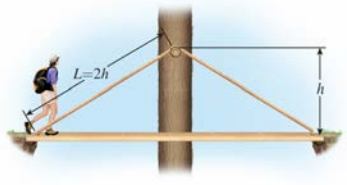
the other end of the beam. Find the tension, T, in the second rope and the force exerted on the beam by the bolt.



••**11.48** A ball of mass 15.49 kg rests on a table of height 0.720 m. The tabletop is a rectangular glass plate of mass 12.13 kg, which is supported at the corners by thin legs, as shown in the figure. The width of the tabletop is $w = 138.0$ cm, and its depth is $d = 63.8$ cm. If the ball touches the tabletop at a point $(x, y) = (69.0 \text{ cm}, \ 16.6 \text{ cm})$ relative to corner 1, what is the force that the tabletop exerts on each leg?

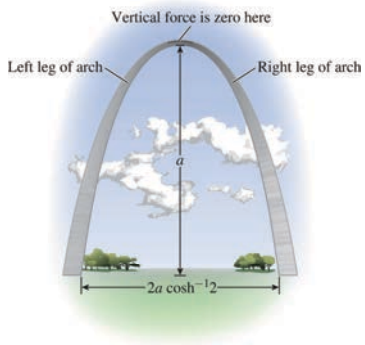


••**11.49** A wooden bridge crossing a canyon consists of a plank with length density $\lambda = 2.00$ kg/m suspended at $h = 10.0$ m below a tree branch by two ropes, each with a length $L = 2h$ and a maximum rated tension of 2000. N, which are attached to the ends of the plank, as shown in the figure. A hiker steps onto the bridge from the left side, causing the bridge to tip to an angle of 25.0° with respect to the horizontal. What is the mass of the hiker?



••**11.50** The famous Gateway Arch in St. Louis, Missouri, is approximately an *inverted catenary*. A simple example of such a curve is given by $y(x) = 2a - a\cosh(x/a)$, where y is vertical height and x is horizontal distance, measured from directly under the top of the curve; thus, x varies from $-a \cosh^{-1}2$ to $+a \cosh^{-1}2$, with a the

height of the top of the curve (see the figure). Suppose an arch of uniform cross section and density, with total weight W, has this shape. The two legs of the arch exert only horizontal forces on each other at the top; ideally, the stress there should be uniform compression across the cross section.



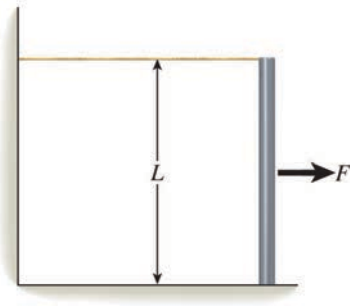
a) Calculate the vertical and horizontal force components that are acting at the base of each leg of this arch.

b) At what angle should the bottom face of the legs be oriented?

Section 11.3

11.51 A uniform rectangular bookcase of height H and width $W = H/2$ is to be pushed at a constant velocity across a level floor. The bookcase is pushed horizontally at its top edge, at the distance H above the floor. What is the maximum value the coefficient of kinetic friction between the bookcase and the floor can have if the bookcase is not to tip over while being pushed?

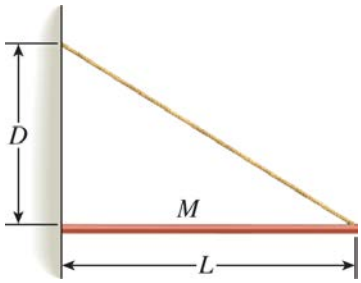
11.52 The system shown in the figure is in static equilibrium. The rod of length L and mass M is held in an upright position. The top of the rod is tied to a fixed vertical surface by a string, and a force F is applied at the midpoint of the rod. The coefficient of static friction between the rod and the horizontal surface is μ_s. What is the maximum force, F, that can be applied and have the rod remain in static equilibrium?



11.53 A ladder of mass 37.7 kg and length 3.07 m is leaning against a wall at an angle θ. The coefficient of static friction between ladder and floor is 0.313; assume that the friction force between ladder and wall is zero. What is the maximum value that θ can have before the ladder starts slipping?

W. Bauer and G. D. Westfall

•**11.54** A uniform rigid pole of length L and mass M is to be supported from a vertical wall in a horizontal position, as shown in the figure. The pole is not attached directly to the wall, so the coefficient of static friction, μ_s, between the wall and the pole provides the only vertical force on one end of the pole. The other end of the pole is supported by a light rope that is attached to the wall at a point a distance D directly above the point where the pole contacts the wall. Determine the minimum value of μ_s, as a function of L and D, that will keep the pole horizontal and not allow its end to slide down the wall.



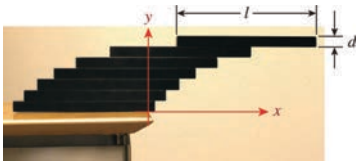
•**11.55** A boy weighing 60.0 lb is playing on a plank. The plank weighs 30.0 lb, is uniform, is 8.00 ft long, and lies on two supports, one 2.00 ft from the left end and the other 2.00 ft from the right end.

a) If the boy is 3.00 ft from the left end, what force is exerted by each support?

b) The boy moves toward the right end. How far can he go before the plank will tip?

•**11.56** A track has a height that is a function of horizontal position x, given by $h(x) = x^3 + 3x^2 - 24x + 16$. Find all the positions on the track where a marble will remain where it is placed. What kind of equilibrium exists at each of these positions?

•**11.57** The figure shows a stack of seven identical aluminum blocks, each of length $l = 15.9$ cm and thickness $d = 2.20$ cm, stacked on a table.



W. Bauer and G. D. Westfall

a) How far to the right of the edge of the table is it possible for the right edge of the top (seventh) block to extend?

b) What is the minimum height of a stack of these blocks for which the left edge of the top block is to the right of the right edge of the table?

•**11.58** You are using a 5.00-m-long ladder to paint the exterior of your house. The point of contact between the ladder and the siding of the house is 4.00 m above the ground. The ladder has a mass of 20.0 kg. If you weigh 60.0 kg and stand three-quarters of the way up the ladder, determine

a) the forces exerted by the side wall and the ground on the ladder and

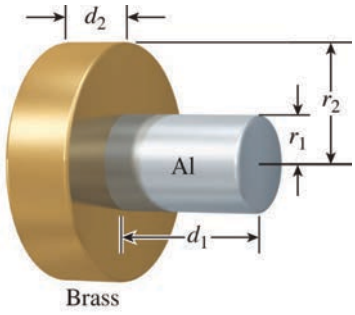
b) the coefficient of static friction between the ground and the base of the ladder that is necessary to keep the ladder stable.

•**11.59** A ladder of mass M and length $L = 4.00$ m is on a level floor leaning against a vertical wall. The coefficient of static friction between the ladder and the floor is $\mu_s = 0.600$, while the friction between the ladder and the wall is negligible. The ladder is at an angle of $\theta = 50.0^\circ$ above the horizontal. A man of mass $3M$ starts to climb the ladder. To what distance up the ladder can the man climb before the ladder starts to slip on the floor?

•**11.60** A machinist makes the object shown in the figure. The larger-diameter cylinder is made of brass $\left(\text{mass density} = 8.60\ \text{g/cm}^3\right)$; the smaller-diameter cylinder is made of aluminum $\left(\text{mass density} = 2.70\ \text{g/cm}^3\right)$. The dimensions are $r_1 = 2.00$ cm, $r_2 = 4.00$ cm, $d_1 = 20.0$ cm, and $d_2 = 4.00$ cm.

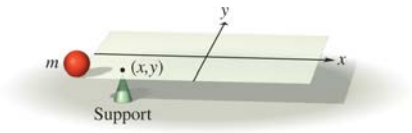
a) Find the location of the center of mass.

b) If the object is on its side, as shown in the figure, is it in equilibrium? If yes, is this stable equilibrium?



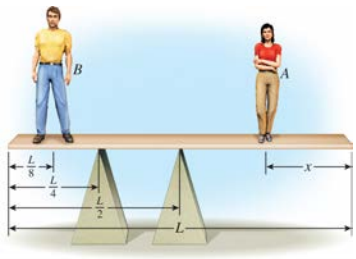
•**11.61** An object is restricted to movement in one dimension. Its position is specified along the x-axis. The potential energy of the object as a function of its position is given by $U(x) = a\left(x^4 - 2b^2x^2\right)$, where a and b represent positive numbers. Determine the location(s) of any equilibrium point(s), and classify the equilibrium at each point as stable, unstable, or neutral.

•**11.62** A two-dimensional object with uniform mass density is in the shape of a thin square and has a mass of 2.00 kg. The sides of the square are each 20.0 cm long. The coordinate system has its origin at the center of the square. A point mass, m, of $2.00 \cdot 10^2$ g is placed at one corner of the square object, and the assembly is held in equilibrium by positioning the support at position (x,y), as shown in the figure. Find the location of the support.

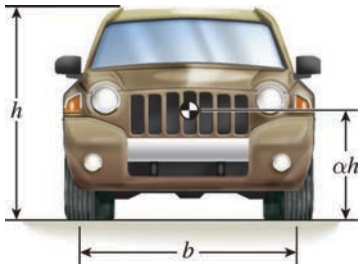


•**11.63** Persons A and B are standing on a board of uniform linear density that is balanced on two supports, as shown in the figure. What is the maximum distance x from the right end of the board at which person A can stand without tipping the board? Treat persons A

and B as point masses. The mass of person B is twice that of person A, and the mass of the board is half that of person A. Give your answer in terms of L, the length of the board.



••11.64 An SUV has a height h and a wheelbase of length b. Its center of mass is midway between the wheels and at a distance αh above the ground, where $0 < \alpha < 1$. The SUV enters a turn at a dangerously high speed, v. The radius of the turn is $R(R \gg b)$, and the road is flat. The coefficient of static friction between the road and the properly inflated tires is μ_s. After entering the turn, the SUV will either skid out of the turn or begin to tip.



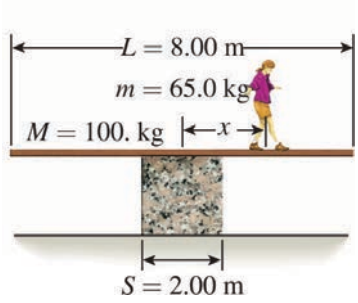
a) The SUV will skid out of the turn if the friction force reaches its maximum value, $F \rightarrow \mu_s N$. Determine the speed, v_{skid}, for which this will occur. Assume no tipping occurs.

b) The torque keeping the SUV from tipping acts on the outside wheel. The highest value that the force responsible for this torque can have is equal to the entire normal force. Determine the speed, v_{tip}, at which tipping will occur. Assume no skidding occurs.

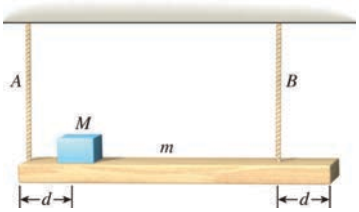
c) It is safer if the SUV skids out before it tips. This will occur as long as $v_{\text{skid}} < v_{\text{tip}}$. Apply this condition, and determine the maximum value for α in terms of b, h and μ_s.

Additional Exercises

11.65 A wooden plank with length $L = 8.00$ m and mass $M = 100.$ kg is centered on a granite cube with side $S = 2.00$ m. A person of mass $m = 65.0$ kg begins walking from the center of the plank outward, as shown in the figure. How far from the center of the plank does the person get before the plank starts tipping?

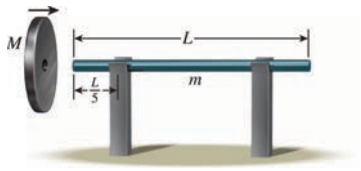


11.66 A board, with a weight $mg = 120.0$ N and a length of 5.00 m, is supported by two vertical ropes, as shown in the figure. Rope A is connected to one end of the board, and rope B is connected at a distance $d = 1.00$ m from the other end of the board. A box with a weight $Mg = 20.0$ N is placed on the board with its center of mass at $d = 1.00$ m from rope A. What are the tensions in the two ropes?



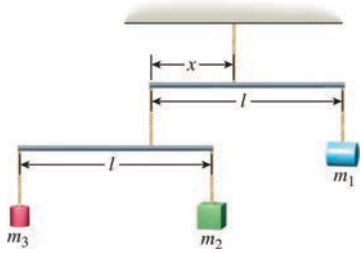
11.67 In a car, which is accelerating at 5.00 m/s^2, an air freshener is hanging from the rear-view mirror, with the string maintaining a constant angle with respect to the vertical. What is this angle?

11.68 Typical weight sets used for bodybuilding consist of disk-shaped weights with holes in the center that can slide onto 2.20-m-long barbells. A barbell is supported by racks located a fifth of its length from each end, as shown in the figure. What is the minimum mass m of the barbell if a bodybuilder is to slide a weight with $M = 22.0$ kg onto the end without the barbell tipping off the rack? Assume that the barbell is a uniform rod.

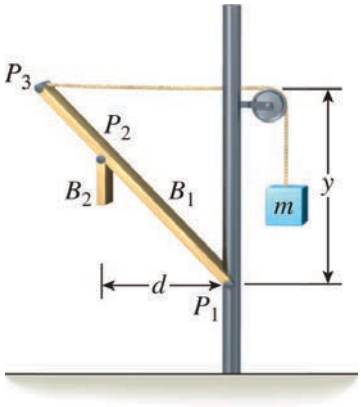


11.69 A 5.00-m-long board of mass 50.0 kg is used as a seesaw. On the left end of the seesaw sits a 45.0-kg girl, and on the right end sits a 60.0-kg boy. Determine the position of the pivot point for static equilibrium.

11.70 A mobile consists of two very lightweight rods of length $l = 0.400$ m connected to each other and the ceiling by vertical strings. (Neglect the masses of the rods and strings.) Three objects are suspended by strings from the rods. The masses of objects 1 and 3 are $m_1 = 6.40$ kg and $m_3 = 3.20$ kg. The distance x shown in the figure is 0.160 m. What is the mass of m_2?

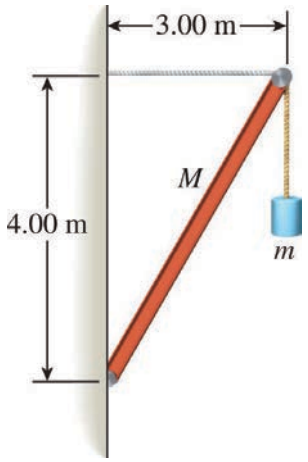


•**11.71** In the experimental setup shown in the figure, a beam, B_1, of unknown mass M_1 and length $L_1 = 1.00$ m is pivoted about its lowest point at P_1. A second beam, B_2, of mass $M_2 = 0.200$ kg and length $L_2 = 0.200$ m is suspended (pivoted) from B_1 at a point P_2, which is a horizontal distance $d = 0.550$ m from P_1. To keep the system at equilibrium, a mass $m = 0.500$ kg has to be suspended from a massless string that runs horizontally from P_3, at the top of beam B_1, and passes over a frictionless pulley. The string runs at a vertical distance $y = 0.707$ m above the pivot point P_1. Calculate the mass of beam B_1.



•**11.72** An important characteristic of the condition of static equilibrium is the fact that the net torque has to be zero irrespective of the choice of pivot point. For the setup in Problem 11.71, prove that the torque is indeed zero with respect to a pivot point at P_1, P_2, or P_3.

•**11.73** One end of a heavy beam of mass $M = 50.0$ kg is hinged to a vertical wall, and the other end is tied to a steel cable of length 3.00 m, as shown in the figure. The other end of the cable is also attached to the wall at a distance of 4.00 m above the hinge. A mass $m = 20.0$ kg is hung from one end of the beam by a rope.

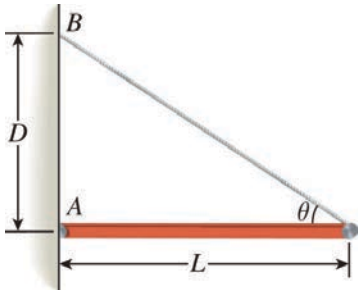


a) Determine the tensions in the cable and the rope.

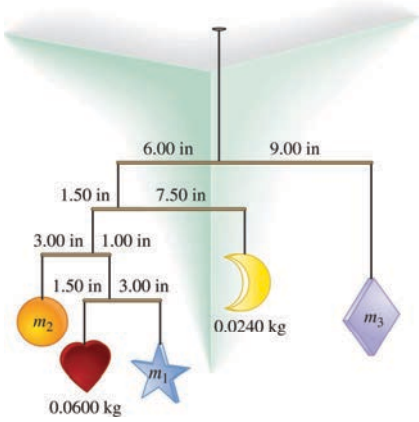
b) Find the force the hinge exerts on the beam.

•**11.74** A 100.-kg uniform bar of length $L = 5.00$ m is attached to a wall by a hinge at point A and supported in a horizontal position by a light cable attached to its other end. The cable is attached to the wall at point B, at a distance $D = 2.00$ m above point A. Find: a) the

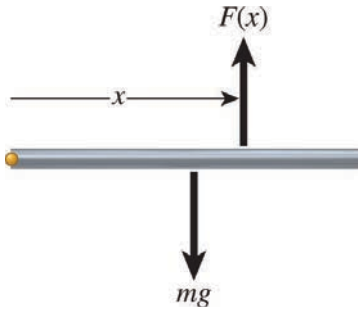
tension, T, on the cable and b) the horizontal and vertical components of the force acting on the bar at point A.



•11.75 A mobile over a baby's crib displays small colorful shapes. What values for m_1, m_2, and m_3 are needed to keep the mobile balanced (with all rods horizontal)?



•11.76 Consider the rod of length L shown in the figure. The mass of the rod is $m = 2.00$ kg, and the pivot point is located at the left end (at $x = 0$). In order to prevent the rod from rotating, a variable force given by $F(x) = (15.0\ \text{N})(x/L)^4$ is applied to the rod. At what point x on the rod should the force be applied in order to keep it from rotating?



•**11.77** A pipe that is 2.20 m long and has a mass of 8.13 kg is suspended horizontally over a stage by two chains, each located 0.20 m from an end. Two 7.89-kg theater lights are clamped onto the pipe, one 0.65 m from the left end and the other 1.14 m from the left end. Calculate the tension in each chain.

•**11.78** A 2.00-m-long diving board of mass 12.0 kg is 3.00 m above the water. It has two attachments holding it in place. One is located at the very back end of the board, and the other is 25.0 cm away from that end.

a) Assuming that the board has uniform density, find the forces acting on each attachment (take the downward direction to be positive).

b) If a diver of mass 65.0 kg is standing on the front end, what are the forces acting on the two attachments?

•**11.79** A 20.0-kg box with a height of 80.0 cm and a width of 30.0 cm has a handle on the side that is 50.0 cm above the ground. The box is at rest, and the coefficient of static friction between the box and the floor is 0.280.

a) What is the minimum force, F, that can be applied to the handle so that the box will tip over without slipping?

b) In what direction should this force be applied?

••**11.80** The angular displacement of a torsional spring is proportional to the applied torque; that is $\tau = \kappa\theta$, where κ is a constant. Suppose that such a spring is mounted to an arm that moves in a vertical plane. The mass of the arm is 45.0 g, and it is 12.0 cm long. The arm-spring system is at equilibrium with the arm at an angular displacement of 17.0° with respect to the horizontal. If a mass of 0.420 kg is hung from the arm 9.00 cm from the axle, what

will be the angular displacement in the new equilibrium position (relative to that with the unloaded spring)?

MULTI-VERSION EXERCISES

11.81 A horizontal bar that is 2.141 m long and has a mass of 81.95 kg is hinged to a wall. The bar is supported at its other end by a cable attached to the wall, which makes an angle of $\theta = 38.89^\circ$ with the bar. What is the tension in the cable?

11.82 A horizontal bar that is 2.261 m long and has a mass of 82.45 kg is hinged to a wall. The bar is supported at its other end by a cable attached to the wall. The cable has a tension of 618.8 N. What is the angle between the cable and the bar?

11.83 A horizontal bar that is 2.381 m long is hinged to a wall. The bar is supported at its other end by a cable attached to the wall, which makes an angle of $\theta = 42.75^\circ$ with the bar. The cable has a tension of 599.3 N. What is the mass of the bar?

11.84 A uniform, rectangular refrigerator with a height $h = 2.177$ m and a width $w = 1.247$ m has a mass of 98.57 kg. It is pushed at a constant velocity across a level floor by a force in the horizontal direction that is applied halfway between the floor and the top of the refrigerator. The refrigerator does not tip over while being pushed. What is the maximum value of the coefficient of kinetic friction between the refrigerator and the floor?

11.85 A uniform, rectangular refrigerator with a height $h = 2.187$ m and a width w has a mass of 83.91 kg. It is pushed at a constant velocity across a level floor by a force in the horizontal direction that is applied halfway between the floor and the top of the refrigerator. The refrigerator does not tip over while being pushed. The coefficient of kinetic friction between the refrigerator and the floor is 0.4696. What is the minimum width, w, of the refrigerator?

11.86 A uniform, rectangular refrigerator with a width $w = 1.059$ m and a height h has a mass of 88.27 kg. It is pushed at a constant velocity across a level floor by a force in the horizontal direction that

is applied halfway between the floor and the top of the refrigerator. The refrigerator does not tip over while being pushed. The coefficient of kinetic friction between the refrigerator and the floor is 0.4820. What is the maximum height, h, of the refrigerator?

11.87 A 92.61-kg person is halfway up a uniform ladder of length 3.413 m and mass 23.63 kg that is leaning against a wall. The angle between the ladder and the wall is θ. The coefficient of static friction between the ladder and the floor is 0.2881. Assume that the friction force between the ladder and the wall is zero. What is the maximum value that the angle between the ladder and the wall can have without the ladder slipping?

11.88 A 96.97-kg person is halfway up a uniform ladder of length 3.433 m and mass 24.91 kg that is leaning against a wall. The angle between the ladder and the wall is $\theta = 27.30^\circ$. Assume that the friction force between the ladder and the wall is zero. What is the minimum value of the coefficient of static friction between the ladder and the floor that will keep the ladder from slipping?

Figure 12.1 shows the Earth setting over the horizon of the Moon, photographed by a satellite orbiting the Moon. We are so used to seeing the Moon in the sky that it's somewhat surprising to see the Earth instead. In fact, astronauts on the Moon do not see earthrise or earthset because the Moon always keeps the same face turned toward Earth. Only astronauts orbiting the Moon can see the Earth seeming to change position and rise or set. However, the image reminds us that, like all forces, the force of gravity is a mutual attraction between two objects—Earth pulls on the Moon, but the Moon also pulls on Earth.

FIGURE 12.1 The Earth and the Moon orbit around each other and are kept together by their gravitational interaction.

NASA

We have examined forces in general terms in previous chapters. In this chapter, we focus on one particular force, the force of gravity, which is one of the four fundamental forces in nature. Gravity is the weakest of these four forces (inside atoms, for example, gravity is negligible relative to the electromagnetic forces), but it operates over all distances and is always a force of attraction between objects with mass (as opposed to the electromagnetic interaction, for which the charges come in positive and negative varieties so resulting forces can be attractive or repulsive and tend to sum to zero for most macroscopic objects). As a result, the gravitational

force is of primary importance over the vast distances and for the enormous masses involved in astronomical studies.

WHAT WE WILL LEARN

- The gravitational interaction between two point masses is proportional to the product of their masses and inversely proportional to the square of the distance separating them.
- The gravitational force on an object inside a homogeneous solid sphere rises linearly with the distance that the object is from the center of the solid sphere.
- At the surface of the Earth, the acceleration due to gravity is well approximated by a constant, g. The value of g used for free-fall situations can be verified from the more general gravitational force law.
- A general expression for the gravitational potential energy indicates that it is inversely proportional to the distance between two objects.
- Escape speed is the minimum speed with which a projectile must be launched to escape to an infinite distance from Earth (or another body).
- Kepler's three laws of planetary motion state that planets move in elliptical orbits with the Sun at one focal point, that the radius vector connecting the Sun and a planet sweeps out equal areas in equal times, and that the square of the orbit's period for any planet is proportional to the cube of its semimajor axis.
- The kinetic, potential, and total energies of satellites in orbit have a fixed relationship with each other.
- There is evidence for a great amount of dark matter and dark energy in the universe.

Figure 12.2 is an image of the center of our galaxy obtained with the space-based infrared Spitzer telescope. The galactic center contains a supermassive black hole, and knowledge of the gravitational interaction allows astronomers to calculate that the mass of this black hole is

approximately 4.1 million times the mass of the Sun or more than 1 trillion times the mass of the Earth. (Example 12.4 shows how scientists arrived at this conclusion. A black hole is an object so massive and dense that nothing can escape from its surface, not even light.)

FIGURE 12.2 Center of our galaxy, the Milky Way, which contains a supermassive black hole. The size of the region shown here is 890 by 640 light-years. The Solar System is 26,000 light-years away from the center of the galaxy.

JPL-Caltech/S. Stolovy (SSC/Caltech)/NASA

12.1 Newton's Law of Gravity

Up to now, we have encountered the gravitational force only in the form of a constant gravitational acceleration, $g = 9.81\ \mathrm{m/s^2}$, multiplied by the mass of the object on which the force acts. However, from videos of astronauts running and jumping on the Moon (Figure 12.3), we know that the gravitational force is different there. Therefore, the approximation we have used of a constant gravitational force that depends only on the mass of the object the force acts on cannot be correct away from the surface of the Earth.

FIGURE 12.3 *Apollo 16* Commander John Young jumps on the surface of the Moon and salutes the U.S. flag on April 21, 1972.

NASA

The general expression for the magnitude of the gravitational interaction between two point masses, m_1 and m_2, at a distance $r = \left|\vec{r_2} - \vec{r_1}\right|$ from each other (Figure 12.4) is

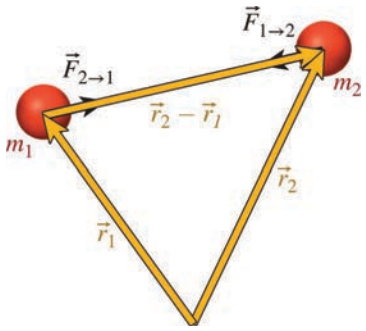

FIGURE 12.4 The gravitational interaction of two point masses.

$$F(r) = G\frac{m_1 m_2}{r_2}. \tag{12.1}$$

This relationship, known as **Newton's Law of Gravity,** is an empirical law, deduced from experiments and verified extensively. The proportionality constant G is called the **universal gravitational constant** and has the value (to four significant figures)

$$G = 6.6738.10^{-11}\,\mathrm{N\,m^2/kg^2}. \tag{12.2}$$

Since $1\,\mathrm{N} = 1\,\mathrm{kg\,m/s^2}$, we can also write this value as $G = 6.6738 \cdot 10^{-11}\,\mathrm{m^3 kg^{-1} s^{-2}}$. Equation 12.1 says that the strength of the gravitational interaction is proportional to each of the two masses involved in the interaction and is inversely proportional to the square of the distance between them. For example, doubling one of the masses will double the strength of the interaction, whereas doubling the distance will reduce the strength of the interaction by a factor of 4.

Because a force is a vector, the direction of the gravitational force must be specified. The gravitational force $\overrightarrow{F}_{2\to1}$ acting from object 2 on object 1 always points toward object 2. We can express this concept in the form of an equation:

$$\overrightarrow{F}_{2\to1} = F(r)\hat{r}_{21} = F(r)\frac{\overrightarrow{r_2} - \overrightarrow{r_1}}{\left|\overrightarrow{r_2} - \overrightarrow{r_1}\right|}.$$

Combining this result with equation 12.1 results in

$$\vec{F}_{2\to 1} = G\frac{m_1 m_2}{\left|\vec{r}_2 - \vec{r}_1\right|^3}\left(\vec{r}_2 - \vec{r}_1\right). \qquad \textbf{(12.3)}$$

Equation 12.3 is the general form for the gravitational force acting on object 1 due to object 2. It is strictly valid for point particles, as well as for extended spherically symmetrical objects, in which case the position vector is the position of the center of mass. It is also a very good approximation for nonspherical extended objects, represented by their center-of-mass coordinates, provided that the separation between the two objects is large relative to their individual sizes. Note that the center of gravity is identical to the center of mass for spherically symmetrical objects.

Chapter 4 introduced Newton's Third Law: The force $\vec{F}_{1\to 2}$ exerted on object 2 by object 1 has to be of the same magnitude as and in the opposite direction to the force $\vec{F}_{2\to 1}$ exerted on object 1 by object 2:

$$\vec{F}_{1\to 2} = -\vec{F}_{2\to 1}.$$

You can see that the force described by equation 12.3 fulfills the requirements of Newton's Third Law by exchanging the indexes 1 and 2 on all variables (F, m, and r) and observing that the magnitude of the force remains the same, but the sign changes. Equation 12.3 governs the motion of the planets around the Sun, as well as of objects in free fall near the surface of the Earth.

Superposition of Gravitational Forces

If more than one object has a gravitational interaction with object 1, we can compute the total gravitational force on object 1 by using the **superposition principle,** which states that the vector sum of all gravitational forces on a specific object yields the total gravitational force on that object. That is, to find the total gravitational force acting on an object, we simply add the contributions from all other objects:

$$\vec{F}_1 = \vec{F}_{2\to 1} + \vec{F}_{3\to 1} + \cdots + \vec{F}_{n\to 1} = \sum_{i=2}^{n} \vec{F}_{i\to 1}. \qquad \textbf{(12.4)}$$

The individual forces $\vec{F}_{i\to 1}$ can be found from equation 12.3:

$$\vec{F}_{i\to 1} = G\frac{m_i m_1}{\left|\vec{r}_i - \vec{r}_1\right|^3}\left(\vec{r}_i - \vec{r}_1\right).$$

Conversely, the total gravitational force on any one of *n* objects experiencing mutual gravitational interaction can be written as

$$\vec{F}_j = \sum_{i=1, i\neq j}^{n} \vec{F}_{i\to j} = G\sum_{i=1, i\neq j}^{n} \frac{m_i m_j}{\left|\vec{r}_i - r_j\right|^3}\left(\vec{r}_i - \vec{r}_j\right). \qquad \textbf{(12.5)}$$

The notation "$i \neq j$" below the summation symbol indicates that the sum of forces does not include any object's interaction with itself.

The conceptualization of the superposition of forces is straightforward, but the solution of the resulting equations of motion can become complicated. Even in a system of three approximately equal masses that interact with one another, some initial conditions can lead to regular trajectories, whereas others lead to chaotic motion. The numerical investigation of this kind of system started to become possible only with the advent of computers. Over the last 20 years, the field of many-body physics has developed into one of the most interesting in all of physics, and many intriguing endeavors are likely to be undertaken, such as studying the origin of galaxies from small initial fluctuations in the density of the universe.

DERIVATION 12.1 Gravitational Force from a Sphere

Earlier, it was claimed that the gravitational interaction of an extended spherically symmetrical object could be treated like that of a point particle with the same mass located at the center of mass of the extended sphere. We can prove this statement with the aid of calculus and some elementary geometry.

To start, we treat a sphere as a collection of concentric and very thin spherical shells. If we can prove that a thin spherical shell has the same gravitational interaction as a point particle located at its center, then the superposition principle implies that a solid sphere does, too.

Figure 12.5 shows a point particle of mass M located outside a spherical shell of mass m at a distance r from the center of the shell. We want to find the x-component of the force on the mass M due to a ring of angular width $d\phi$. This ring has a radius of $a = R\sin\phi$ and thus a circumference of $2\pi R\sin\phi$. It has a width of $R\,d\phi$, as shown in Figure 12.5, and thus a total area of $2\pi R^2 \sin\phi d\phi$. Because the mass m is homogeneously distributed over the spherical shell of area $4\pi R^2$, the differential mass of the ring is

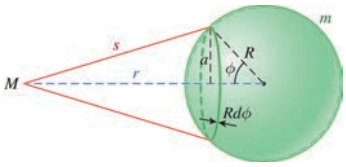

FIGURE 12.5
Gravitational force on a particle of mass *M* exerted by a spherical shell (hollow sphere) of mass *m*.

$$dm = m\frac{2\pi R^2 \sin\phi d\phi}{4\pi R^2} = \tfrac{1}{2} m \sin\phi d\phi.$$

Because the ring is positioned symmetrically around the horizontal axis, there is no net force in the vertical direction from the ring acting on the mass M. The horizontal force component is (Figure 12.6)

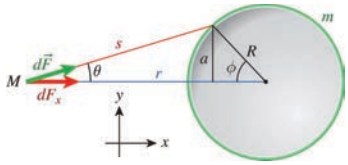

FIGURE 12.6 Cross section through the center of the spherical shell of Figure 12.5.

$$dF_x = \cos\theta\left(G\frac{Mdm}{s^2}\right) = \cos\theta\left(G\frac{Mm\sin\phi d\phi}{2s^2}\right). \qquad \text{(i)}$$

Now we can relate $\cos\theta$ to s, r, and R via the law of cosines:

$$\cos\theta = \frac{s^2 + r^2 - R^2}{2sr}.$$

In the same way,

$$\cos\phi = \frac{R^2 + r^2 - s^2}{2Rr}. \qquad \text{(ii)}$$

If we differentiate both sides of equation (ii), we obtain

$$-\sin\phi d\phi = -\frac{s}{Rr}ds.$$

Inserting the expressions for $\sin\phi d\phi$ and $\cos\theta$ into equation (i) for the differential force component gives

$$\begin{aligned} dF_x &= \frac{s^2 + r^2 - R^2}{2sr}\left(G\frac{Mm}{2s^2}\right)\frac{s}{Rr}ds \\ &= G\frac{Mm}{r^2}\left(\frac{s^2 + r^2 - R^2}{4s^2R}\right)ds. \end{aligned}$$

Now we can integrate over ds from the minimum value of $s = r - R$ to the maximum value of $s = r + R$:

$$F_x = \int_{r-R}^{r+R} G\frac{Mm}{r^2}\frac{(s^2+r^2-R^2)}{4s^2R}ds = G\frac{Mm}{r^2}\underbrace{\int_{r-R}^{r+R}\frac{s^2+r^2-R^2}{4s^2R}}_{\text{Equals 1}}$$

(It is not obvious that the value of the integral is 1, but you can look this up in an integral table.) Thus, a spherical shell (and by the superposition principle a solid sphere also) exerts the same force on the mass M as a point mass located at the center of the sphere, which is what we set out to prove.

Self-Test Opportunity 12.1

Derivation 12.1 assumes that $r > R$, which implies that the mass M is located outside the spherical shell. What changes if $r < R$?

The Solar System

The Solar System consists of the Sun, which contains the overwhelming majority of the total mass of the Solar System, the four Earthlike inner planets (Mercury, Venus, Earth, and Mars), the asteroid belt between the orbits of Mars and Jupiter, the four gas giants (Jupiter, Saturn, Uranus, and Neptune), a number of dwarf planets (including Ceres, Eris, Haumea, Makemake, and Pluto), and many other minor objects found in the Kuiper Belt. Figure 12.7 shows the orbits and relative sizes of the planets. Table 12.1 provides some physical data for the planets and the Sun.

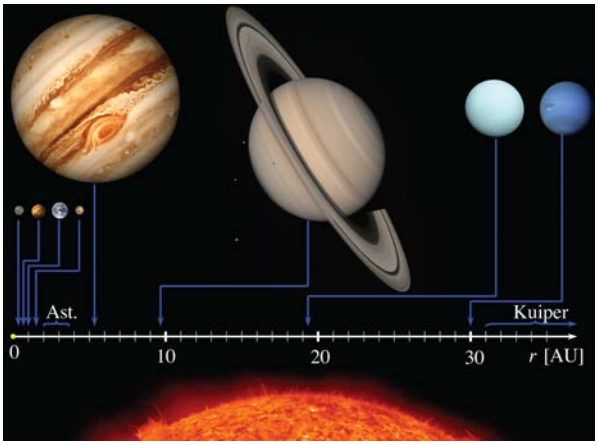

FIGURE 12.7 The Solar System. On this scale, the sizes of the planets themselves would be too small to be seen. The small yellow dot at the origin of the axis represents the Sun, but it is 30 times bigger than the Sun would appear if it were drawn to scale. The pictures of the planets and of part of the surface of the Sun (lower part of the figure) are all magnified by a factor of 20,000 relative to the scale for the orbits.

Sun	696,000	1,990,000	274	618	—	

Not listed as a planet is Pluto, and this omission deserves an explanation. The planet Neptune was discovered in 1846. This discovery had been predicted based on observed small irregularities in the orbit of Uranus, which hinted that another planet's gravitational interaction was the cause. Careful observations of the orbit of Neptune revealed more irregularities, which pointed toward the existence of yet another planet, and Pluto $\left(\text{mass} = 1.3 \cdot 10^{22}\ \text{kg}\right)$ was discovered in 1930. After that, schoolchildren were taught that the Solar System has nine planets. However, in 2003, Sedna $\left(\text{mass} = \sim 3 \cdot 10^{21}\ \text{kg}\right)$ and, in 2005, Eris $\left(\text{mass} = 1.7 \cdot 10^{22}\ \text{kg}\right)$ were discovered in the Kuiper Belt, a region in which various objects orbit the Sun at distances between 30 and 48 AU. When Eris's moon Dysnomia was discovered in late 2005, it allowed astronomers to calculate that Eris is more massive than Pluto, which began the discussion about what defines a planet. The choice was either to give Sedna, Eris, Ceres (an asteroid that was actually classified as a planet from 1801 to about 1850), and many other Plutolike objects in the Kuiper Belt the status of planet or to reclassify Pluto as a dwarf planet. In August 2006, the International Astronomical Union voted to remove full planetary status from Pluto.

As the story of Pluto shows, the Solar System still holds the potential for many discoveries. For example, almost 400,000 asteroids have been

identified, and about 5000 more are discovered each month. The total mass of all asteroids in the asteroid belt is less than 5% of the mass of the Moon. However, more than 200 of these asteroids are known to have a diameter of more than 100 km! Tracking them is very important, considering the damage one could cause if it hit the Earth. Another area of ongoing research is the investigation of the objects in the Kuiper Belt. Some models postulate that the combined mass of all Kuiper Belt objects is up to 30 times the mass of the Earth, but the observed mass so far is smaller than this value by a factor of about 1000.

EXAMPLE 12.1 Influence of Celestial Objects

Astronomy is the science that focuses on planets, stars, galaxies, and the universe as a whole. The similarly named field of astrology has no scientific basis whatsoever. It may be fun to read the daily horoscope, but constellations of stars and/or alignments of planets have no influence on our lives. The only way stars and planets can interact with us is through the gravitational force. Let's calculate the force of gravity exerted on a person by the Moon, Mars, and the stars in the constellation Gemini.

PROBLEM 1

Suppose you live in the Midwest of the United States. You go outside at 9:00 p.m. on February 16, 2008, and look up in the sky. On this particular night, you see the Moon, the planet Mars, and the constellation Gemini, as shown in Figure 12.8. Your mass is $m = 85\,\text{kg}$. What is the force of gravity on you due to these celestial objects?

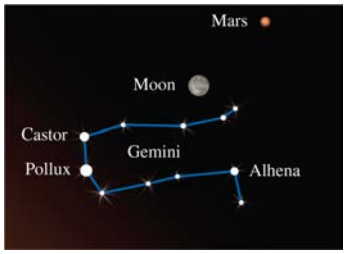

FIGURE 12.8
Relative positions of the Moon, Mars, and the constellation Gemini in the sky over the Midwest on February 16, 2008.

SOLUTION 1

Let's start with the Moon. The mass of the Moon is $7.35 \cdot 10^{22}\,\text{kg}$, and the distance from the Moon to you is $3.84 \cdot 10^{8}\,\text{m}$. The gravitational force the Moon exerts on you is then

$$F_{\text{Moon}} = G\frac{M_{\text{Moon}}m}{r_{\text{Moon}}^2} = \left(6.67 \cdot 10^{-11}\text{Nm}^2/\text{kg}^2\right)\frac{\left(7.35 \cdot 10^{22}\text{kg}\right)(85}{\left(3.84 \cdot 10^{8}\text{m}\right)^2}$$

The distance between Mars and Earth on February 16, 2008, was 136 million km, and the mass of Mars is $M_{\text{Mars}} = 6.4 \cdot 10^{23}\text{kg}$. Thus, the gravitational force that Mars exerts on you is

$$F_{\text{Mars}} = G\frac{M_{\text{Mars}}m}{r_{\text{Mars}}^2} = \left(6.67 \cdot 10^{-11}\ \text{N}\,\text{m}^2/\text{kg}^2\right)\frac{\left(6.4 \cdot 10^{23}\ \text{kg}\right)(85\,\text{l}}{\left(1.36 \cdot 10^{11}\ \text{m}\right)^2}$$

We can estimate the gravitational force exerted by the constellation Gemini by calculating the force exerted by its three brightest objects: Castor, Pollux, and Alhena (see Figure 12.8). Castor is a triple binary star system with a mass 6.0 times the mass of the Sun and is located a distance of 51.6 light-years from you. Pollux is a star with a mass 1.9 times the mass of the Sun, located 33.7 light-years away. Alhena is a binary star system with a mass 3.8 times the mass of the Sun, and it is 105 light-years away. The mass of the Sun is $2.0 \cdot 10^{30}\text{kg}$, and a light-year corresponds to $9.5 \cdot 10^{15}\text{m}$. The gravitational force exerted on you by the constellation Gemini is then

$$\begin{aligned} F_{\text{Gemini}} &= G\frac{M_{\text{Castor}}m}{r_{\text{Castor}}^2} + G\frac{M_{\text{Pollux}}m}{r_{\text{Pollux}}^2} + G\frac{M_{\text{Alhena}}m}{r_{\text{Alhena}}^2} = Gm\left(\frac{M_{\text{C}}}{r_{\text{C}}^2}\right. \\ &= \left(6.67 \cdot 10^{-11}\ \text{N}\,\text{m}^2/\text{kg}^2\right)(85\ \text{kg})\frac{2.0 \cdot 10^{30}\ \text{kg}}{\left(9.5 \cdot 10^{15}\ \text{m}\right)^2}\left(\frac{6.0}{(51.6)}\right. \\ &= 5.4 \cdot 10^{-13}\ \text{N}. \end{aligned}$$

The Moon exerts a very small but measurable force on you, whereas Mars and Gemini exert only negligible forces.

PROBLEM 2

When Mars and Earth are at their minimum separation distance, they are $r_{\text{M}} = 5.6 \cdot 10^{10}$ m apart. How far away from you does a truck of mass 16,000 kg have to be to have the same gravitational interaction with your body as Mars does at this minimum separation distance?

SOLUTION

If the two gravitational forces are equal in magnitude, we can write

$$G\frac{M_{\mathrm{M}}m}{r_{\mathrm{M}}^2} = G\frac{m_{\mathrm{T}}m}{r_{\mathrm{T}}^2},$$

where m is your mass, m_{T} is the mass of the truck, and r_{T} is the distance we want to find. Canceling out your mass and the universal gravitational constant and solving for r_{T}, we have

$$r_{\mathrm{T}} = r_{\mathrm{M}}\sqrt{\frac{m_{\mathrm{T}}}{M_{\mathrm{M}}}}.$$

Inserting the given numerical values leads to

$$r_{\mathrm{T}} = \left(5.6 \cdot 10^{10}\ \mathrm{m}\right)\sqrt{\frac{1.6 \cdot 10^{4}\ \mathrm{kg}}{6.4 \cdot 10^{23}\ \mathrm{kg}}} = 8.9\ \mathrm{m}.$$

This result means that if you get closer to the truck than 8.9 m, it exerts a bigger gravitational pull on you than does Mars at its closest approach.

12.2 Gravitation near the Surface of the Earth

Now we can use the general expression for the gravitational interaction between two masses to reconsider the gravitational force due to the Earth on an object near the surface of the Earth. We can neglect the gravitational interaction of this object with any other objects, because the magnitude of the gravitational interaction with Earth is many orders of magnitudes larger as a result of Earth's very large mass. Since we can represent an extended object by a point particle of the same mass located at the object's center of gravity, any object on the surface of Earth is experiencing a gravitational force directed toward the center of Earth. This direction is straight down anywhere on the surface of Earth, completely in accordance with empirical evidence.

It is more interesting to determine the magnitude of the gravitational force that an object experiences near the surface of the Earth. Inserting the mass of the Earth, M_{E}, as the mass of one object in equation 12.1 and expressing the altitude h above the surface of the Earth as $h + R_{\mathrm{E}} = r$, where R_{E} is the radius of the Earth, we find for this special case that

$$F = G\frac{M_{\mathrm{E}}m}{\left(R_{\mathrm{E}} + h\right)^2}. \tag{12.6}$$

Because $R_{\mathrm{E}} = 6370\,\mathrm{km}$, the altitude, h, of the object above the ground can be neglected for many applications. If we make this assumption, we find that $F = mg$, with

$$g = \frac{GM_{\mathrm{E}}}{R_{\mathrm{E}}^2} = \frac{\left(6.67 \cdot 10^{-11}\,\mathrm{m^3 kg^{-1} s^{-2}}\right)\left(5.97 \cdot 10^{24}\,\mathrm{kg}\right)}{\left(6.37 \cdot 10^{6}\mathrm{m}\right)^2} = 9.81\,\mathrm{m/}$$

As expected, near the surface of the Earth, the acceleration due to gravity can be approximated by the value of g that was introduced in Chapter 2. We can insert the mass and radius of other planets (see Table 12.1), moons, or stars into equation 12.7 and find their surface gravity as well. For example, the gravitational acceleration at the surface of the Sun is approximately 28 times larger than that at the surface of the Earth.

If we want to find g for altitudes where we cannot safely neglect h, we can start with equation 12.6, divide by the mass m to find the acceleration of that mass,

$$g(h) = \frac{GM_{\mathrm{E}}}{(R_{\mathrm{E}} + h)^2} = \frac{GM_{\mathrm{E}}}{R_{\mathrm{E}}^{2.}} = \left(1 + \frac{h}{R_{\mathrm{E}}}\right)^{-2} = g\left(1 + \frac{h}{R_{\mathrm{E}}}\right)^{2},$$

and then expand in powers of h/R_{E} to obtain, to the first order,

$$g(h) \approx g\left(1 - 2\frac{h}{R_{\mathrm{E}}} + \cdots\right). \qquad \textbf{(12.8)}$$

Equation 12.8 holds for all values of the altitude h that are small compared to the radius of Earth, and it implies that the gravitational acceleration falls off approximately linearly as a function of the altitude above ground. At the top of Mount Everest, the Earth's highest peak, at an altitude of 8850 m, the gravitational acceleration is reduced by 0.28%, or by less than $0.03\ \mathrm{m/s^2}$. The International Space Station is at an altitude of 365 km, where the gravitational acceleration is reduced by 11.5%, to a value of $8.7\ \mathrm{m/s^2}$. For higher altitudes, the linear approximation of equation 12.8 should definitely not be used.

However, to obtain a more precise determination of the gravitational acceleration, we need to consider other effects. First, the Earth is not an exact sphere; it has a slightly larger radius at the Equator than at the poles. (The value of 6371 km in Table 12.1 is the mean radius of Earth; the radius varies from 6357 km at the poles to 6378 km at the Equator.) Second, the density of Earth is not uniform, and for a precise determination of the gravitational acceleration, the density of the ground right below the measurement makes a difference. Third, and perhaps most important, there is a systematic variation (as a function of the polar angle θ; see Figure 12.9) of the apparent gravitational acceleration, due to the rotation of the Earth and the associated centripetal acceleration. From Chapter 9 on circular motion, we know that the centripetal acceleration is given by $a_{\mathrm{c}} = \omega^2\, r$, where r is the radius of the circular motion. For the rotation of the Earth, this radius is the perpendicular distance to the rotation axis. At the poles, this distance is zero, and there is no contribution from the centripetal acceleration. At the Equator, $r = R_{\mathrm{E}}$, and the maximum value for a_{c} is

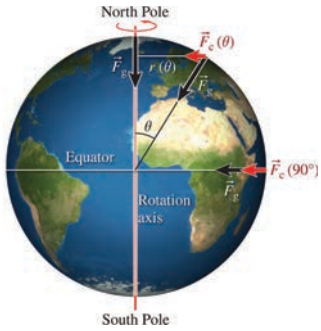

FIGURE 12.9 Variation of the effective force of gravity due to the Earth's rotation. (The lengths of the red arrows representing the centripetal force have been scaled up by a factor of 200 relative to the black arrows representing the gravitational force.)

$$a_{c,\,\max} = \omega^2 R_E = \left(7.29 \cdot 10^{-5}\,\mathrm{s}^{-1}\right)^2 (6378\,\mathrm{km}) = 0.034\,\mathrm{m/s}^2.$$

Thus, we find that the reduction of the apparent gravitational acceleration at the Equator due to the Earth's rotation is approximately equal to the reduction at the top of Mount Everest.

Self-Test Opportunity 12.2

What is the acceleration due to Earth's gravity at a distance $d = 3R_E$ from the center of the Earth, where R_E is the radius of the Earth?

EXAMPLE 12.2 Gravitational Tear from a Black Hole

A black hole is a very massive and extremely compact object that is so dense that light emitted from its surface cannot escape. (Thus, it appears black.)

PROBLEM

Suppose a black hole has a mass of $6.0 \cdot 10^{30}$ kg, three times the mass of the Sun. A spaceship of length $h = 85$ m approaches the black hole until the front of the ship is at a distance $R = 13{,}500$ km from the black hole. What is the difference in the acceleration due to gravity between the front and the back of the ship?

SOLUTION

We can determine the gravitational acceleration at the front of the spaceship due to the black hole via

$$g_{\text{bh}} = \frac{GM_{\text{bh}}}{R^2} = \frac{\left(6.67 \cdot 10^{-11}\ \text{m}^3\text{kg}^{-1}\text{s}^{-2}\right)\left(6.0 \cdot 10^{30}\ \text{kg}\right)}{\left(1.35 \cdot 10^{7}\ \text{m}\right)^2} = 2.2 \cdot 1$$

Now we can use the linear approximation of equation 12.8 to obtain

$$g_{\text{bh}}(h) - g_{\text{bh}}(0) = g_{\text{bh}}\left(1 - 2\frac{h}{R}\right) - g_{\text{bh}}(0) = -2g_{\text{bh}}\frac{h}{R},$$

where h is the length of the spaceship. Inserting the numerical values, we find the difference in the gravitational acceleration at the front and the back:

$$g_{\text{bh}}(h) - g_{\text{bh}}(0) = -2\left(2.2 \cdot 10^{6}\ \text{m/s}^2\right)\frac{85\ \text{m}}{1.35 \cdot 10^{7}\ \text{m}} = -27.7\ \text{m/s}^2$$

You can see that in the vicinity of the black hole, the differential acceleration between front and back is so large that the spaceship would have to have tremendous integral strength to avoid being torn apart!

(Near a black hole, Newton's Law of Gravity needs to be modified, but this example has ignored that change. In Section 35.8, we will discuss black holes in more detail and see why light is affected by the gravitational interaction.)

Concept Check 12.1

Why do the astronauts in the International Space Station experience weightlessness?

a) There is no air in outer space.

b) They are so far from the Earth that gravity is negligible.

c) The space station rotates at a high speed.

d) The space station is in free fall.

e) The space station has onboard antigravity devices.

12.3 Gravitation inside the Earth

Derivation 12.1 showed that the gravitational interaction of a mass m with a spherically symmetrical mass distribution (where m is located outside the sphere) is not affected if the sphere is replaced with a point particle with the same total mass, located at its center of mass (or center of gravity). Derivation 12.2 now shows that on the inside of a spherical shell of uniform density, the net gravitational force is zero.

DERIVATION 12.2 Force of Gravity inside a Hollow Sphere

We want to show that the gravitational force acting on a point mass inside a hollow homogeneous spherical shell is zero everywhere inside the shell. To do this, we could use calculus and a mathematical law known as Gauss's Law. (Gauss's Law, discussed in Chapter 22, applies to electrostatic interaction and the Coulomb force, which is another force that falls off with the inverse square of the distance between the interacting objects.) However, instead we'll use a geometrical argument that was presented by Newton in 1687 in his book *Philosophiae Naturalis Principia Mathematica,* usually known as the *Principia*.

Consider the (infinitesimally thin) spherical shell shown in Figure 12.10. We mark a point P at an arbitrary location inside the shell and then draw a straight line through this point. This straight line intersects the shell at two points, and the distances between those two intersection points and P are the radii r_1 and r_2. Now we draw cones with tips at P and with small opening angle θ around the straight line. The areas where the two cones intersect the shell are called A_1 and A_2. These areas depend on the angle θ, which is the same for both of them. Area A_1 is also proportional to r_1^2, and area A_2 is proportional to r_2^2, (see Figure 12.10b). Further, since the shell is homogeneous, the mass of any segment of it is proportional to the segment's area. Therefore, $m_1 = ar_1^2$ and $m_2 = ar_2^2$, with the same proportionality constant a.

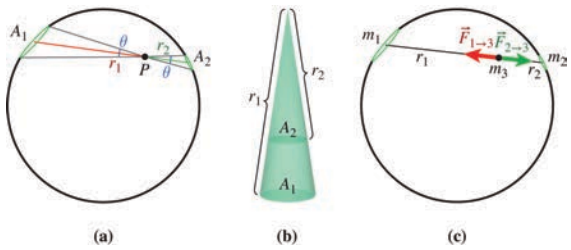

FIGURE 12.10 Gravitational interaction of a point with the surface of a hollow sphere: (a) cones from point *P* within the sphere to the sphere's surface; (b) details of the cones from *P* to the surface; (c) the balance of gravitational forces acting on *P* due to the opposite areas of the spherical shell.

The gravitational force $\overrightarrow{F}_{1\to 3}$ that the mass m_1 of area A_1 exerts on the mass m_3 at point *P* then points along r_1 toward the center of A_1. The gravitational force $\overrightarrow{F}_{2\to 3}$ acting on m_3 points in exactly the opposite direction along r_2. We can also find the magnitudes of these two forces:

$$F_{1\to 3} = \frac{Gm_1m_3}{r_1^2} = \frac{G\left(ar_1^2\right)m_3}{r_1^2} = Gam_3$$
$$F_{2\to 3} = \frac{Gm_2m_3}{r_2^2} = \frac{G\left(ar_2^2\right)m^3}{r_2^2} = Gam_3.$$

Since the dependence on the distance cancels out, the magnitudes of the two forces are the same. Since their magnitudes are the same, and their directions are opposite, the forces $\overrightarrow{F}_{1\to 3}$ and $\overrightarrow{F}_{2\to 3}$ exactly cancel each other (see Figure 12.10c).

Since the location of the point and the orientation of the line drawn through it were arbitrary, the result is true for any point inside the spherical shell. The entire shell can be accounted for with pairs of small opposite areas with no area left over. Thus, the net force of gravity acting on a point mass inside this spherical shell is indeed zero.

We can now gain physical insight into the gravitational force acting inside the Earth. Think of the Earth as composed of many concentric thin spherical shells. Then the gravitational force at a point *P* inside the Earth at a distance *r* from the center is due to those shells with a radius less than *r*. All shells with a greater radius do not contribute to the gravitational force on *P*. Furthermore, the mass, *M*(*r*), of all contributing shells can be imagined to be concentrated in the center, at a distance *r* away from *P*. The gravitational force acting on an object of mass *m* at a distance *r* from the center of the Earth is then

$$F(r) = G\frac{M(r)m}{r^2}. \qquad \textbf{(12.9)}$$

This is Newton's Law of Gravity (equation 12.1), with the mass of the contributing shells to be determined. In order to determine that mass, we

make the simplifying assumption of a constant density, ρ_E, inside Earth. Then we obtain

$$M(r) = \rho_{\mathrm{E}} V(r) = \rho_{\mathrm{E}} \tfrac{4}{3}\pi r^3. \qquad \textbf{(12.10)}$$

We can calculate the Earth's mass density from its total mass and radius:

$$\rho_{\mathrm{E}} = \frac{M_{\mathrm{E}}}{V_{\mathrm{E}}} = \frac{M_E}{\frac{4}{3}\pi R_{\mathrm{E}}^3} = \frac{\left(5.97 \cdot 10^{24}\,\mathrm{kg}\right)}{\frac{4}{3}\pi\left(6.37 \cdot 10^{6}\,\mathrm{m}\right)^3} = 5.5 \cdot 10^3\,\mathrm{kg/m^3}.$$

Substituting the expression for the mass from equation 12.10 into equation 12.9, we obtain an equation for the radial dependence of the gravitational force inside Earth:

$$F(r) = G\frac{M(r)m}{r^2} = G\frac{\rho_E \frac{4}{3}\pi r^3 m}{r^2} = \tfrac{4}{3}\pi G \rho_{\mathrm{E}} m r. \qquad \textbf{(12.11)}$$

Equation 12.11 states that the gravitational force increases linearly with the distance from the center of the Earth. In particular, if the point is located exactly at the center of the Earth, zero gravitational force acts on it.

Now we can compare the radial dependence of the gravitational acceleration divided by g (for an object acted on by just the force due to the Earth) inside and outside the Earth. Figure 12.11 shows the linear rise of this quantity inside the Earth, and the falloff in an inverse square fashion outside. At the surface of the Earth, these curves intersect, and the gravitational acceleration has the value of g. Also shown in the figure is the linear approximation (equation 12.8) to the dependence of the gravitational acceleration as a function of the height above the Earth's surface: $g(h) \approx g(1 - 2h/R_{\mathrm{E}} + \cdots) \Rightarrow g(r) \approx g(3 - 2r/R_{\mathrm{E}} + \cdots)$, because $r = h + R_{\mathrm{E}}$. You can clearly see that this approximation is valid to within a few percentage points for altitudes of a few hundred kilometers above the surface of the Earth.

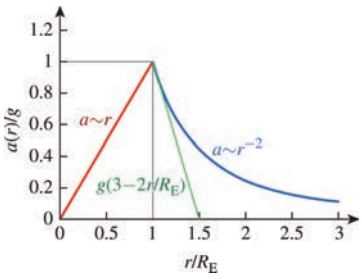

FIGURE 12.11
Dependence of the gravitational acceleration on the radial distance from the center of the Earth.

Note that the functional form of the force in equation 12.11 is that of a spring force, with a restoring force that increases linearly as a function of displacement from equilibrium at $r = 0$. Equation 12.11 specifies the magnitude of the gravitational force. Because the force always points toward the center of the Earth, we can also write equation 12.11 as a one-dimensional vector equation in terms of x, the displacement from equilibrium:

$$F_x(x) = -\tfrac{4}{3}\pi G\rho_{\mathrm{E}} m x = -\frac{mg}{R_{\mathrm{E}}}x = -kx.$$

Concept Check 12.2

The Moon can be considered as a sphere of uniform density with mass M_{M} and radius R_{M}. At the center of the Moon, the magnitude of the gravitational force acting on a mass m due to the mass of the Moon is

a) $mGM_{\mathrm{M}}/R_{\mathrm{M}}^2$.

b) $\frac{1}{2}mGM_{\mathrm{M}}/R_{\mathrm{M}}^2$.

c) $\frac{3}{5}mGM_{\mathrm{M}}/R_{\mathrm{M}}^2$.

d) zero.

e) $2mGM_{\mathrm{M}}/R_{\mathrm{M}}^2$.

This result is Hooke's Law for a spring, which we encountered in Chapter 5. Therefore, the "spring constant" of the gravitational force is

$$k = \tfrac{4}{3}\pi G\rho_{\mathrm{E}}m = \frac{mg}{R_{\mathrm{E}}}.$$

Similar considerations also apply to the gravitational force inside other spherically symmetrical mass distributions, such as planets or stars.

12.4 Gravitational Potential Energy

In Chapter 6, we saw that the gravitational potential energy is given by $U = mgh$, where h is the distance in the y-direction, provided the gravitational force is written $\vec{F} = -mg\hat{y}$ (with the sign convention that positive is straight up). Using Newton's Law of Gravity, we can obtain a more general expression for gravitational potential energy. Integrating equation 12.1 yields an expression for the gravitational potential energy of a system of two masses m_1 and m_2 separated by a distance r:

$$U(r) - U(\infty) = -\int_{\infty}^{r} \vec{F}\left(\vec{r}\right) \cdot d\vec{r} = \int_{\infty}^{r} F\left(r'\right) dr' = \int_{\infty}^{r} G\frac{m_1 m_2}{r'^2} dr'$$

$$= Gm_1 m_2 \int_{\infty}^{r} \frac{1}{r'^2} dr' = -Gm_1 m_2 \frac{1}{r'}\Big|_{\infty}^{r} = -G\frac{m_1 m_2}{r}.$$

The first part of this equation is the general relation between force and potential energy. For a gravitational interaction, the force depends only on the radial separation, $\vec{F}\left(\vec{r}\right) = \vec{F}(r)$, and is always attractive, $\vec{F}(r) = -F(r)\hat{r}$. Therefore $\vec{F}\left(\vec{r}\right) \cdot d\vec{r} = -F(r)dr$, which was used in the second part of this equation.

Note that the equation describing gravitational potential energy only tells us the *difference* between the gravitational potential energy at separation r and at separation infinity. We set $U(\infty) = 0$, which implies that the gravitational potential energy vanishes between two objects that are separated by an infinite distance. This choice gives us the following expression for the **gravitational potential energy** as a function of the separation of two masses:

$$U(r) = -G\frac{m_1 m_2}{r}. \qquad \textbf{(12.12)}$$

Note that the gravitational potential energy is always less than zero with $U(\infty) = 0$. This dependence of the gravitational potential energy on $1/r$ is

illustrated by the red curve in Figure 12.12 for an arbitrary mass near the surface of the Earth.

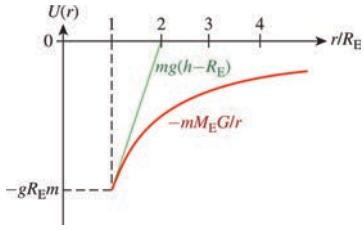

FIGURE 12.12
Dependence of the gravitational potential energy on the distance to the center of the Earth, for distances larger than the radius of the Earth. The red curve represents the exact expression; the green line represents the linear approximation for values of *r* not much larger than the radius of the Earth, R_E.

For interactions among more than two objects, we can write all pairwise interactions between two of them and integrate. The gravitational potential energies from these interactions are simply added to give the total gravitational potential energy. For three point particles, we find, for example,

$$U = U_{12} + U_{13} + U_{23} = -G\frac{m_1 m_2}{\left|\vec{r}_1 - \vec{r}_2\right|} - G\frac{m_1 m_3}{\left|\vec{r}_1 - \vec{r}_3\right|} - G\frac{m_2 m_3}{\left|\vec{r}_2 - \vec{r}_3\right|}.$$

An important special case occurs when one of the two interacting objects is the Earth. For altitudes *h* that are small compared to the radius of the Earth, we expect to repeat the previous result that the gravitational potential energy is *mgh*. Because the Earth is many orders of magnitude more massive than any object on the surface of the Earth for which we might want to calculate the gravitational potential energy, the combined center of mass of the Earth and the object is practically identical to the center of mass of the

Earth, which we then select as the origin of the coordinate system. Using equation 12.12, this results in

$$\begin{aligned} U(h) = & -G\frac{M_{\mathrm{E}}m}{R_{\mathrm{E}}+h} = -G\frac{M_{\mathrm{E}}m}{R_{\mathrm{E}}}\left(1+\frac{h}{R_{\mathrm{E}}}\right)^{-1} \\ & \approx -\frac{\mathrm{G}M_{\mathrm{E}}m}{R_{\mathrm{E}}} + \frac{\mathrm{G}M_{\mathrm{E}}m}{R_{\mathrm{E}}^2}h = -gmR_{\mathrm{E}} + mgh. \end{aligned}$$

In the second step here, we used the fact that $h \ll R_{\mathrm{E}}$ and expanded. This result (plotted in green in Figure 12.12) looks almost like the expression $U = mgh$ from Chapter 6, except for the addition of the constant term $-gmR_{\mathrm{E}}$. This constant term is a result of the choice of the integration constant in equation 12.12. However, as was stressed in Chapter 6, we can add any additive constant to the expression for potential energy without changing the physical results for the motion of objects. The only physically relevant quantity is the difference in potential energy between two different locations. Taking the difference between altitude h and altitude zero results in

$$\Delta U = U(h) - U(0) = (-gmR_{\mathrm{E}} + mgh) - (-gmR_3) = mgh.$$

As expected, the additive constant $-gmR_{\mathrm{E}}$ cancels out, and we obtain the same result for low altitudes, h, that we had previously derived: $\Delta U = mgh$.

Escape Speed

With an expression for the gravitational potential energy, we can determine the total mechanical energy for a system consisting of an object of mass m_1 and speed v_1, that has a gravitational interaction with another object of mass m_2 and speed v_2, if the two objects are separated by a distance $r = \left|\overrightarrow{r_1} - \overrightarrow{r_2}\right|$:

$$E = K + U = \tfrac{1}{2}m_1 v_1^2 + \tfrac{1}{2}m_2 v_2^2 - \frac{G m_1 m_2}{\left|\overrightarrow{r_1} - \overrightarrow{r_2}\right|}. \qquad \textbf{(12.13)}$$

Of particular interest is the case where one of the objects is the Earth ($m_1 \equiv M_\mathrm{E}$). If we consider the reference frame to be that of the Earth ($v_1 = 0$), the Earth has no kinetic energy in this frame. Again, we put the origin of the coordinate system at the center of the Earth. Then the expression for the total energy of this system is just the kinetic energy of object 2 (but we have omitted the subscript 2), plus the gravitational potential energy:

$$E = \tfrac{1}{2}mv^2 - \frac{GM_\mathrm{E}m}{R_\mathrm{E} + h},$$

where, as before, h is the altitude above Earth's surface of the object with mass m.

If we want to find out what initial speed a projectile must have to escape to an infinite distance from Earth, called the **escape speed,** v_E (where E stands for Earth), we can use energy conservation. At infinite separation, the gravitational potential energy is zero, and the minimum kinetic energy is also zero. Thus, the minimum total energy with which a projectile can escape from the Earth's gravitational influence is zero. Energy conservation then implies, starting from the Earth's surface:

$$E(h = 0) = \tfrac{1}{2}mv_\mathrm{E}^2 - \frac{GM_\mathrm{E}m}{R_\mathrm{E}} = 0.$$

Solving this for v_E gives an expression for the minimum escape speed:

$$v_\mathrm{E} = \sqrt{\frac{2GM_\mathrm{E}}{R_\mathrm{E}}}. \qquad \textbf{(12.14)}$$

Inserting the numerical values of these constants, we finally obtain

$$v_{\mathrm{E}} = \sqrt{\frac{2\left(6.67 \cdot 10^{-11}\ \mathrm{m^3 kg^{-1}\ s^{-2}}\right)\left(5.97 \cdot 10^{24}\ \mathrm{kg}\right)}{6.37 \cdot 10^{6}\ \mathrm{m}}} = 11.2\ \mathrm{km/s}.$$

This escape speed is approximately equal to 25,000 mph. The same calculation can also be performed for other planets, moons, and stars by inserting the relevant constants (for example, see Table 12.1).

Concept Check 12.3

The escape speed from the surface of the Moon $\left(\text{mass} = 7.35 \cdot 10^{22}\ \text{kg and diameter} = 3476\ \text{km}\right)$ is

a) $2.38\ \mathrm{km/s}$.

b) $1.68\ \mathrm{km/s}$.

c) $11.2\ \mathrm{km/s}$.

d) $5.41\ \mathrm{km/s}$.

Note that the angle with which the projectile is launched into space does not enter into the expression for the escape speed. Therefore, it does not matter if the projectile is shot straight up or almost in a horizontal direction. However, we neglected air resistance, and the launch angle would make a difference if we accounted for its effect. An even bigger effect results from the Earth's rotation. Since the Earth rotates once around its axis each day, a point on the surface of the Earth located at the Equator has a speed of $v = 2\pi R_{\mathrm{E}}/(1\ \mathrm{day}) \approx 0.46\ \mathrm{km/s}$, which decreases to zero at the poles. The direction of the corresponding velocity vector points east, tangentially to the Earth's surface. Therefore, the launch angle matters most at the Equator. For a projectile fired in the eastern direction from any location on the Equator, the escape speed is reduced to approximately $10.7\ \mathrm{km/s}$.

Can a projectile launched from the surface of the Earth with a speed of $11.2\ \mathrm{km/s}$ escape the Solar System? Doesn't the gravitational potential energy of the projectile due to its interaction with the Sun play a role? At first glance, it would appear not. After all, the gravitational force the Sun exerts on an object located near the surface of the Earth is negligible compared to

the force the Earth exerts on that object. As proof, consider that if you jump up in the air, you land at the same place, independent of what time of day it is, that is, where the Sun is in the sky. Thus, we can indeed neglect the Sun's gravitational force near the surface of the Earth.

However, the gravitational force is far different from the gravitational potential energy. In contrast to the force, which falls off as r^{-2}, the potential energy falls off much more slowly, as it is proportional to r^{-1}. It is straightforward to generalize equation 12.14 for the escape speed from any planet or star with mass *M*, if the object is initially separated a distance *R* from the center of that planet or star:

$$v = \sqrt{\frac{2GM}{R}}. \qquad \textbf{(12.15)}$$

Inserting the mass of the Sun and the size of the orbit of the Earth we find v_{S}, the speed needed for an object to escape from the gravitational influence of the Sun if it is initially a distance from it equal to the radius of the Earth's orbit:

$$v_{\mathrm{S}} = \sqrt{\frac{2\left(6.67 \cdot 10^{-11}\ \mathrm{m^3 kg^{-1} s^{-2}}\right)\left(1.99 \cdot 10^{30}\ \mathrm{kg}\right)}{1.50 \cdot 10^{11}\ \mathrm{m}}} = 42\ \mathrm{km/s}.$$

This is quite an astonishing result: The escape speed needed to leave the Solar System from the orbit of the Earth is almost four times larger than the escape speed needed to get away from the gravitational attraction of the Earth.

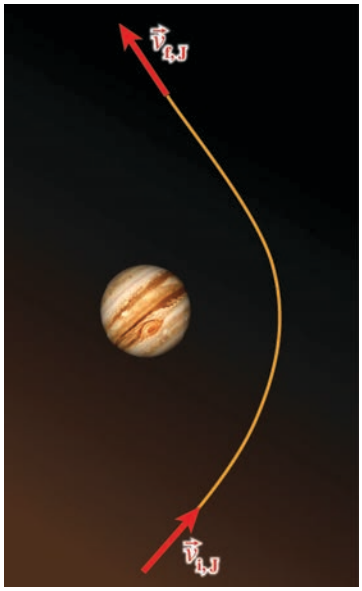
Launching a projectile from the surface of the Earth with enough speed to leave the Solar System requires overcoming the combined gravitational potential energy of the Earth and the Sun. Because the two potential energies add, the combined escape speed is

$$v_{\mathrm{ES}} = \sqrt{v_{\mathrm{E}}^2 + v_{\mathrm{S}}^2} = 43.5\ \mathrm{km/s}.$$

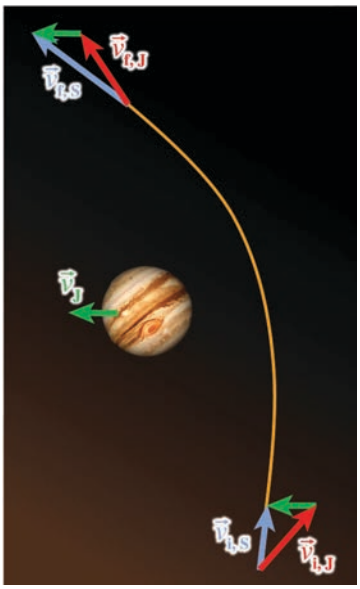
We found that the rotation of the Earth has a nonnegligible, but still small, effect on the escape speed. However, a much bigger effect arises from the orbital motion of the Earth around the Sun. The Earth orbits the Sun with an orbital speed of $v_{\mathrm{O}} = 2\pi R_{\mathrm{ES}}/(1\ \mathrm{yr}) = 29.8\ \mathrm{km/s}$, where R_{ES} is the distance between Earth and Sun (149.6, or approximately 150, million km, according to Table 12.1). A projectile launched in the direction of this orbital velocity vector needs a launch velocity of only $v_{\mathrm{ES,min}} = (43.5 - 29.8)\ \mathrm{km/s} = 13.7\ \mathrm{km/s}$, whereas one launched in the

opposite direction must have $v_{\mathrm{ES,max}} = (43.5 + 29.8)\,\mathrm{km/s} = 73.3\,\mathrm{km/s}$. Other launch angles produce all values between these two extremes.

When NASA launches a probe to explore the outer planets or to leave the Solar System—for example, *Voyager 2*—the gravity assist technique is used to lower the required launch velocity. This technique is illustrated in Figure 12.13. Part (a) is a sketch of a flyby of Jupiter as seen by an observer at rest relative to Jupiter. Notice that the velocity vector of the spacecraft changes direction but has the same length at the same distance from Jupiter as the spacecraft approaches and as it leaves. This is a consequence of energy conservation. Figure 12.13b is a sketch of the spacecraft's trajectory as seen by an observer at rest relative to the Sun. In this reference frame, Jupiter moves with an orbital velocity of approximately 13 km/s. To transform from Jupiter's reference frame to the Sun's reference frame, we have to add the velocity of Jupiter to the velocities observed in Jupiter's frame (red arrows) to obtain the velocities in the Sun's frame (blue arrows). As you can see from the figure, in the Sun's frame, the length of the final velocity vector is significantly greater than that of the initial velocity vector. This means that the spacecraft has acquired significant additional kinetic energy (and Jupiter has lost this kinetic energy) during the flyby, allowing it to continue escaping the gravitational pull of the Sun.



(a)



(b)

EXAMPLE 12.3 Asteroid Impact

One of the most likely causes of the extinction of dinosaurs at the end of the Cretaceous period, about 65 million years ago, was a large asteroid hitting the Earth. Let's look at the energy released during an asteroid impact.

PROBLEM

Suppose a spherical asteroid, with a radius of 1.00 km and a mass density of $4750\ \mathrm{kg/m^3}$, enters the Solar System with negligible speed and then collides with Earth in such a way that it hits Earth from a radial direction with respect to the Sun. What kinetic energy will this asteroid have in the Earth's reference frame just before its impact on Earth?

SOLUTION

First, we calculate the mass of the asteroid:

$$m_\mathrm{a} = V_\mathrm{a}\rho_\mathrm{a} = \tfrac{4}{3}\pi r_\mathrm{a}^3\rho_\mathrm{a} = \tfrac{4}{3}\pi\left(1.00\cdot10^3\ \mathrm{m}\right)^3\left(4750\ \mathrm{kg/m^3}\right) = 1.99$$

If the asteroid hits the Earth in a radial direction with respect to the Sun, the Earth's velocity vector will be perpendicular to that of the asteroid at impact, because the Earth moves tangentially around the Sun. Thus, there are three contributions to the kinetic energy of the asteroid as measured in Earth's reference frame: (1) conversion of the gravitational potential energy between Earth and asteroid, (2) conversion of the gravitational potential energy between Sun and asteroid, and (3) kinetic energy of the Earth's motion relative to that of the asteroid.

Because we have already calculated the escape speeds corresponding to the two gravitational potential energy terms and because the asteroid will arrive with the kinetic energy that corresponds to these escape speeds, we can simply write

$$K = \tfrac{1}{2}m_\mathrm{a}\left(v_\mathrm{E}^2 + v_\mathrm{S}^2 + v_\mathrm{O}^2\right).$$

Now we insert the numerical values:

$$\begin{aligned} K &= 0.5\left(1.99\cdot10^{13}\ \mathrm{kg}\right)\left[\left(1.1\cdot10^4\ \mathrm{m/s}\right)^2 + \left(4.2\cdot10^4\ \mathrm{m/s}\right)^2 + \left(3.\right.\right. \\ &= 2.8\cdot10^{22}\ \mathrm{J}. \end{aligned}$$

This value is equivalent to the energy released by approximately 300 million nuclear weapons of the magnitude of those used to destroy Hiroshima and Nagasaki in World War II. You can begin to understand the destructive power of an asteroid impact of this magnitude—an event like this could wipe out human life on Earth. A somewhat bigger asteroid, with a diameter of 6 to 10 km, hit Earth near the tip of the Yucatan peninsula in the Gulf of Mexico approximately 65 million years ago. It is believed to be responsible for the K-T (Cretaceous-Tertiary) extinction, which killed off the dinosaurs.

DISCUSSION

Figure 12.14 shows the approximately 1.5 km in diameter and almost 200 m deep Barringer impact crater, which was formed approximately 50,000 years ago when a meteorite of approximately 50-m diameter, with a mass of approximately 300,000 tons $\left(3 \cdot 10^8 \text{ kg}\right)$, hit Earth with a speed of approximately 12 km/s. This was a much smaller object than the asteroid described in this example, but the impact still had the destructive power of 250 atomic bombs of the Hiroshima/Nagasaki class.

Gravitational Potential

Equation 12.12 states that the gravitational potential energy of any object is proportional to that object's mass. When we employed energy conservation to calculate the escape speed, we saw that the mass of the object canceled out, because both kinetic energy and gravitational potential energy are proportional to an object's mass. Thus, the kinematics are independent of the object's mass. For example, let's consider the gravitational potential energy of a mass m interacting with Earth, $U_{\mathrm{E}}(r) = -GM_{\mathrm{E}}m/r$. The Earth's gravitational potential $V_{\mathrm{E}}(r)$ is defined as the ratio of the gravitational potential energy to the mass of the object, $V_{\mathrm{E}}(r) = U_{\mathrm{E}}(r)/m$, or

$$V_{\mathrm{E}}(r) = -\frac{GM_{\mathrm{E}}}{r}. \qquad \textbf{(12.16)}$$

This definition has the advantage of giving information on the gravitational interaction with Earth, independently of the other mass involved. (We will explore the concept of potentials in much more depth in Chapter 23 on electric potentials.)

SOLVED PROBLEM 12.1 Astronaut on a Small Moon

PROBLEM

A small spherical moon has a radius of $6.30 \cdot 10^4$ m and a mass of $8.00 \cdot 10^{18}$ kg. An astronaut standing on the surface of the moon throws a rock straight up. The rock reaches a maximum height of 2.20 km above the surface of the moon before it returns to the surface. What was the initial speed of the rock as it left the hand of the astronaut? (This moon is too small to have an atmosphere.)

SOLUTION

THINK

We know the mass and radius of the moon, allowing us to compute the gravitational potential. Knowing the height that the rock attains, we can use energy conservation to calculate the initial speed of the rock.

SKETCH

Figure 12.15 is a sketch showing the rock at its highest point.

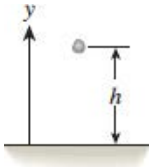

FIGURE 12.15 The rock at the highest point on its straight-line trajectory.

RESEARCH

We denote the mass of the rock as m, the mass of the moon as m_{moon}, and the radius of the moon as R_{moon}. The potential energy of the rock on the surface of the moon is then

$$U(R_{\text{moon}}) = -G\frac{m_{\text{moon}}}{R_{\text{moon}}}m. \qquad \text{(i)}$$

The potential energy at the top of the rock's trajectory is

$$U(R_{\text{moon}} + h) = -G\frac{m_{\text{moon}}}{R_{\text{moon}} + h}m. \qquad \text{(ii)}$$

The kinetic energy of the rock as it leaves the hand of the astronaut depends on its mass and the initial speed v:

$$K(R_{\text{moon}}) = \tfrac{1}{2}mv^2. \qquad \text{(iii)}$$

At the top of the rock's trajectory, $K(R_{\text{moon}} + h) = 0$. Conservation of total energy now helps us solve the problem:

$$U(R_{\text{moon}}) + K(R_{\text{moon}}) = U(R_{\text{moon}} + h) + K(R_{\text{moon}} + h). \qquad \text{(iv)}$$

SIMPLIFY

We substitute the expressions from equations (i) through (iii) into (iv):

$$\begin{gathered} -G\frac{m_{\text{moon}}}{R_{\text{moon}}}m + \tfrac{1}{2}mv^2 = -G\frac{m_{\text{moon}}}{R_{\text{moon}} + h}m + 0 \Rightarrow \\ -G\frac{m_{\text{moon}}}{R_{\text{moon}}} + \tfrac{1}{2}v^2 = -G\frac{m_{\text{moon}}}{R_{\text{moon}} + h} \Rightarrow \\ v = \sqrt{2Gm_{\text{moon}}\left(\frac{1}{R_{\text{moon}}} - \frac{1}{R_{\text{moon}} + h}\right)}. \end{gathered}$$

CALCULATE

Putting in the numerical values, we get

$$\begin{aligned} v &= \sqrt{2\left(6.67 \cdot 10^{-11}\ \text{N m}^2/\text{kg}^2\right)\left(8.00 \cdot 10^{18}\ \text{kg}\right)\left(\frac{1}{6.30 \cdot 10^4\ \text{m}} - \right.} \\ &= 23.9078\ \text{m/s}. \end{aligned}$$

ROUND

Rounding to three significant figures gives

$$v = 23.9\ \mathrm{m/s}.$$

DOUBLE-CHECK

To double-check our result, let's make the simplifying assumption that the force of gravity on the small moon does not change with altitude. We can find the initial speed of the rock using conservation of energy:

$$mg_{\mathrm{moon}}h = \tfrac{1}{2}mv^2, \qquad \text{(v)}$$

where h is the height attained by the rock, v is the initial speed, m is the mass of the rock, and g_{moon} is the acceleration due to gravity at the surface of the small moon. The acceleration due to gravity is

$$g_{\mathrm{moon}} = G\frac{m_{\mathrm{moon}}}{R_{\mathrm{moon}}^2} = \left(6.67 \cdot 10^{-11}\ \mathrm{N\,m^2/kg^2}\right)\frac{8.00 \cdot 10^{18}\ \mathrm{kg}}{\left(6.30 \cdot 10^{4}\ \mathrm{m}\right)^2} = 0.$$

Solving equation (v) for the initial speed of the rock gives us

$$v = \sqrt{2g_{\mathrm{moon}}h}.$$

Putting in the numerical values, we get

$$v = \sqrt{2\left(0.134\ \mathrm{m/s^2}\right)(2200\ \mathrm{m})} = 24.3\ \mathrm{m/s}.$$

This result is close to but larger than our answer, $23.9\ \mathrm{m/s}$. The fact that the simple assumption of constant gravitational force leads to a larger initial speed than found for the realistic case where the force decreases with altitude makes sense. The close agreement of the two results also makes sense because the altitude gained (2.20 km) is not too large compared to the radius of the small moon (63.0 km). Thus, our answer seems reasonable.

12.5 Kepler's Laws and Planetary Motion

Johannes Kepler (1571–1630) used empirical observations, mainly from data gathered by Tycho Brahe, and sophisticated calculations to arrive at the famous **Kepler's laws of planetary motion,** published in 1609 and 1619. These laws were published decades before the birth, in 1643, of Isaac Newton, whose law of gravitation would eventually show *why* Kepler's laws were true. What is particularly significant about Kepler's laws is that they challenged the prevailing worldview at the time, with the Earth in the center of the universe (a geocentric theory) and the Sun and all the planets and stars orbiting around it, just as the Moon does. Kepler and other pioneers, particularly Nicolaus Copernicus and Galileo Galilei, changed this geocentric view into a heliocentric (Sun-centered) cosmology. Today, space probes have provided direct observations from vantage points outside the Earth's atmosphere and verified that Copernicus, Kepler, and Galilei were correct. However, the simplicity with which the heliocentric model was able to explain astronomical observations won intelligent people over to their view long before external observations were possible.

Kepler's First Law: Orbits

All planets move in elliptical orbits with the Sun at one focal point.

An *ellipse* is a closed curve in a two-dimensional plane. It has two focal points, f_1 and f_2, separated by a distance $2c$ (Figure 12.16). For each point on an ellipse, the sum of the distances to the two focal points is a constant:

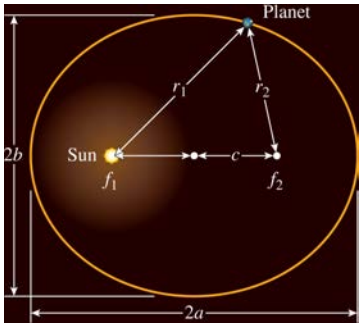

FIGURE 12.16
Parameters used in describing ellipses and elliptical orbits.

$$r_1 + r_2 = 2a.$$

The length a is called the semimajor axis of the ellipse (see Figure 12.16). (*Note:* Unfortunately, the standard notation for the semimajor axis of an ellipse uses the same letter, a, as is conventionally used to symbolize acceleration. You should be careful to avoid confusion.) The semiminor axis, b, is related to a and c via

$$b^2 \equiv a^2 - c^2.$$

In terms of the Cartesian coordinates x and y, the points on the ellipse satisfy the equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

where the origin of the coordinate system is at the center of the ellipse. If $a = b$, a circle (a special case of an ellipse) results.

It is useful to introduce the eccentricity, e, of an ellipse, defined as

$$e = \frac{c}{a} = \sqrt{1 - \frac{b^2}{a^2}}.$$

An eccentricity of zero, the smallest possible value, characterizes a circle. The ellipse shown in Figure 12.16 has an eccentricity of 0.5. The eccentricity of the Earth's orbit around the Sun is only 0.017. If you were to plot an ellipse with this value of *e*, you could not distinguish it from a circle by visual inspection. The length of the semiminor axis of Earth's orbit is approximately 99.98% of the length of the semimajor axis. At its closest approach to the Sun, called the *perihelion*, the Earth is 147.1 million km away from the Sun. The *aphelion*, which is the farthest point from the Sun in Earth's orbit, is 152.1 million km.

It is important to note that the change in seasons is *not* caused primarily by the eccentricity of the Earth's orbit. (The point of closest approach to the Sun is reached in early January each year, in the middle of the cold season in the Northern Hemisphere.) Instead, the seasons are caused by the fact that the Earth's axis of rotation is tilted by an angle of 23.4° relative to the plane of the orbital ellipse. This tilt exposes the Northern Hemisphere to the Sun's rays for longer periods and at a more direct angle in the summer months.

Among the other planetary orbits, Mercury's has the largest eccentricity, 0.206. (Pluto's orbital eccentricity is even larger, at 0.249, but Pluto has been declassified as a planet since August 2006.) Venus's orbit has the smallest eccentricity, 0.007, followed by Neptune with an eccentricity of 0.009.

Kepler’s Second Law: Areas

A straight line connecting the center of the Sun and the center of any planet (Figure 12.17) sweeps out an equal area in any given time interval:

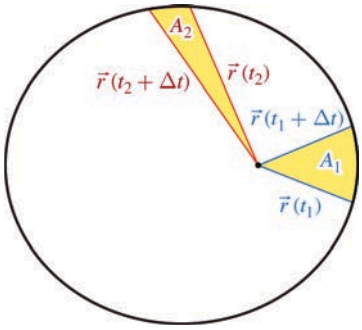

FIGURE 12.17
Kepler’s Second Law states that equal areas are swept out in equal time periods, or

$$A_1 = A_2.$$

$$\frac{dA}{dt} = \text{constant}. \qquad \textbf{(12.17)}$$

Kepler’s Third Law: Periods

The square of the period of a planet’s orbit is proportional to the cube of the semimajor axis of the orbit:

$$\frac{T^2}{a^3} = \text{constant}. \tag{12.18}$$

This proportionality constant can be expressed in terms of the mass of the Sun and the universal gravitational constant

$$\frac{T^2}{a^3} = \frac{4\pi^2}{GM}. \tag{12.19}$$

DERIVATION 12.3 Kepler's Laws

The general proof of Kepler's laws uses Newton's Law of Gravity, equation 12.1, and the law of conservation of angular momentum. With quite a bit of algebra and calculus, it is then possible to prove all three of Kepler's laws. Here we will derive Kepler's Second and Third Laws for circular orbits with the Sun in the center, allowing us to put the Sun at the origin of the coordinate system and neglect the motion of the Sun around the common center of mass of the Sun-planet system.

First, we show that circular motion is indeed possible. From Chapter 9, we know that in order to obtain a closed circular orbit, the centripetal force needs to be equal to the gravitational force:

$$m\frac{v^2}{r} = G\frac{Mm}{r^2} \Rightarrow v = \sqrt{\frac{\mathrm{GM}}{r}}.$$

This result establishes two important facts: First, the mass of the orbiting object has canceled out, so all objects can have the same orbit, provided that their mass is small compared to the Sun. Second, any given orbital radius, r, has a unique orbital velocity corresponding to it. Also, for a given orbital radius, we obtain a constant value of the angular velocity:

$$\omega = \frac{v}{r} = \sqrt{\frac{GM}{r^3}}. \qquad \text{(i)}$$

Next, we examine the area swept out by a radial vector connecting the Sun and the planet. As indicated in Figure 12.18, the area swept out is $dA = \frac{1}{2}rs = \frac{1}{2}r^2 d\theta$. Taking the time derivative results in

$$\frac{dA}{dt} = \frac{1}{2}r^2\frac{d\theta}{dt} = \frac{1}{2}r^2\omega.$$

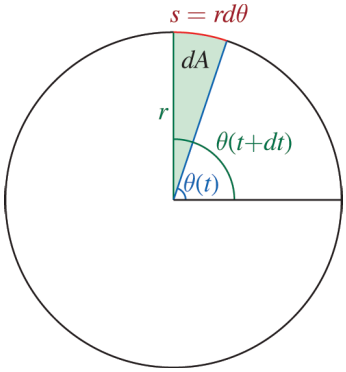

FIGURE 12.18 Angle, arc length, and area as a function of time.

Because, for a given orbit, ω and r are constant, we have derived Kepler's Second Law, which states that $dA/dt = \text{constant}$.

Finally, for Kepler's Third Law, we use $T = 2\pi/\omega$ and substitute the expression for the angular velocity from equation (i). This results in

$$T = 2\pi\sqrt{\frac{r^3}{GM}}.$$

We can rearrange this equation and obtain

$$\frac{T^2}{r^3} = \frac{4\pi^2}{GM}.$$

This proves Kepler's Third Law and gives the value for the proportionality constant between the square of the orbital period and the cube of the orbital radius.

Again, keep in mind that Kepler's laws are valid for elliptic orbits in general, not just for circular orbits. Instead of referring to the radius of the circle, r has to be taken as the semimajor axis of the ellipse for such orbits. Perhaps an even more useful formulation of Kepler's Third Law may be written as

$$\frac{T_1^2}{a_1^3} = \frac{T_2^2}{a_2^3}. \tag{12.20}$$

With this formula, we can easily find orbital periods and radii for two different orbiting objects.

SOLVED PROBLEM 12.2 Orbital Period of Sedna

PROBLEM

On November 14, 2003, astronomers discovered a previously unknown object in part of the Kuiper Belt beyond the orbit of Neptune. They named this object Sedna, after the Inuit goddess of the sea. The average distance of Sedna from the Sun is $77.6 \cdot 10^9$ km. How long does it take Sedna to complete one orbit around the Sun?

SOLUTION

THINK

We can use Kepler's laws to relate Sedna's distance from the Sun to the period of Sedna's orbit around the Sun.

SKETCH

A sketch comparing the average distance of Sedna from the Sun with the average distance of Pluto from the Sun is shown in Figure 12.19.

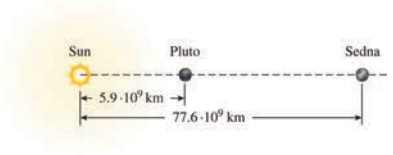

FIGURE 12.19 The distance of Sedna from the Sun compared with the distance of Pluto from the Sun.

RESEARCH

We can relate the orbit of Sedna to the known orbit of the Earth using equation 12.20 (a form of Kepler's Third Law):

$$\frac{T_{\text{Earth}}^2}{a_{\text{Earth}}^3} = \frac{T_{\text{Sedna}}^2}{a_{\text{Sedna}}^3}, \qquad \text{(i)}$$

where T_{Earth} is the period of Earth's orbit, a_{Earth} is the radius of Earth's orbit, T_{Sedna} is the period of Sedna's orbit, and a_{Sedna} is the radius of

Sedna's orbit.

SIMPLIFY

We can solve equation (i) for the period of Sedna's orbit:

$$T_{\text{Sedna}} = T_{\text{Earth}} \left(\frac{a_{\text{Sedna}}}{a_{\text{Earth}}} \right)^{3/2}.$$

CALCULATE

Putting in the numerical values, we get

$$T_{\text{Sedna}} = 1(\text{yr}) \left(\frac{77.6 \cdot 10^9 \text{ km}}{0.150 \cdot 10^9 \text{ km}} \right)^{3/2} = 12,018 \text{ yr}.$$

ROUND

We report our result to two significant figures:

$$T_{\text{Sedna}} = 1.18 \cdot 10^4 \text{ yr}.$$

DOUBLE-CHECK

We can compare our result for Sedna with the measured values for the semimajor axes of the orbits and orbital periods of the planets and several dwarf planets. As Figure 12.20 shows, our calculated result (dashed line, representing Kepler's Third Law) fits well with the extrapolation of the data from the planets (red dots) and dwarf planets (blue dots).

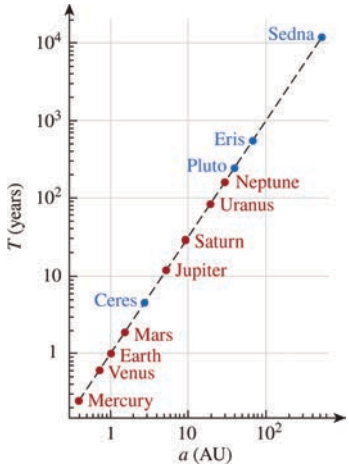

FIGURE 12.20
Orbital period versus length of the semimajor axis for orbits of objects in the Solar System.

We can also use Kepler's Third Law to determine the mass of the Sun. We obtain this result by solving equation 12.19 for the mass of the Sun:

$$M = \frac{4\pi^2 a^3}{GT^2}. \qquad \textbf{(12.21)}$$

Inserting the data for Earth's orbital period and radius gives

$$M = \frac{4\pi^2 \left(1.496 \cdot 10^{11}\ \text{m}\right)^3}{\left(6.67 \cdot 10^{-11}\ \text{m}^3\text{kg}^{-1}\text{s}^{-2}\right)\left(3.16 \cdot 10^{7}\ \text{s}\right)^2} = 1.98 \cdot 10^{30}\ \text{kg}.$$

Self-Test Opportunity 12.3

Use the fact that the gravitational interaction between Earth and Sun provides the centripetal force that keeps Earth on its orbit to confirm equation 12.21. (Assume a circular orbit.)

It is also possible to use Kepler's Third Law to determine the mass of the Earth from the period and radius of the Moon's orbit around Earth. In fact,

astronomers can use this law to determine the mass of any astronomical object that has a satellite orbiting it if they know the radius and period of the orbit.

EXAMPLE 12.4 Black Hole at the Center of the Milky Way

PROBLEM

Over the past 25 years, astronomers have measured the positions of stars orbiting near the massive black hole at the center of our Milky Way galaxy. This work led to the 2020 Nobel Prize in Physics for Andrea Ghez and Reinhard Genzel, together with Roger Penrose. Figure 12.21 shows measurements of the position of nine stars orbiting the massive black hole. Note that the orbits of the stars are not necessarily in the plane of the figure but rather have various orientations relative to observers on Earth.

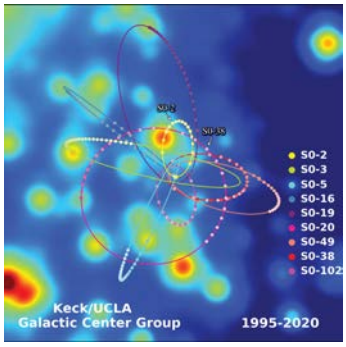

FIGURE 12.21 The orbits of nine stars close to the center of the Milky Way as tracked by astronomers from the Keck/UCLA Galactic Center Group from 1995 to 2020. The measured positions, represented by colored dots, are superimposed on a picture of the stars taken at the start of the tracking. The lines represent fits to the measurements of the stars' orbits. The size of the image is approximately $\frac{1}{15}$ of a light-year.

These images/animations were created by Prof. Andrea Ghez and her research team at UCLA and are from data sets obtained with the W. M. Keck Telescopes

One particular study (Boehl et al., 2016)* tracked the star S0-2 for more than a complete orbit and star S0-38 for almost a complete orbit. Astronomers extracted the parameters of the orbits of S0-2 and S0-38 by fitting the orientation of the plane of the orbits along with the

parameters of the orbits. The measurements of the semimajor axes are related to the distance of the massive black hole from Earth. The astronomers found that the massive black hole is 4.02 million times more massive than our Sun and is located 7.86 kpc ($2.43 \cdot 10^{20}$ m) from Earth. The periods of the orbits of S0-2 and S0-38 were found to be 15.9 and 19.2 years, respectively. Note that measured orbits can be described by Kepler's Third Law. What are the semimajor axes of the orbits of the stars S0-2 and S0-38?

SOLUTION

We can solve equation 12.31 to give the semimajor axis

$$a = \sqrt[3]{\frac{MGT^2}{4\pi^2}}.$$

The results for the semimajor axes for the orbits of S0-2 and S0-38 are given in Table 12.2.

Table 12.2 Semimajor Axes for Stars S0-2 and S0-38

Star	Period (yr)	Period $\left(10^8 \text{s}\right)$	Mass of Black Hole Solar Masses $\left(10^6\right)$	Mass of Black Hole $\left(10^{36}\text{kg}\right)$	Semimajo Axis $\left(10^{14}\text{ m}\right)$
S0-2	15.9	5.02	4.02	8.00	1.50
S0-38	19.2	6.06	4.02	8.00	7.71

DISCUSSION

If there is a supermassive black hole in the center of the Milky Way, you may ask yourself why isn't Earth being pulled toward it? The answer is the same as the answer to the question of why the Earth does not fall into the Sun: The Earth orbits the Sun, and the Sun orbits the galactic center, a distance of 26,000 light-years away from the Solar System.

An improved distance and mass estimate for SGR A from a multistar orbit analysis. *The Astrophysical Journal, 830*(1). doi:10.3847/0004-637x/830/1/17

Kepler's Second Law and Conservation of Angular Momentum

Chapter 10 (on rotation) stressed the importance of the concept of angular momentum, in particular, the importance of the conservation of angular momentum. It is quite straight-forward to prove the law of conservation of angular momentum for planetary motion and, as a consequence, also derive Kepler's Second Law. Let's work through this proof.

First, we show that the angular momentum, $\vec{L} = \vec{r} \times \vec{p}$, of a point particle is conserved if the particle moves under the influence of a central force. A **central force** is a force that acts only in the radial direction, $\vec{F}_{\text{central}} = F\hat{r}$. To prove this statement, we take the time derivative of the angular momentum:

$$\frac{d\vec{L}}{dt} = \frac{d}{dt}\left(\vec{r} \times \vec{p}\right) = \frac{d\vec{r}}{dt} \times \vec{p} + \vec{r} \times \frac{d\vec{p}}{dt}.$$

For a point particle, the velocity vector, $\vec{v} = d\vec{r}/dt$, and the momentum vector, $\vec{p}$ are parallel; therefore, their vector product vanishes: $\left(d\vec{r}/dt\right) \times \vec{p} = 0$. This leaves only the term $\vec{r} \times \left(d\vec{p}/dt\right)$ in the preceding equation. Using Newton's Second Law, we obtain (see Chapter 7 on momentum) $d\vec{p}/dt = \vec{F}$. If this force is a central force, then it is parallel (or antiparallel) to the vector $\vec{r}$. Thus, for a central force, the vector product $\vec{r} \times \left(d\vec{p}/dt\right)$ also vanishes:

$$\frac{d\vec{L}}{dt} = \vec{r} \times \frac{d\vec{p}}{dt} = \vec{r} \times \vec{F}_{\text{central}} = \vec{r} \times F\hat{r} = 0.$$

Since $d\vec{L}/dt = 0$, we have shown that angular momentum is conserved for a central force. The force of gravity is such a central force, and therefore angular momentum is conserved for any planet moving on an orbit.

How does this general result help in deriving Kepler's Second Law? If we can show that the area *dA* swept out by the radial vector, $\vec{r}$, during some infinitesimal time, *dt*, is proportional to the absolute value of the angular momentum, then we are done, because the angular momentum is conserved.

As you can see in Figure 12.22, the infinitesimal area dA swept out by the vector $\vec{r}$ is the triangle spanned by that vector and the differential change in it, $d\vec{r}$:

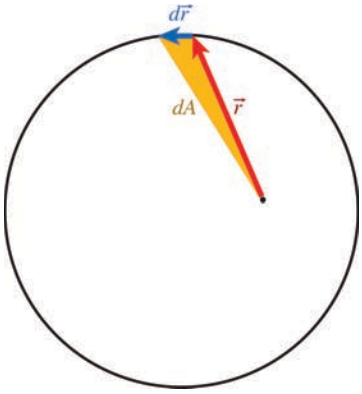

FIGURE 12.22 Area swept out by the radius vector.

$$dA = \tfrac{1}{2}\left|\vec{r}\times d\vec{r}\right| = \tfrac{1}{2}\left|\vec{r}\times \frac{d\vec{r}}{dt}dt\right| = \tfrac{1}{2}\left|\vec{r}\times \frac{1}{m}m\frac{d\vec{r}}{dt}dt\right| = \frac{dt}{2m}\left|\vec{r}\times\vec{p}\right| =$$

Therefore, the area swept out in each time interval, dt, is given by

$$\frac{dA}{dt} = \frac{|\vec{L}|}{2m} = \text{constant},$$

which is exactly what Kepler's Second Law states.

Concept Check 12.4

Which one of the following statements tells how to accurately measure the mass of the Moon?

a) Measure the distance from the Earth to the Moon, and then equate the force of gravity between the Earth and the Moon to the centripetal force required to keep the Moon in orbit around the Earth.

b) Measure the diameter of the Moon, calculate its volume, and then multiply by the density of water.

c) Measure the period of the Moon's orbit around the Earth and the distance from the Earth to the Moon, and then apply Kepler's Third Law.

d) Put a satellite in orbit around the Moon, measure the semimajor axis and the period of the satellite's orbit, and then apply Kepler's Third Law.

e) Measure the effect that the Moon has on the direction of Earth's rotational axis as the Moon orbits the Earth, and then apply the conservation of angular momentum.

12.6 Satellite Orbits

Figure 12.23 shows the positions of many of the several hundreds of satellites in orbit around Earth. Each dot represents the position of a satellite on the morning of December 13, 2021. The figure shows 61 low-orbit space stations including the Hubble Space Telescope and the International Space Station (red dots). The perfect circle of satellites at a distance of approximately 5.6 Earth radii above the surface (yellow dots) is composed of **geostationary satellites,** which orbit at the same angular speed as Earth, and so remain above the same spot on the ground. The satellites in between the geostationary and the low-orbit satellites (orange dots) are those used for the Global Positioning System. The plot shows an equatorial plane for reference. The arrows indicate motion out of this plane.

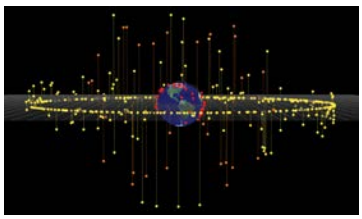

FIGURE 12.23
Positions of some of the satellites in orbit around Earth on December 13, 2021. This illustration was produced using the website in-the-sky.org, which uses Norad/Celestrak orbital elements.

SOLVED PROBLEM 12.3 Satellite in Orbit

PROBLEM

A satellite is in a circular orbit around the Earth. The orbit has a radius of 3.75 times the radius of the Earth. What is the linear speed of the satellite?

SOLUTION

THINK

The force of gravity provides the centripetal force that keeps the satellite in its circular orbit around the Earth. We can obtain the satellite's linear speed by equating the centripetal force expressed in terms of the linear speed with the force of gravity between the satellite and the Earth.

SKETCH

A sketch of the problem situation is presented in Figure 12.24.

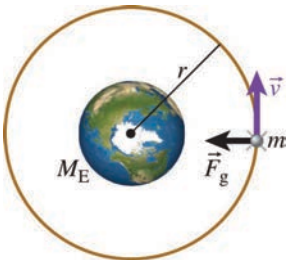

FIGURE 12.24
Satellite in circular orbit around the Earth.

RESEARCH

For a satellite with mass m moving with linear speed v, the centripetal force required to keep the satellite moving in a circle with radius r is

$$F_c = \frac{mv^2}{r}. \qquad \text{(i)}$$

The gravitational force, F_g, between the satellite and the Earth is

$$F_g = G\frac{M_E m}{r^2}, \qquad \text{(ii)}$$

where G is the universal gravitational constant and M_{E} is the mass of the Earth. Equating the forces described by equations (i) and (ii), we get

$$\begin{aligned} F_{\mathrm{c}} &= F_{\mathrm{g}} \Rightarrow \\ \frac{mv^2}{r} &= G\frac{M_{\mathrm{E}}m}{r^2}. \end{aligned}$$

SIMPLIFY

The mass of the satellite cancels out; thus, the orbital speed of a satellite does not depend on its mass. We obtain

$$\begin{aligned} v^2 &= G\frac{M_{\mathrm{E}}}{r} \Rightarrow \\ v &= \sqrt{\frac{GM_{\mathrm{E}}}{r}}. \end{aligned} \qquad \text{(iii)}$$

CALCULATE

The problem statement specified that the radius of the satellite's orbit is $r = 3.75R_{\mathrm{E}}$, where R_{E} is the radius of the Earth. Substituting for r in equation (iii) and then inserting the known numerical values gives us

$$v = \sqrt{\frac{GM_{\mathrm{E}}}{3.75R_{\mathrm{E}}}} = \sqrt{\frac{\left(6.67 \cdot 10^{-11}\ \mathrm{m^3 kg^{-1} s^{-2}}\right)\left(5.97 \cdot 10^{24}\ \mathrm{kg}\right)}{3.75\left(6.37 \cdot 10^{6}\ \mathrm{m}\right)}} = 4$$

ROUND

Expressing our result with three significant figures gives

$$v = 4080\ \mathrm{m/s} = 4.08\ \mathrm{km/s}.$$

DOUBLE-CHECK

The time it takes this satellite to complete one orbit is

$$T = \frac{2\pi r}{v} = \frac{2\pi(3.75R_{\mathrm{E}})}{v} = \frac{2\pi\left[3.75\left(6.37\cdot 10^{6}\ \mathrm{m}\right)\right]}{4080\ \mathrm{m/s}} = 36,800\ \mathrm{s} =$$

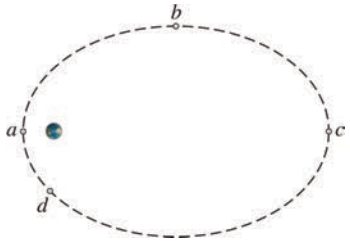
which seems reasonable—communication satellites take 24 h but are at higher altitudes, and the Hubble Space Telescope takes 1.6 h at a lower altitude.

Combining the expression for the orbital speed from Solved Problem 12.3, $v = \sqrt{GM_{\mathrm{E}}/r}$, with equation 12.15 for the escape speed, $v_{\mathrm{sec}} = \sqrt{2GM_{\mathrm{E}}/r}$, we find that the orbital velocity of a satellite is always

$$v(r) = \frac{1}{\sqrt{2}} v_{\mathrm{esc}}(r). \qquad \textbf{(12.22)}$$

Concept Check 12.5

The elliptical orbit of a small satellite orbiting a spherical planet is shown in the figure. At which point along the orbit is the linear speed of the satellite at a maximum?



The Earth is a satellite of the Sun, and, as we determined in Section 12.4, the escape speed from the Sun starting from the orbital radius of the Earth is 42 km/s. Using equation 12.22, we can predict that the orbital speed of the Earth moving around the Sun is $42/\sqrt{2}$ km/s, or approximately 30km/s, which matches the value of the orbital speed we found in Chapter 9.

Energy of a Satellite

Having worked through Solved Problem 12.3, we can readily obtain an expression for the kinetic energy of a satellite in orbit around Earth. Multiplying both sides of $mv^2/r = GM_{\mathrm{E}}\, m/r^2$, which we found by equating the centripetal and gravitational forces, by $r/2$ yields

$$\tfrac{1}{2}mv^2 = \tfrac{1}{2}G\frac{M_{\mathrm{E}}m}{r}.$$

The left-hand side of this equation is the kinetic energy of the satellite. Comparing the right-hand side to the expression for the gravitational potential energy, $U = -GM_{\mathrm{E}}m/r$, we see that this side is equivalent to $-\tfrac{1}{2}U$. Thus, we obtain the kinetic energy of a satellite in circular orbit:

$$K = -\tfrac{1}{2}U. \qquad \textbf{(12.23)}$$

Concept Check 12.6

The International Space Station orbits Earth once every 90 min. Which letter in the figure below is closest to its orbit?

NASA

Concept Check 12.7

Which letter in the figure is closest to the orbit of a geostationary satellite?

The total mechanical energy of the satellite is then

$$E = K + U = -\tfrac{1}{2}U + U = \tfrac{1}{2}U = -\tfrac{1}{2}G\frac{M_{\mathrm{E}}m}{r}. \qquad \textbf{(12.24)}$$

Consequently, the total energy is exactly the negative of the satellite's kinetic energy:

$$E = -K. \qquad \textbf{(12.25)}$$

It is important to note that equations 12.23 through 12.25 all hold for any orbital radius.

For an elliptical orbit with a semimajor axis a, obtaining the energy of the satellite requires a little more mathematics. The result is very similar to equation 12.24, with the radius r of the circular orbit replaced by the semimajor axis a of the elliptical orbit:

$$E = -\tfrac{1}{2} G \frac{M_{\mathrm{E}} m}{a}.$$

Orbit of Geostationary Satellites

For many applications, a satellite needs to remain at the same point in the sky. For example, a satellite TV dish always points to the same place in the sky, and a satellite has to be located there to ensure that the dish can receive a signal. Satellites that are continuously at the same point in the sky are said to be *geostationary*.

What are the conditions that a satellite must fulfill to be geostationary? First, it has to move in a circle, because this is the only orbit that has a constant angular velocity. Second, the period of rotation must match that of the Earth's, exactly 1 day. And third, the axis of rotation of the satellite's orbit must be exactly aligned with that of the Earth's rotation. Because the center of the Earth must be at the center of a circular orbit for any satellite, the only possible geostationary orbit is one exactly above the Equator. These conditions leave only the radius of the orbit to be determined.

To find the radius, we use Kepler's Third Law in the form of equation 12.19 and solve for r:

$$\frac{T^2}{r^3} = \frac{4\pi^2}{GM} \Rightarrow r = \left(\frac{GMT^2}{4\pi^2}\right)^{1/3}. \qquad \textbf{(12.26)}$$

The mass M in this case is that of the Earth. Inserting the numerical values, we find

$$r = \left(\frac{\left(6.674 \cdot 10^{-11}\,\mathrm{m^3 kg^{-1} s^{-2}}\right)\left(5.9736 \cdot 10^{24}\,\mathrm{kg}\right)\left(86,164\,\mathrm{s}\right)^2}{4\pi^2}\right)^{1/3} =$$

Note that we used the best available value of the mass of the Earth and the sidereal day as the correct period of the Earth's rotation (see Chapter 9). The distance of a geostationary satellite above sea level at the Equator is then $42,167\,\mathrm{km} - R_\mathrm{E}$. Taking into account that the Earth is not a perfect sphere, but slightly oblate, this distance is

$$d = r - R_\mathrm{E} = 35{,}790\,\mathrm{km}.$$

This distance is 5.61 times Earth's radius. This is why the geostationary satellites form an almost perfect circle with a radius of $6.61 R_\mathrm{E}$ in Figure

12.23.

Figure 12.25 shows a cross section through Earth and the location of a geostationary satellite, with the radius of its orbit drawn to scale. This figure shows the angle ξ relative to the horizontal at which to orient a satellite dish for the best TV reception. Because any geostationary satellite is located in the plane of the Equator, a dish in the Northern Hemisphere should point in a southerly direction.

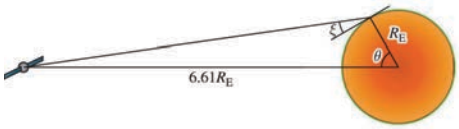


FIGURE 12.25 Angle of a satellite dish, ξ, relative to the local horizontal as a function of the angle of latitude, θ.

There are also geosynchronous satellites in orbit around the Earth. A geosynchronous satellite also has an orbital period of 1 day but does not need to remain at the same point in the sky as viewed from the surface of Earth. For example, NASA's Solar Dynamics Observatory (which was launched in February 2010) has a geosynchronous orbit that is inclined and that traces out a figure 8 in the sky as viewed from the ground. A geostationary orbit is a special case of a geosynchronous orbit.

SOLVED PROBLEM 12.4 Satellite TV Dish

You just received your new television system, but the company cannot come out to install the dish for you immediately. You want to watch the big game tonight, so you decide to set up the satellite dish yourself.

PROBLEM

Assuming that you live in a location at latitude 42.75° N and that the satellite TV company has a satellite aligned with your longitude, in what direction should you point the satellite dish?

SOLUTION

THINK

Satellite TV companies use geostationary satellites to broadcast the signals. Thus, we know you need to point the satellite dish southward, toward the Equator, but you also need to know the angle of inclination of the satellite dish with respect to the horizontal. In Figure 12.25, this is the angle ξ. To determine ξ, we can use the law of cosines, incorporating the distance of a satellite in geostationary orbit, the radius of the Earth, and the latitude of the location of the dish.

SKETCH

Figure 12.26 is a sketch of the geometry of the location of the geostationary satellite and the point on the surface of the Earth where the dish is being set up. In this sketch, R_E is the radius of the Earth, R_S is the distance of the satellite from the center of the Earth, d_S is the distance from the satellite to the point on the Earth's surface where the dish is located, θ is the angle of the latitude of the surface of that location, and ϕ is the angle between d_S and R_E.

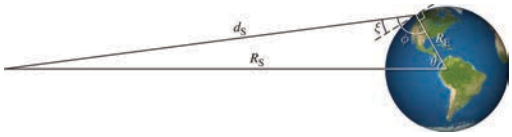

FIGURE 12.26 Geometry of a geostationary satellite in orbit around the Earth.

RESEARCH

To determine the angle ξ, we first need to determine the angle $\boldsymbol{\phi}$. We can see from Figure 12.26 that $\xi = \phi - 90^\circ$ because the dashed line is tangent to the surface of the Earth and thus is perpendicular to a line from the point to the center of the Earth. To determine $\boldsymbol{\phi}$, we can apply the law of cosines to the triangle defined by d_S, R_E, and R_S. We will need to apply the law of cosines to this triangle twice. To use the law of cosines to determine $\boldsymbol{\phi}$, we need to know the lengths of the sides d_S and R_E. We know R_E but not d_S. We can determine the length d_S using the law of cosines, the angle θ, and the lengths of the two known sides of R_E and R_S:

$$d_\text{S}^2 = R_\text{S}^2 + R_\text{E}^2 - 2R_\text{S}R_\text{E}\cos\theta. \qquad \text{(i)}$$

We can now get an equation for the angle $\boldsymbol{\phi}$ using the law of cosines with the angle $\boldsymbol{\phi}$ and the two known lengths d_S and R_E:

$$R_\text{S}^2 = d_\text{S}^2 + R_\text{E}^2 - 2d_\text{S}R_\text{E}\cos\phi. \qquad \text{(ii)}$$

SIMPLIFY

We know that $R_\text{S} = 6.61R_\text{E}$ for geostationary satellites. The angle θ corresponds to the latitude, $\theta = 42.75^\circ$. We can substitute these quantities into equation (i):

$$d_\text{S}^2 = (6.61R_\text{E})^2 + R_\text{E}^2 - 2(6.61R_\text{E})R_\text{E}(\cos 42.75^\circ).$$

We can now write an expression for d_S in terms of R_E:

$$d_\text{S}^2 = R_\text{E}^2\left[6.61^2 + 1 - 2(6.61)(\cos 42.75^\circ)\right] = 34.984\,R_\text{E}^2,$$

or

$$d_\text{S} = 5.915R_\text{E}.$$

We can solve equation (ii) for $\boldsymbol{\phi}$:

$$\phi = \cos^{-1}\left(\frac{d_\text{S}^2 + R_\text{E}^2 - R_\text{S}^2}{2d_\text{S}R_\text{E}}\right). \qquad \text{(iii)}$$

CALCULATE

Inserting the values we have for d_S and R_S into equation (iii) gives

$$\phi = \cos^{-1}\left(\frac{34.984R_E^2 + R_E^2 - (6.61R_E)^2}{2(5.195R_E)R_E}\right) = 130.66^\circ.$$

The angle at which you need to aim the satellite dish with respect to the horizontal is then

$$\xi = \phi - 90^\circ = 130.66^\circ - 90^\circ = 40.66^\circ.$$

ROUND

Expressing our result with three significant figures gives

$$\xi = 40.7^\circ.$$

DOUBLE-CHECK

If the satellite were very far away, the lines d_S and R_S would be parallel to each other, and the sketch of the geometry of the situation would be redrawn as shown in Figure 12.27. We can see from this sketch that $\phi = 180^\circ - \theta$. Remembering that $\xi = \phi - 90^\circ$, we can write

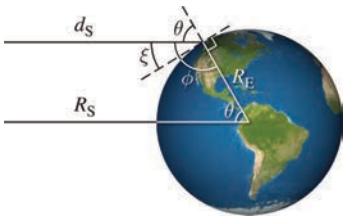

FIGURE 12.27 Geometry for a satellite that is very far away.

$$\xi = (180^\circ - \theta) - 90^\circ = 90^\circ - \theta.$$

In this situation, $\theta = 42.75^\circ$, so the estimated angle would be $\xi = 90^\circ - 42.75^\circ = 47.25^\circ$, which is close to our result of $\xi = 40.7^\circ$, but definitely larger, as required. Thus, our answer seems reasonable.

Concept Check 12.8

If a permanent base is established on Mars, it will be necessary to have Martian-stationary satellites in orbit around Mars to facilitate communications. A day on Mars lasts 24 h, 37 min, and 22 s. What is the radius of the orbit for a Martian-stationary satellite?

a) 12,560 km

b) 15,230 km

c) 20,430 km

d) 29,320 km

e) 43,350 km

12.7 Dark Matter

In the Solar System, almost all of the matter is concentrated in the Sun. The mass of the Sun is approximately 750 times greater than the mass of all planets combined (refer to Table 12.1). The Milky Way, our home galaxy, contains giant clouds of gas and dust, but their combined mass is only about a tenth of that contained in the galaxy's stars. Extrapolating from these facts, you might conclude that the entire universe is composed almost exclusively of luminous matter—that is, stars. Nonluminous matter in the form of dust, asteroids, moons, and planets should contribute only a small fraction of the mass of the universe.

Astronomers know the typical masses of stars and can estimate their numbers in galaxies. Thus, they have obtained fairly accurate estimates of the masses of galaxies and clusters of galaxies. Furthermore, they use modern X-ray telescopes, such as Chandra, to take images of the hot interstellar gas trapped within galaxy clusters. They can deduce the temperature of this gas from the X-ray emissions, and they can also determine how much gravitational force it takes to keep this hot gas from escaping the galaxy clusters. The surprise that has emerged from this research is that the mass contained in luminous matter is too small by a factor of approximately 3 to 5 to provide this gravitational force. This analysis leads to the conclusion that there must be other matter, referred to as *dark matter,* which provides the missing gravitational force.

Some of the observational evidence for dark matter has emerged from measurements of the orbital speeds of stars around the center of their galaxy as a function of their distance from the center, as shown in Figure 12.28 for M 31, the Andromeda galaxy. Even if we assume that there is a supermassive black hole, which is obviously nonluminous, at the center of the galaxy, we would expect star velocity to fall off toward zero for large distances from the center. Experimental evidence, however, indicates that this is not the case. Thus, it is likely that large quantities of dark matter, with a very large radial extent, are present.

EXAMPLE 12.5 Expectations for the Observed Linear Speed of Objects Orbiting Andromeda

PROBLEM

Figure 12.28 shows the measurement of the linear speed of objects orbiting around the center of the Andromeda galaxy. What would we expect for the linear speed as a function of the observing angle if the objects were outside the galaxy and there were no dark matter?

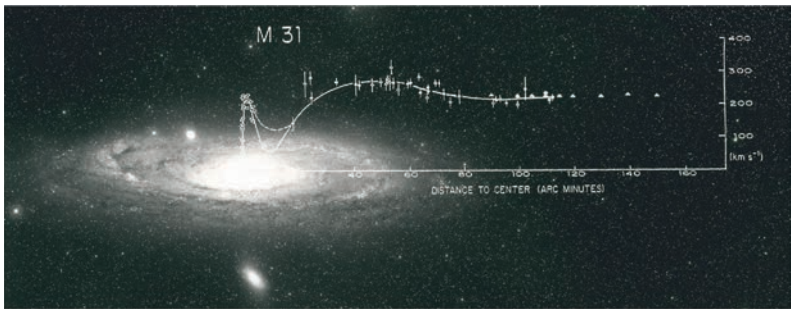

FIGURE 12.28 Image of the Andromeda galaxy, with data on the orbital speeds of stars superimposed. (The triangles represent radio-telescope data from 1975, and the other symbols show optical-wavelength observations from 1970; the solid and dashed lines are simple fits to guide the eye.) The main feature of interest here is that the orbital speeds remain approximately constant well outside the luminous portion of Andromeda, indicating the presence of dark matter.

Carnegie Institution for Science/Vera C. Rubin and Janice S. Dunlap

Page 384

SOLUTION

In the absence of dark matter, the gravitational force of the mass of the galaxy acting on objects outside the galaxy provides the centripetal force to keep the objects in orbit around the galaxy. Assuming circular orbits, the centripetal force required to keep an object with mass m moving with linear speed v in orbit a distance r from the center of the galaxy is given by mv^2/r. The gravitational force of the galaxy with mass M acting in this object is GmM/r^2. Equating these two and solving for the linear speed gives us

$$\frac{mv^2}{r} = G\frac{mM}{r^2} \rightarrow v = \sqrt{\frac{GM}{r}}. \qquad \text{(i)}$$

Note that the mass of the object cancels out. The observation angle θ is related to distance to the galaxy d as $d = r\theta$, assuming θ is small and d is large. Figure 12.29 shows the geometry of these observations.

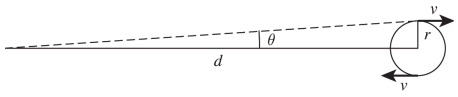

FIGURE 12.29 Geometry for observing the linear speed of objects orbiting the Andromeda galaxy.

The observed linear speed is related to the observation angle by

$$v = \sqrt{\frac{GM}{r}} = \sqrt{\frac{GM}{\theta d}}. \qquad \text{(ii)}$$

Looking at Figure 12.28, it seems that most of the luminous mass of Andromeda is inside $\theta = 60$ arc minute. An arc minute corresponds to an angle of 0.000291 radians. We take the mass of Andromeda to be $1.85 \cdot 10^{11}$ solar masses $\left(3.68 \cdot 10^{41}\ \text{kg}\right)$ from Rubin and Ford's paper* and the measured distance to Andromeda to be $2.54 \cdot 106$ light-years $\left(2.40 \cdot 10^{22}\ \text{m}\right)$. Figure 12.30 shows what we expect for v as a function of θ if all the mass of Andromeda were inside $\theta = 60$ arc minutes.

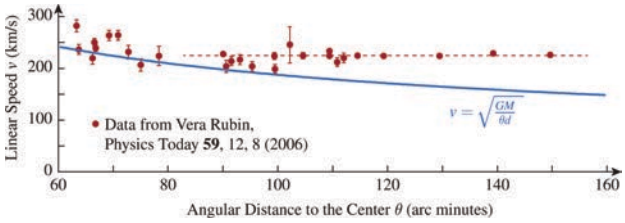

FIGURE 12.30 Plot of the observed linear speed for objects in the Andromeda galaxy as a function of the observed angular distance from the center of the galaxy. The solid line represents a calculation assuming most of the mass of the galaxy is inside 60 arc minutes. The dashed line shows a constant linear speed with angular distance.

DISCUSSION

The observed linear speeds do not decrease with observation angle as expected for objects orbiting the center of Andromeda outside the luminous regions of the galaxy. Instead, the speeds are nearly constant with the angular distance from $\theta = 80$ to 150 arc minutes. This result implies that there must be unobserved mass that keeps the linear speeds from decreasing with observation angle. Astronomers now think there must be unseen mass in the form of dark matter that provides the missing force.

Other evidence for dark matter has emerged from observations of gravitational lensing. In Figure 12.31a, the light blue shading represents the distribution of dark matter around a galaxy cluster, as calculated from the observed gravitational lensing. In Figure 12.31b, white circles mark the positions of five images of the same galaxy produced by the gravitational lensing from the unseen dark matter. (Gravitational lensing will be explained in Chapter 35 on relativity. For now, this observation is presented simply as one more empirical fact pointing toward the existence of dark matter.)

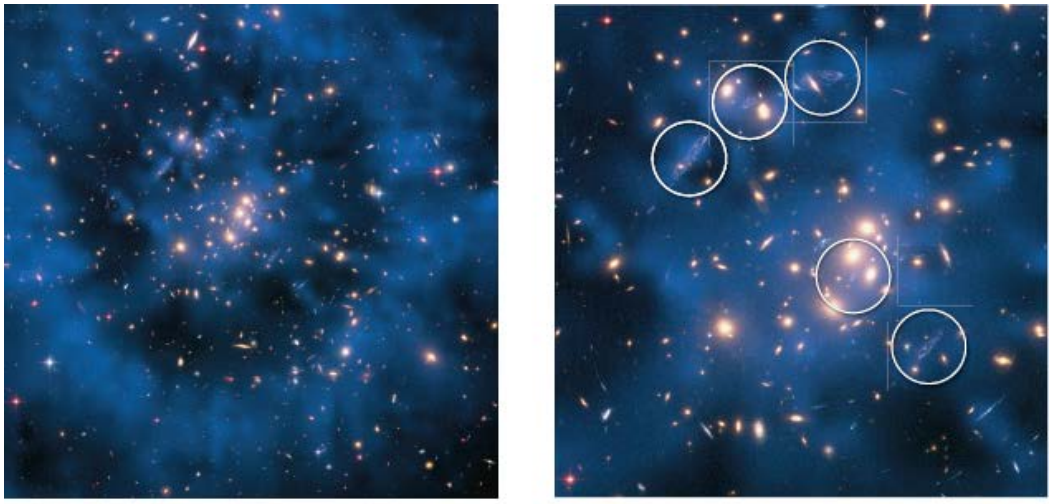

FIGURE 12.31 An example of gravitational lensing by dark matter. (a) Photograph of the galaxy cluster Cl 0024 + 17 taken with the Hubble Space Telescope. The light blue shading represents the distribution of dark matter based on the observed gravitational lensing. (b) Expanded section of the center section of the photograph in part (a), with five images of the same galaxy produced by gravitational lensing marked by circles.

a-b: NASA, ESA, M.J. Jee and H. Ford (Johns Hopkins University)

Supporting data have also emerged from the WMAP (Wilkinson Microwave Anisotropy Probe) mission, which measured the cosmic background radiation left over from the Big Bang. The best estimate based on this data is that 23% of the universe is composed of dark matter. In addition, the combination of images from the Hubble Space Telescope, the Chandra X-ray Observatory, and the Magellan telescope has yielded a direct empirical proof of the existence of dark matter in the "bullet cluster" (Figure 12.32). The measured temperature of the intergalactic gas in this galaxy cluster is too large for the gas to be contained within the cluster without the presence of dark matter.

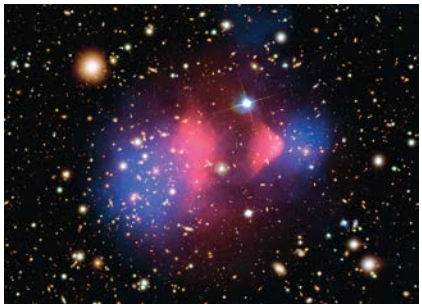

FIGURE 12.32
Superposition of X-ray and optical images of the "bullet cluster," galaxy cluster 1E 0657-56, which contains direct empirical proof of the existence of dark matter.

Chandra X-ray Observatory/NASA

Intense speculation and extensive theoretical investigation as to the nature of this dark matter have been ongoing during the last few years, and theories about it are still being modified as new observations emerge. However, all of the proposed theories require a fundamental rethinking of the standard model of the universe and quite possibly of the fundamental models for the interaction of particles. Whimsical names have been suggested for the possible constituents of dark matter, such as WIMP (Weakly Interacting Massive Particle) or MACHO (Massive Astrophysical Compact Halo Object). (The physical properties of these postulated constituents are being actively investigated.)

During the last few years, an even stranger phenomenon has been discovered: It seems that, in addition to dark matter, there is also *dark energy*. This dark energy seems to be responsible for an increasing acceleration in the expansion of the universe. A stunning 73% of the mass-energy of the universe is estimated to be dark energy. Together with the 23% estimated to be dark matter, this leaves only 4% of the universe for the stars, planets, moons, gas, and all other objects made of conventional matter.

These are very exciting new areas of research that are sure to change our picture of the universe in the coming decades.

EXAMPLE 12.6 Distance of the James Webb Space Telescope from Earth

PROBLEM

Lagrange points are positions in space where objects tend to stay put. The James Webb Space Telescope (JWST) is deployed at the L2 Lagrange point to allow it to be permanently oriented away from the heat signatures of the Sun and Earth while remaining near Earth. The L2 Lagrange point corresponds to the point where the gravitation forces from the Sun and Earth acting on the JWST provide the centripetal force to keep the JWST orbiting in a circle around the Sun with the same angular velocity as the Earth. What is the distance of the JWST from the Earth?

Page 386

SOLUTION

We take the distance from the Earth to the Sun to be R and the distance from Earth to the L2 point to be d_{L2} as shown in Figure 12.33.

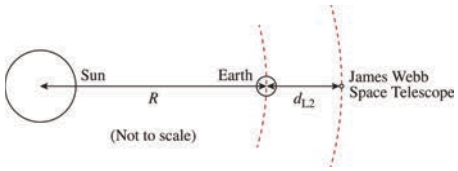

FIGURE 12.33 Sketch showing the relative positions of the Sun, the Earth, and the JWST orbiting at the L2 Lagrange point (not to scale).

We make the simplifying assumptions that the Sun remains stationary and that the Earth and the JWST execute circular orbits around the Sun. For the JWST to stay at L2, the Earth and the JWST must orbit the Sun with the same angular velocity, ω. We get an expression for ω^2 by equating the centripetal force required to keep the Earth orbiting in a circle around the Sun with the gravitation force between the Earth and the Sun:

$$m_{\text{Earth}} R\omega^2 = G\frac{m_{\text{Earth}} m_{\text{Sun}}}{R^2}$$

$$\omega^2 = \frac{Gm_{\text{Sun}}}{R^3}.$$

We equate the centripetal force required to keep the JWST in a circular orbit around the Sun with the forces of gravity of the Sun and Earth acting on the JWST with mass m:

$$m(R+d_{\mathrm{L2}})\omega^2 = G\frac{mm_{\mathrm{Sun}}}{(R+d_{\mathrm{L2}})^2} + G\frac{mm_{\mathrm{Earth}}}{(d_{\mathrm{L2}})^2}.$$

Inserting our expression for ω^2 and cancelling m and G we get

$$(R+d_{\mathrm{L2}})\frac{m_{\mathrm{Sun}}}{R^3} = \frac{m_{\mathrm{Sun}}}{(R+d_{\mathrm{L2}})^2} + \frac{m_{\mathrm{Earth}}}{(d_{\mathrm{L2}})^2}.$$

We introduce the mass ratio of the Sun and Earth, $M = m_{\mathrm{Sun}}/m_{\mathrm{Earth}}$. Multiplying the previous equation with m_{Earth} and with $(d_{\mathrm{L2}})^2(R+d_{\mathrm{L2}})/R^2$ then results in

$$(d_{\mathrm{L2}}/R)^2(1+d_{\mathrm{L2}}/R)^3M = M((d_{\mathrm{L2}}/R)^2(1+d_{\mathrm{L2}}/R)^2.$$

To simplify the appearance of our equation, we introduce another dimensionless ratio $\varrho = d_{\mathrm{L2}}/R$, i.e. the distance from Earth to L2 in units of the distance from Earth to the Sun. This allows us to write the above as

$$\begin{aligned}
\varrho^2(1+\varrho)^3M &= M\varrho^2 + (1+\varrho)^2 \\
M\varrho^2 + 3M\varrho^3 + 3M\varrho^4 + M\varrho^5 &= M\varrho^2 + 1 + 2\varrho + \varrho^2 \\
3M\left(\varrho^3 + \varrho^4 + \varrho^5/3\right) &= 1 + 2\varrho + \varrho^2
\end{aligned}$$

In the second line we multiplied out all products, and in the third line we subtracted $M\varrho^2$ on both sides. Since M = 333,000 for the Sun/Earth mass ratio, it is clear that $\varrho \ll 1$. We can then approximate by neglecting the second and third term on both sides of this equation and find $3M\varrho^3 \approx 1$, which means

$$\varrho \approx \sqrt[3]{\frac{1}{3M}} \approx 10^{-2} \quad \text{and therefore } d_{\mathrm{L2}} \approx 10^{-2}R = 1.5 \text{ million km}$$

DISCUSSION

Our approximation is very close to the exact answer of 1.502 million km, which is obtained by also including the fact that Earth and Sun are rotating around the common center of mass, as well as the eccentricity of

Earth orbit. The distance of the JWST from Earth is 3.9 times the distance of the Earth to the Moon. Figure 12.34 shows the five Lagrange points for the Sun and Earth. L1, L2, and L3 are all located on the Sun-Earth axis, and L4 and L5 form equilateral triangles with the Earth and the Sun. L1 is approximately the same distance from Earth as L2, but on the side that always faces the sun. The Lagrange points L1, L2, and L3 are unstable equilibrium points while L4 and L5 are stable equilibrium points.

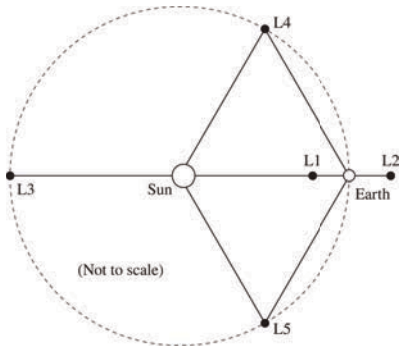

FIGURE 12.34 The five Lagrange points for the Sun and Earth.

Concept Check 12.9

With the JWST located at L2, the Earth always is exactly between the telescope and the Sun. The Sun has a radius of 695,700 km and the Earth has a radius of 6,370 km. Can you see the Sun from the location of the JWST?

a) Yes, always. The Earth is just a minor speck compared to the Sun.

b) Yes, but only as a very thin annular ring.

c) No, the Sun is completely obscured.

Self-Test Opportunity 12.4

The Earth-Moon system also has 5 Lagrange points. Calculate how far the L2 Lagrange point for the Earth and Moon system is from the center of the Moon. This location could be used for staging interplanetary space travel. Take $m_{\text{Earth}} = 5.972 \cdot 10^{24}$ kg, $m_{\text{Moon}} = 7.342 \cdot 10^{22}$ kg, and the distance between the Earth and Moon to be $R = 3.844 \cdot 10^{8}$ m. Assume the Earth remains stationary, and the Moon executes a circular orbit around the Earth.

WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- The gravitational force between two point masses is proportional to the product of their masses and inversely proportional to the distance between them, $F(r) = G\frac{m_1 m_2}{r^2}$, with the proportionality constant $G = 6.674 \cdot 10^{-11}\ \mathrm{m^3 kg^{-1} s^{-2}}$, known as the universal gravitational constant.
- In vector form, the equation for the gravitational force can be written as $\vec{F}_{2\to 1} = G\frac{m_1 m_2}{\left|\vec{r}_2 - \vec{r}_1\right|^3}\left(\vec{r}_2 - \vec{r}_1\right)$. This is Newton's Law of Gravity.
- If more than two objects interact gravitationally, the resulting force on one object is given by the vector sum of the forces acting on it due to the other objects.
- Near the surface of the Earth, the gravitational acceleration can be approximated by the function $g(h) = g\left(1 - 2\frac{h}{R_\mathrm{E}} + \cdots\right)$; that is, it falls off linearly with height above the surface.
- The gravitational acceleration at sea level can be derived from Newton's Law of Gravity: $g = \frac{GM_\mathrm{E}}{R_\mathrm{E}^2}$.
- No gravitational force acts on an object inside a massive spherical shell. Because of this, the gravitational force inside a uniform sphere increases linearly with radius: $F(r) = \frac{4}{3}\pi G\rho m r$.
- The gravitational potential energy between two objects is given by $U(r) = -G\frac{m_1 m_2}{r}$.
- The escape speed from the surface of the Earth is $v_\mathrm{E} = \sqrt{\frac{2GM_\mathrm{E}}{R_\mathrm{E}}}$.
- Kepler's laws of planetary motion are as follows
  - All planets move in elliptical orbits with the Sun at one focal point.
  - A straight line connecting the center of the Sun and the center of any planet sweeps out an equal area in any given time interval: $\frac{dA}{dt} = \text{constant}$.

- The square of the period of a planet's orbit is proportional to the cube of the semimajor axis of the orbit: $\frac{T^2}{a^3} = \text{constant}$.

- The relationships of the kinetic, potential, and total energy of a satellite in a circular orbit are
  $K = -\frac{1}{2}U$, $E = K + U = -\frac{1}{2}U + U = \frac{1}{2}U = -\frac{1}{2}G\frac{Mm}{r}$, $E = -K$.
- Geostationary satellites have an orbit that is circular, above the Equator, and with a radius of 42,168 km.
- Evidence points strongly to the existence of dark matter and dark energy, which make up the vast majority of the universe.

ANSWERS TO SELF-TEST OPPORTUNITIES

12.1 The derivation is almost identical, but the integration from $R-r$ to $R+r$ yields zero force. Another proof, based on geometry, is given in Derivation 12.2.

12.2 $g_{\mathrm{d}} = g/9 = 1.09\,\mathrm{m/s^2}$.

12.3 Gravitational attraction between Sun and Earth provides the centripetal force to keep Earth in orbit around the Sun.

$$\frac{m_{\mathrm{E}}v^2}{r} = G\frac{m_{\mathrm{E}}M}{r^2}$$

The mass of Earth cancels. Next, substitute for v from $v = \dfrac{2\pi r}{T}$; then solve for M:

$$\frac{\left(\dfrac{2\pi r}{T}\right)^2}{r} = G\frac{M}{r^2} \Rightarrow M = \frac{(2\pi)^2 r^3}{GT^2}.$$

12.4 In this case the mass ratio M introduced in Example 12.6 is $M = 5.972 \cdot 10^{24}\ \mathrm{kg}\,/7.342 \cdot 10^{22}\ \mathrm{kg} = 81.34$.

Therefore $\varrho \approx \sqrt[3]{\dfrac{1}{3M}} \approx 0.16$ and we find for $d_{\mathrm{L2}} \approx 10^{-2}R = 62000\ \mathrm{km}$.
(This simple approximation is close to the exact value of $\varrho = 0.1678$, obtained by also including the higher order corrections and the motion of the Earth-Moon system around the system's center of mass.)

PROBLEM-SOLVING GUIDELINES: GRAVITATION

1. This chapter introduced the general form of the equation for the gravitational force, so the approximation $F = mg$ is no longer valid in general. Be sure to keep in mind that in general the acceleration due to gravity is not constant. And this means that you are not able to use the kinematic equations of Chapters 2 and 3 to solve gravitation problems.

2. Energy conservation is essential for many dynamic problems involving gravitation. Be sure to remember that the gravitational potential energy is not given simply by $U = mgh$, as presented in Chapter 6.

3. The principle of superposition of forces is important for situations involving interactions of more than two objects. It allows you to calculate the forces between the objects pairwise and then add them appropriately.

4. For planetary and satellite orbits, Kepler's laws are very useful computational tools, enabling you to connect orbital periods and orbital radii.

MULTIPLE-CHOICE QUESTIONS

12.1 A planet is in a circular orbit about a remote star, far from any other object in the universe. Which of the following statements is true?

a) There is only one force acting on the planet.

b) There are two forces acting on the planet and their resultant is zero.

c) There are two forces acting on the planet and their resultant is not zero.

d) None of the above statements are true.

12.2 Two 30.0-kg masses are held at opposite corners of a square of sides 20.0 cm. If one of the masses is released and allowed to fall toward the other mass, what is the acceleration of the first mass just as it is released? Assume that the only force acting on the mass is the gravitational force of the other mass.

a) $1.52 \cdot 10^{-7}\ \mathrm{m/s^2}$

b) $2.50 \cdot 10^{-7}\ \mathrm{m/s^2}$

c) $7.50 \cdot 10^{-7}\ \mathrm{m/s^2}$

d) $3.73 \cdot 10^{-7}\ \mathrm{m/s^2}$

12.3 With the usual assumption that the gravitational potential energy goes to zero at infinite distance, the gravitational potential energy due to the Earth at its center is

a) positive.

b) negative.

c) zero.

d) undetermined.

12.4 A man inside a sturdy box is fired out of a cannon. Which of the following statements regarding the man's sensation of weightlessness is correct?

a) The man senses weightlessness only when he and the box are traveling upward.

b) The man senses weightlessness only when he and the box are traveling downward.

c) The man senses weightlessness when he and the box are traveling both upward and downward.

d) The man does not sense weightlessness at any time of the flight.

12.5 In a binary star system consisting of two stars of equal mass, where is the gravitational potential equal to zero?

a) exactly halfway between the stars

b) along a line bisecting the line connecting the stars

c) infinitely far from the stars

d) none of the above

12.6 Two planets have the same mass, *M*, but one of them is much denser than the other. Identical objects of mass *m* are placed on the surfaces of the planets. Which object will have the gravitational potential energy of larger magnitude?

a) Both objects will have the same gravitational potential energy.

b) The object on the surface of the denser planet will have the larger gravitational potential energy.

c) The object on the surface of the less dense planet will have the larger gravitational potential energy.

d) It is impossible to tell.

12.7 Two planets have the same mass, *M*. Each planet has a constant density, but the density of planet 2 is twice as high as that of planet 1. Identical objects of mass *m* are placed on the surfaces of the planets. What is the relationship of the gravitational potential energy on planet 1 (U_1) to that on planet 2 (U_2)?

a) $U_1 = U_2$

b) $U_1 = \frac{1}{2}U_2$

c) $U_1 = 2U_2$

d) $U_1 = 1.26U_2$

e) $U_1 = 0.794U_2$

12.8 For two identical satellites in circular motion around the Earth, which statement is true?

a) The one in the lower orbit has less total energy.

b) The one in the higher orbit has more kinetic energy.

c) The one in the lower orbit has more total energy.

d) Both have the same total energy.

12.9 Which condition do all geostationary satellites orbiting the Earth have to fulfill?

a) They have to orbit above the Equator.

b) They have to orbit above the poles.

c) They have to have an orbital radius that locates them less than 30,000 km above the surface.

d) They have to have an orbital radius that locates them more than 42,000 km above the surface.

12.10 An object is placed between the Earth and the Moon, along the straight line that joins their centers. About how far away from the center of the Earth should the object be placed so that the net gravitational force on the object from the Earth and the Moon is zero?

a) halfway to the center of the Moon

b) 60% of the way to the center of the Moon

c) 70% of the way to the center of the Moon

d) 85% of the way to the center of the Moon

e) 90% of the way to the center of the Moon

12.11 A man of mass 100. kg feels a gravitational force, F_{m}, from a woman of mass 50.0 kg sitting 1 m away. The gravitational force, F_{w}, experienced by the woman will be _____ that experienced by the man.

a) more than

b) less than

c) the same as

d) not enough information given

12.12 Halfway between Earth's center and its surface, the gravitational acceleration is

a) zero.

b) $g/4$.

c) $g/2$.

d) $2g$.

e) $4g$.

12.13 The best estimate of the orbital period of the Solar System around the center of the Milky Way is between 220 and 250 million years. How much mass (in terms of solar masses) is enclosed by the 26,000 light-years $\left(1.7 \cdot 10^9 \text{ AU}\right)$ radius of the Solar System's orbit? (An orbital period of 1 yr for an orbit of radius 1 AU corresponds to 1 solar mass.)

a) 90 billion solar masses

b) 7.2 billion solar masses

c) 52 million solar masses

d) 3.7 million solar masses

e) 432,000 solar masses

12.14 Imagine a large hollow sphere with mass *M* and outer radius *R* located in outer space. The hollow sphere has a thickness *t*, where $t \ll R$. What is the gravitational force on an object with mass *m* on the outer and inner surfaces of the hollow sphere, respectively?

a) zero, zero

b) mMG/R^2, zero

c) zero, $mMG/(R-t)^2$

d) $mMG/R^2, mMG/(R-t)^2$

e) zero, mMG/R^2

12.15 The ratio of the mass of the Earth to the mass of the Moon is 81. The magnitude of the gravitational force that the Earth exerts on the Moon is

a) the same as the magnitude of the gravitational force that the Moon exerts on the Earth.

b) 81 times the gravitational force exerted by the Moon on the Earth.

c) 1/81 of the gravitational force exerted by the Moon on the Earth.

d) 9 times the gravitational force exerted by the Moon on the Earth.

e) 1/9 of the gravitational force exerted by the Moon on the Earth.

CONCEPTUAL QUESTIONS

12.16 Can the expression for gravitational potential energy $U_g(y) = mgy$ be used to analyze high-altitude motion? Why or why not?

12.17 Even though the Moon does not have an atmosphere, the trajectory of a projectile near its surface is only approximately a parabola. This is because the acceleration due to gravity near the surface of the Moon is only approximately constant. Describe as precisely as you can the *actual* shape of a projectile's path on the Moon, even one that travels a long distance over the surface of the Moon.

12.18 A scientist working for a space agency has noticed that a Russian satellite of mass 250. kg is on collision course with an American satellite of mass 600. kg orbiting at 1000. km above the surface. Both satellites are moving in circular orbits but in opposite directions. If the two satellites collide and stick together, will they continue to orbit or crash to the Earth? Explain.

12.19 Three asteroids, located at points P_1, P_2, and P_3, which are not in a line, and having known masses m_1, m_2, and m_3, interact with one another through their mutual gravitational forces only; they are isolated in space and do not interact with any other bodies. Let σ denote the axis going through the center of mass of the three asteroids, perpendicular to the triangle $P_1P_2P_3$. What conditions should the angular velocity ω of the system (around the axis σ) and the distances

$$P_1P_2 = a_{12}, \quad P_2P_3 = a_{23}, \quad P_1P_3 = a_{13},$$

fulfill to allow the shape and size of the triangle $P_1P_2P_3$ to remain unchanged during the motion of the system? That is, under what conditions does the system rotate around the axis σ as a rigid body?

12.20 The more powerful the gravitational force of a planet, the greater its escape speed, v, and the greater the gravitational acceleration, g, at its surface. However, in Table 12.1, the value for v is much greater for Uranus than for Earth—but g is smaller on Uranus than on Earth! How can this be?

12.21 Is the orbital speed of the Earth when it is closest to the Sun greater than, less than, or equal to the orbital speed when it is farthest from the Sun? Explain.

12.22 Point out any flaw in the following physics exam statement: "*Kepler's First Law states that all planets move in elliptical orbits with the Sun at one focal point. It follows that during one complete revolution around the Sun (1 year), the Earth will pass through a closest point to the Sun—the*

perihelion—as well as through a furthest point from the Sun—the aphelion. This is the main cause of the seasons (summer and winter) on Earth."

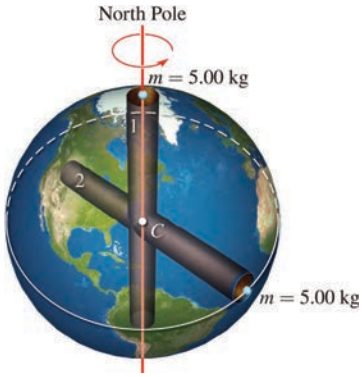
12.23 A comet orbiting the Sun moves in an elliptical orbit. Where is its kinetic energy, and therefore its speed, at a maximum—at perihelion or aphelion? Where is its gravitational potential energy at a maximum?

12.24 Where the International Space Station orbits, the gravitational acceleration is just 11.5% less than its value on the surface of the Earth. Nevertheless, astronauts in the space station float. Why is this so?

12.25 Satellites in low orbit around the Earth lose energy from colliding with the gases of the upper atmosphere, causing them to slowly spiral inward. What happens to their kinetic energy as they fall inward?

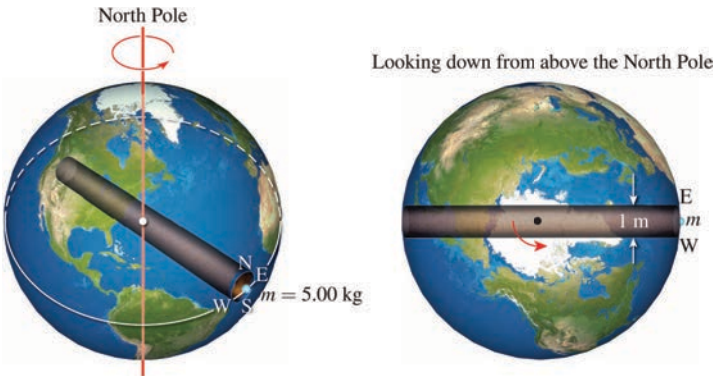
12.26 Compare the magnitudes of the gravitational force that the Earth exerts on the Moon and the gravitational force that the Moon exerts on the Earth. Which is larger?

12.27 Imagine that two tunnels are bored completely through the Earth, passing through the center. Tunnel 1 is along the Earth's axis of rotation, and tunnel 2 is in the equatorial plane, with both ends at the Equator. Two identical balls, each with a mass of 5.00 kg, are simultaneously dropped into the tunnels. Neglect air resistance and friction from the tunnel walls. Do the balls reach the center of the Earth (point *C*) at the same time? If not, which ball reaches the center of the Earth first?

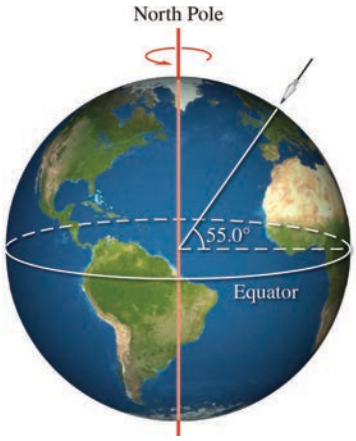


12.28 Imagine that a tunnel is bored in the Earth's equatorial plane, going completely through the center of the Earth with both ends at the Equator. A mass of 5.00 kg is dropped into the tunnel at one end, as shown in the figure. The tunnel has a radius that is slightly larger than that of the mass. The mass is dropped into the center of the tunnel. Neglect air resistance and friction from the tunnel wall. Does the mass ever touch the wall of the tunnel as it falls? If so, which side does it touch first, north, east, south, or west? (*Hint:*

The angular momentum of the mass is conserved if the only forces acting on it are radial.)



12.29 A plumb bob located at latitude 55.0° N hangs motionlessly with respect to the ground beneath it. A straight line from the string supporting the bob does not go exactly through the Earth's center. Does this line intersect the Earth's axis of rotation south or north of the Earth's center?



EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Section 12.1

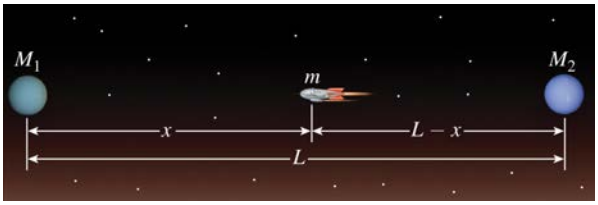
12.30 The Moon causes tides because the gravitational force it exerts differs between the side of the Earth nearer to it and the side farther from it. Find the difference in the accelerations toward the Moon of objects on the nearer and farther sides of the Earth.

12.31 After a spacewalk, a 1.00-kg tool is left 50.0 m from the center of gravity of a 20.0-metric ton space station, orbiting along with it. How much closer to the space station will the tool drift in an hour due to the gravitational attraction of the space station?

•**12.32** a) What is the total force on m_1 due to m_2, m_3, and m_4 if all four masses are located at the corners of a square of side a? Let $m_1 = m_2 = m_3 = m_4$.

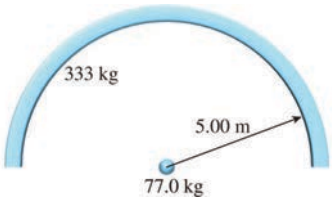
b) Sketch all the forces acting on m_1.

•**12.33** A spaceship of mass m is located between two planets of masses M_1 and M_2; the distance between the two planets is L, as shown in the figure. Assume that L is much larger than the radius of either planet. What is the position, x, of the spacecraft (given as a function of L, M_1, and M_2) if the net force on the spacecraft is zero?

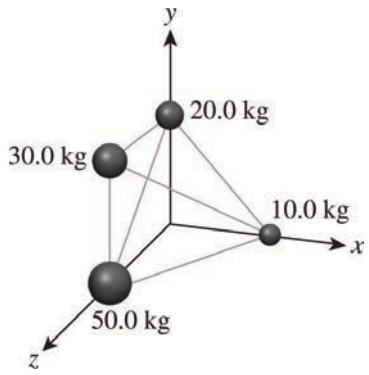


•**12.34** A carefully designed experiment can measure the gravitational force between masses of 1 kg. Given that the density of iron is 7860 kg/m^3, what is the gravitational force between two 1.00-kg iron spheres that are touching?

•• **12.35** A uniform rod of mass 333 kg is in the shape of a semicircle of radius 5.00 m. Calculate the magnitude of the force on a 77.0-kg point mass placed at the center of the semicircle, as shown in the figure.



•• **12.36** The figure shows a system of four masses. The center-to-center distance between any two of the masses is 10.0 cm. The base of the pyramid is in the *xz*-plane and the 20.0-kg mass is on the *y*-axis. What is the magnitude and direction of the gravitational force acting on the 10.0-kg mass? Give direction of the net force with respect to the *xyz*-coordinates shown.



Sections 12.2 and 12.3

12.37 Suppose a new extrasolar planet is discovered. Its mass is double the mass of the Earth, but it has the same density and spherical shape as the Earth. How would the weight of an object at the new planet's surface differ from its weight on Earth?

12.38 What is the magnitude of the free-fall acceleration of a ball (mass m) due to the Earth's gravity at an altitude of $2R$, where R is the radius of the Earth? Ignore the rotation of the Earth.

12.39 Some of the deepest mines in the world are in South Africa and are roughly 3.5 km deep. Consider the Earth to be a uniform sphere of radius 6370 km.

a) How deep would a mine shaft have to be for the gravitational acceleration at the bottom to be reduced by a factor of 2 from its value on the Earth's surface?

b) What is the percentage difference in the gravitational acceleration at the bottom of the 3.5-km-deep shaft relative to that at the Earth's mean radius? That is, what is the value of $(a_{\text{surf}} - a_{3.5\,\text{km}})/a_{\text{surf}}$?

•**12.40** In an experiment performed at the bottom of a very deep vertical mine shaft, a ball is tossed vertically in the air with a known initial velocity of 10.0 m/s, and the maximum height the ball reaches (measured from its launch point) is determined to be 5.113 m. Knowing the radius of the Earth, $R_{\text{E}} = 6370$ km, and the gravitational acceleration at the surface of the Earth, $g(0) = 9.81\text{m/s}^2$, calculate the depth of the shaft.

•• **12.41** Careful measurements of local variations in the acceleration due to gravity can reveal the locations of oil deposits. Assume that the Earth is a uniform sphere of radius 6370 km and density $5500.\ \text{kg/m}^3$, except that there is a spherical region of radius 1.00 km and density $900.\ \text{kg/m}^3$, whose center is at a depth of 2.00 km. Suppose you are standing on the surface of the Earth directly above the anomaly with an instrument capable of measuring the acceleration due to gravity with great precision. What is the fractional deviation of the acceleration due to gravity that you measure compared to what you would have measured had the density been $5500.\ \text{kg/m}^3$, everywhere? (*Hint:* Think of this as a superposition problem involving two uniform spherical masses, one with a negative density.)

Section 12.4

12.42 A spaceship is launched from the Earth's surface with a speed v. The radius of the Earth is R. What will its speed be when it is very far from the Earth?

12.43 What is the ratio of the escape speed to the orbital speed of a satellite at the surface of the Moon, where the gravitational acceleration is about a sixth of that on Earth?

12.44 Standing on the surface of a small spherical moon whose radius is $6.30 \cdot 10^4 \text{m}$ and whose mass is $8.00 \cdot 10^{18} \text{kg}$, an astronaut throws a rock of mass 2.00 kg straight upward with an initial speed 40.0m/s. (This moon is too small to have an atmosphere.) What maximum height above the surface of the moon will the rock reach?

12.45 An object of mass m is launched from the surface of the Earth. Show that the minimum speed required to send the projectile to a height of $4R_\text{E}$ above the surface of the Earth is $v_\text{min} = \sqrt{8GM_\text{E}/5R_\text{E}}$. M_E is the mass of the Earth and R_E is the radius of the Earth. Neglect air resistance.

12.46 For the satellite in Solved Problem 12.3, orbiting the Earth at a distance of $3.75\ R_\text{E}$ with a speed of 4.08 km/s, with what speed would the satellite hit the Earth's surface if somehow it suddenly stopped and fell to Earth? Ignore air resistance.

•**12.47** Estimate the radius of the largest asteroid from which you could escape by jumping. Assume spherical geometry and a uniform density equal to the Earth's average density.

•**12.48** Eris, the largest dwarf planet known in the Solar System, has a radius $R = 1200 \text{ km}$ and an acceleration due to gravity on its surface of magnitude $g = 0.77 \text{ m/s}^2$.

a) Use these numbers to calculate the escape speed from the surface of Eris.

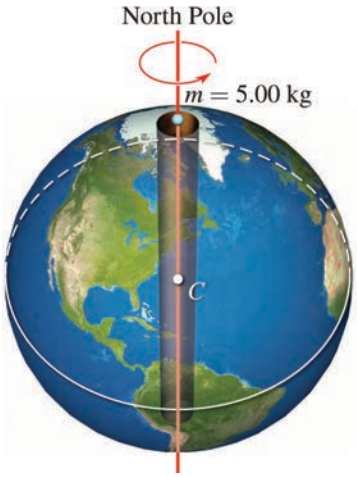
b) If an object is fired directly upward from the surface of Eris with half of this escape speed, to what maximum height above the surface will the object rise? (Assume that Eris has no atmosphere and negligible rotation.)

•**12.49** Two identical 20.0-kg spheres of radius 10.0 cm are 30.0 cm apart (center-to-center distance).

a) If they are released from rest and allowed to fall toward one another, what is their speed when they first make contact?

b) If the spheres are initially at rest and just touching, how much energy is required to separate them to 1.00 m apart? Assume that the only force acting on each mass is the gravitational force due to the other mass.

•• **12.50** Imagine that a tunnel is bored completely through the Earth along its axis of rotation. A ball with a mass of 5.00 kg is dropped from rest into the tunnel at the North Pole, as shown in the figure. Neglect air resistance and friction from the tunnel wall. Calculate the potential energy of the ball as a function of its distance from the center of the Earth. What is the speed of the ball when it arrives at the center of the Earth (point *C*)?



Section 12.5

12.51 The *Apollo 8* mission in 1968 included a circular orbit at an altitude of 111 km above the Moon's surface. What was the period of this orbit? (You need to look up the mass and radius of the Moon to answer this question!)

•**12.52** Halley's comet orbits the Sun with a period of 75.3 yr.

a) Find the semimajor axis of the orbit of Halley's comet in astronomical units (1 AU is equal to the semimajor axis of the Earth's orbit).

b) If Halley's comet is 0.586 AU from the Sun at perihelion, what is its maximum distance from the Sun, and what is the eccentricity of its orbit?

•• **12.53** A satellite of mass m is in an elliptical orbit (that satisfies Kepler's laws) about a body of mass M, with m negligible compared to M.

a) Find the total energy of the satellite as a function of its speed, v, and distance, r, from the body it is orbiting.

b) At the maximum and minimum distance between the satellite and the body, and only there, the angular momentum is simply related to the speed and distance. Use this relationship and the result of part (a) to eliminate v and obtain a relationship between the extreme distance r and the satellite's energy and angular momentum.

c) Solve the result of part (b) for the maximum and minimum radii of the orbit in terms of the energy and angular momentum per unit mass of the satellite.

d) Transform the results of part (c) into expressions for the semimajor axis, a, and eccentricity of the orbit, e, in terms of the energy and angular momentum per unit mass of the satellite.

•• **12.54** Consider the Sun to be at the origin of an xy-coordinate system. A telescope spots an asteroid in the xy-plane at a position given by $\left(2.00 \cdot 10^{11}\ \text{m}, 3.00 \cdot 10^{11}\ \text{m}\right)$ with a velocity given by $\left(-9.00 \cdot 10^{3}\text{m/s}, -7.00 \cdot 10^{3}\text{m/s}\right)$. What will the asteroid's speed and distance from the Sun be at closest approach?

Section 12.6

12.55 A spy satellite was launched into a circular orbit with a height of 700. km above the surface of the Earth. Determine its orbital speed and period.

12.56 Express algebraically the ratio of the gravitational force on the Moon due to the Earth to the gravitational force on the Moon due to the Sun. Why, since the ratio is so small, doesn't the Sun pull the Moon away from the Earth?

12.57 A space shuttle is initially in a circular orbit at a radius of $r = 6.60 \cdot 10^6$ m from the center of the Earth. A retrorocket is fired forward, reducing the total energy of the space shuttle by 10.0% (that is, increasing the magnitude of the negative total energy by 10.0%), and the space shuttle moves to a new circular orbit with a radius that is smaller than r. Find the speed of the space shuttle (a) before and (b) after the retrorocket is fired.

•**12.58** A 200.-kg satellite is in circular orbit around the Earth and moving at a speed of 5.00 km/s. How much work must be done to move the satellite into another circular orbit that is twice as high above the surface of the Earth?

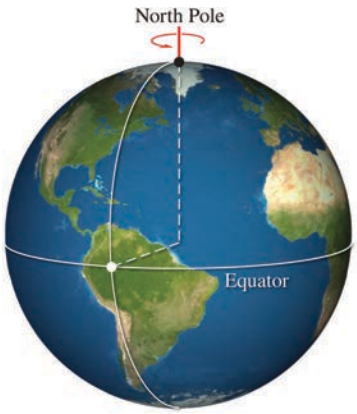
•**12.59** The radius of a black hole is the distance from the black hole's center at which the escape speed is the speed of light.

a) What is the radius of a black hole with a mass twice that of the Sun?

b) At what radius from the center of the black hole in part (a) would the orbital speed be equal to the speed of light?

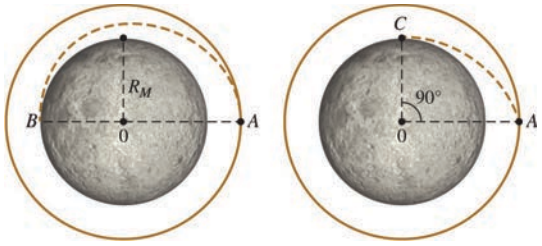
c) What is the radius of a black hole with the same mass as that of the Earth?

•**12.60** A satellite is in a circular orbit around a planet. The ratio of the satellite's kinetic energy to its gravitational potential energy, K/U_g, is a constant whose value is independent of the masses of the satellite and planet and of the radius and velocity of the orbit. Find the value of this constant. (Potential energy is taken to be zero at infinite separation.)



•**12.61** Determine the minimum amount of energy that a projectile of mass 100.0 kg must gain to reach a circular orbit 10.00 km above the Earth's surface if launched from (a) the North Pole or (b) the Equator (keep answers to four significant figures). Do not be concerned about the direction of the launch or of the final orbit. Is there an advantage or disadvantage to launching from the Equator? If so, how significant is the difference? Do not neglect the rotation of the Earth when calculating the initial energies. Use $5.974 \cdot 10^{24}$kg for the mass of the Earth and 6357 km as the radius of the Earth.

•• **12.62** A rocket with mass $M = 12.0$ metric tons is moving around the Moon in a circular orbit at the height of $h = 100.$ km. The braking engine is activated for a short time to lower the orbital height so that the rocket can make a lunar landing. The velocity of the ejected gases is $u = 1.00 \cdot 10^4 \mathrm{m/s}$ relative to the rocket's initial velocity. The Moon's radius is $R_\mathrm{M} = 1.74 \cdot 10^3$ km; the acceleration of gravity near the Moon's surface is $g_\mathrm{M} = 1.62 \mathrm{m/s^2}$.



a) What amount of fuel will be used by the braking engine if it is activated at point *A* of the orbit and the rocket lands on the Moon at point *B* (see the left part of the figure)?

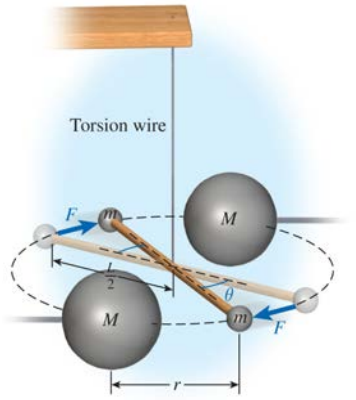
b) Suppose that, at point *A*, the rocket is given an impulse directed toward the center of the Moon, to put it on a trajectory that meets the Moon's surface at point *C* (see the right part of the figure). What amount of fuel is needed in this case?

Additional Exercises

12.63 Calculate the magnitudes of the gravitational forces exerted on the Moon by the Sun and by the Earth when the two forces are in direct competition, that is, when the Sun, Moon, and Earth are aligned with the Moon between the Sun and the Earth. (This alignment corresponds to a solar eclipse.) Does the orbit of the Moon ever actually curve away from the Sun, toward the Earth?

12.64 A projectile is shot vertically from the surface of the Earth by means of a very powerful cannon. If the projectile reaches a height of 55.0 km above Earth's surface, what was the speed of the projectile when it left the cannon?

12.65 Newton's Law of Gravity specifies the magnitude of the interaction force between two point masses, m_1 and m_2, separated by a distance r as $F(r) = Gm_1m_2/r^2$. The gravitational constant G can be determined by directly measuring the interaction force (gravitational attraction) between two sets of spheres by using the apparatus constructed in the late 18th century by the English scientist Henry Cavendish. This apparatus was a torsion balance consisting of a 6.00-ft wooden rod suspended from a torsion wire, with a lead sphere having a diameter of 2.00 in and a weight of 1.61 lb attached to each end. Two 12.0-in, 348-lb lead balls were located near the smaller balls, about 9.00 in away, and held in place with a separate suspension system. Today's accepted value for G is $6.674 \cdot 10^{-11}\text{m}^3\text{kg}^{-1}\text{s}^{-2}$. Determine the force of attraction between the larger and smaller balls that had to be measured by this balance. Compare this force to the weight of the small balls.



12.66 Newton was holding an apple of mass 100. g and thinking about the gravitational forces exerted on the apple by himself and by the Sun. Calculate the magnitude of the gravitational force acting on the apple due to (a) Newton, (b) the Sun, and (c) the Earth, assuming that the distance from the apple to Newton's center of mass is 50.0 cm and Newton's mass is 80.0 kg.

12.67 A 1000.-kg communications satellite is released from a space shuttle to initially orbit the Earth at a radius of $7.00 \cdot 10^6$ m. After being deployed, the satellite's rockets are fired to put it into a higher altitude orbit of radius $5.00 \cdot 10^7$ m. What is the minimum mechanical energy supplied by the rockets to effect this change in orbit?

12.68 Consider a 0.300-kg apple (a) attached to a tree and (b) falling. Does the apple exert a gravitational force on the Earth? If so, what is the magnitude of this force?

12.69 At what height *h* above the Earth will a satellite moving in a circular orbit have half the period of the Earth's rotation about its own axis?

•**12.70** In the Earth-Moon system, there is a point where the gravitational forces balance. Assume that the mass of the Moon is $\frac{1}{81}$ that of the Earth.

a) At what point, on a line between the Earth and the Moon, is the gravitational force exerted on an object by the Earth exactly balanced by the gravitational force exerted on the object by the Moon?

b) Is this point one of stable or unstable equilibrium?

c) Calculate the ratio of the force of gravity due to the Sun acting on an object at this point to the force of gravity due to Earth and, separately, to the force of gravity due to the Moon.

•• **12.71** Consider a particle on the surface of the Earth, at a position with an angle of latitude $\lambda = 30.0^\circ$ N, as shown in the figure. For this problem, assume that the Earth is a sphere with radius $R = 6.37 \cdot 10^6$ m and that $g = 9.81 \text{m/s}^2$. Find (a) the magnitude, and (b) the direction of the effective gravitational force acting on the particle, taking into consideration the rotation of the Earth. (c) What angle λ gives rise to the maximum deviation of the gravitational acceleration?

•**12.72** An asteroid is discovered to have a tiny moon that orbits it in a circular path at a distance of 100. km and with a period of 40.0 h. The

asteroid is roughly spherical (unusual for such a small body) with a radius of 20.0 km.

a) Find the acceleration of gravity at the surface of the asteroid.

b) Find the escape speed from the asteroid.

•12.73

a) By what percentage does the gravitational potential energy of the Earth change between perihelion and aphelion? (Assume that the Earth's potential energy would be zero if it moved to a very large distance away from the Sun.)

b) By what percentage does the kinetic energy of the Earth change between perihelion and aphelion?

•12.74 A planet with a mass of $7.00 \cdot 10^{21}$ kg is in a circular orbit around a star with a mass of $2.00 \cdot 10^{30}$ kg. The planet has an orbital radius of $3.00 \cdot 10^{10}$ m.

a) What is the linear orbital velocity of the planet?

b) What is the period of the planet's orbit?

c) What is the total mechanical energy of the planet?

•12.75 The astronomical unit (AU, equal to the mean radius of the Earth's orbit) is $1.4960 \cdot 10^{11}$ m, and a year is $3.1557 \cdot 10^{7}$ s. Newton's gravitational constant is $G = 6.6738 \cdot 10^{11}\ \mathrm{m^3 kg^{-1} s^{-2}}$. Calculate the mass of the Sun in kilograms. (Recalling or looking up the mass of the Sun does not constitute a solution to this problem.)

•12.76 The distances from the Sun at perihelion and aphelion for Pluto are $4410 \cdot 10^{6}$ km and $7360 \cdot 10^{6}$ km, respectively. What is the ratio of Pluto's orbital speed around the Sun at perihelion to that at aphelion?

•12.77 The weight of a star is usually balanced by two forces: the gravitational force, acting inward, and the force created by nuclear reactions, acting outward. Over a long period of time, the force due to nuclear reactions gets weaker, causing the gravitational collapse of the star and crushing atoms out of existence. Under such extreme conditions, protons and electrons are squeezed to form neutrons, giving birth to a neutron star. Neutron stars are massively heavy—a teaspoon of the substance of a neutron star would weigh 50 million metric tons on the Earth.

a) Consider a neutron star whose mass is twice the mass of the Sun and whose radius is 10.0 km. If it rotates with a period of 1.00 s, what is the speed of a point on the equator of this star? Compare this speed with the speed of a point on Earth's Equator.

b) What is the value of g at the surface of this star?

c) Compare the weight of a 1.00-kg mass on the Earth with its weight on the neutron star.

d) If a satellite is to circle 10.0 km above the surface of such a neutron star, how many revolutions per minute will it make?

e) What is the radius of the geostationary orbit for this neutron star?

•• **12.78** You have been sent in a small spacecraft to rendezvous with a space station that is in a circular orbit of radius $2.5000 \cdot 10^4$ km from the Earth's center. Due to a mishandling of units by a technician, you find yourself in the same orbit as the station but exactly halfway around the orbit from it! You do not apply forward thrust in an attempt to chase the station; that would be fatal folly. Instead, you apply a brief braking force against the direction of your motion, to put you into an elliptical orbit, whose highest point is your present position, and whose period is half that of your present orbit. Thus, you will return to your present position when the space station has come halfway around the circle to meet you. Is the minimum radius from the Earth's center—the low point—of your new elliptical orbit greater than the radius of the Earth (6370 km), or have you botched your last physics problem?

•• **12.79** If you and the space station are initially in a low orbit—say, with a radius of 6720 km, approximately that of the orbit of the International Space Station—the maneuver of Problem 12.78 will fail unpleasantly. Keeping in mind that the life-support capabilities of your small spacecraft are limited and so time is of the essence, can you perform a similar maneuver that will enable you to rendezvous with the station? Find the perihelion, aphelion, and period of the transfer orbit you should use.

•• **12.80** A satellite is placed between the Earth and the Moon, along a straight line that connects their centers of mass. The satellite has an orbital period around the Earth that is the same as that of the Moon, 27.3 days. How far away from the Earth should this satellite be placed?

MULTI-VERSION EXERCISES

12.81 An electromagnetic rail accelerator is used to launch a research probe vertically from the surface of the Moon. The initial speed of the projectile is 114.5m/s. What height does it reach above the surface of the Moon? Assume that the radius of the Moon is 1737 km and the mass of the Moon is $7.348 \cdot 10^{22}$ kg.

12.82 An electromagnetic rail accelerator is used to launch a research probe vertically from the surface of the Moon. The probe reaches a height of 4.905 km above the surface of the Moon. What was the initial speed of the probe? Assume that the radius of the Moon is 1737 km and the mass of the Moon is $7.348 \cdot 10^{22}$ kg.

12.83 A comet orbits the Sun with a period of 89.17 yr. At perihelion, the comet is 1.331 AU from the Sun. How far from the Sun (in AU) is the comet at aphelion?

12.84 A comet orbits the Sun with a period of 98.11 yr. At aphelion, the comet is 41.19 AU from the Sun. How far from the Sun (in AU) is the comet at perihelion?

12.85 A comet orbits the Sun. The aphelion of its orbit is 31.95 AU from the Sun. The perihelion is 1.373 AU. What is the period (in years) of the comet's orbit?

12.86 A spherical asteroid has a mass of $1.869 \cdot 10^{20}$ kg and a radius of 358.9 km. What is the escape speed from its surface?

12.87 A spherical asteroid has a mass of $1.769 \cdot 10^{20}$ kg. The escape speed from its surface is 273.7 m/s. What is the radius of the asteroid?

12.88 A spherical asteroid has a radius of 365.1 km. The escape speed from its surface is 319.2 m/s. What is the mass of the asteroid?

Figure 13.1 shows the Horns Rev offshore wind farm, in the North Sea, 15 km off the west coast of Denmark. When this 80-turbine wind farm went into operation in 2002, it was the largest in the world, with a capacity of 160 MW. Wind turbines can make a great contribution toward satisfying our future needs for electrical power by extracting energy from the wind, which is the motion of the fluid surrounding us—the air in Earth's atmosphere. The turbines in a wind farm cannot be placed too close to one another, because they create downwind wakes, which reduce the efficiency of any turbine in them. A great deal of research effort is currently devoted to studying and modeling these wakes. Normally, the wakes are invisible to the naked eye, but in Figure 13.1 the atmospheric conditions (temperature and water vapor content) were just right for condensation to form cloud streams. Fluid dynamics is currently a major area of research, with applications to all areas of physics from astronomy to nuclear research.

FIGURE 13.1 Horns Rev wind farm in the North Sea. Under the right atmospheric conditions, the wakes of the turbines can become visible when condensation of water vapor in the air creates streams of clouds.

So far, we have studied motion of idealized objects, ignoring factors such as the materials they are made of and the behavior of these materials in response to the forces exerted on them. This chapter considers some of these factors, presenting an overview of the physical characteristics of solids, liquids, and gases.

WHAT WE WILL LEARN

- The atom is the basic building block of macroscopic matter.
- The diameter of an atom is approximately 10^{-10} m.
- Matter can exist as a gas, a liquid, or a solid.
  - A gas is a system in which the atoms move freely through space.
  - A liquid is a system in which the atoms move freely but form a nearly incompressible substance.
  - A solid defines its own size and shape.
- Solids are nearly incompressible.
- Various forms of stress, such as stretching, compression, and shearing, can deform solids. These deformations can be expressed in terms of linear relationships between the applied stress and the resulting deformation.
- Pressure is force per unit area.
- The pressure of the Earth's atmosphere can be measured using a mercury barometer or a similar instrument.
- The pressure of gas can be measured using a mercury manometer.
- Pascal's Principle states that pressure applied to a confined fluid is transmitted to all parts of the fluid.
- Archimedes' Principle states that the buoyant force on an object in a fluid is equal to the weight of the fluid displaced by the object.
- Bernoulli's Principle states that the faster a fluid flows, the less pressure it exerts on its boundary.

13.1 Atoms and the Composition of Matter

During the evolution of physics, scientists have explored ever smaller dimensions, looking deeper into matter in order to examine its elementary building blocks. This general way of learning more about a system by studying its subsystems is called *reductionism* and has proven a fruitful guiding principle during the last four or five centuries of scientific advancements.

Today, we know that **atoms** are the basic building blocks of matter, although they themselves are composite particles. The substructure of atoms, however, can be resolved only with accelerators and other tools of modern nuclear and particle physics. For the purposes of this chapter, it is reasonable to view atoms as the elementary building blocks. In fact, the word *atom* comes from the Greek *atomos*, which means "indivisible." The diameter of an atom is about 10^{-10} m $= 0.1$ nm. This distance is often called an angstrom (Å).

The simplest atom is hydrogen, composed of a proton and an electron. Hydrogen is the most abundant element in the universe. The next most abundant element is helium. Helium has two protons and two neutrons in its nucleus, along with two electrons surrounding the nucleus. Another common atom is oxygen, with eight protons and eight electrons, as well as (usually) eight neutrons. The heaviest naturally occurring atom is uranium, with 92 protons, 92 electrons, and usually 146 neutrons. So far, 118 different elements have been recognized and classified in the periodic table of the elements.

Essentially all of the hydrogen in the universe, along with some helium, was produced in the Big Bang about 13.7 billion years ago. Heavier elements, up to iron, were and still are produced in stars. Elements with more protons and neutrons than iron (gold, mercury, lead, and so forth) are thought to have been produced by supernova explosions. Most of the atoms of the elements on Earth were produced more than 5 billion years ago, probably in a supernova explosion, and have been recycled ever since. Even our bodies are composed of atoms from the ashes of a dying star. (The production and recycling of the elements will be covered in detail in Chapters 39 and 40.)

Consider the number of atoms in 12 g of the most common isotope of carbon, ^{12}C, where 12 represents the atomic mass number—that is, the total number of protons (six) plus neutrons (six) in the carbon nucleus. This number of atoms has been measured to be $6.022 \cdot 10^{23}$, which is called **Avogadro's number,** N_{A}:

$$N_{\text{A}} = 6.022 \ \cdot 10^{23}.$$

To get a feeling for how much carbon corresponds to N_{A} atoms, consider two forms of carbon: diamond and graphite. Diamonds are composed of carbon

atoms arranged in a crystal lattice, whereas the carbon atoms in graphite are arranged in two-dimensional layers (Figure 13.2). In the diamond structure, carbon atoms are bonded in an interlocking lattice, which makes diamond very hard and transparent to light. In graphite, carbon atoms are arranged in layers that can slide over one another, making graphite soft and slippery. It does not reflect light, but appears black instead. Graphite is used in pencils and for lubrication.

b: Denis Vrublevski/Shutterstock; **d:** Perry Mastrovito/Image Source/Getty Images

The density of diamond is $3.51\ \mathrm{g/cm^3}$, and the density of graphite is $2.20\ \mathrm{g/cm^3}$. Masses of diamonds are usually given in carats, where $1\ \mathrm{carat} = 200\ \mathrm{mg}$. A 12-g diamond would have N_A atoms, a mass of 60 carats, and a volume of about $3.4\ \mathrm{cm^3}$, about 1.3 times bigger than the Hope Diamond. A typical wedding ring might have a 1-carat diamond containing approximately 10^{22} carbon atoms.

New structures composed entirely of carbon atoms have been produced; these include fullerenes and carbon nanotubes. Fullerenes are composed of 60 carbon atoms arranged in a truncated icosahedron, a shape like a soccer ball, as illustrated in Figure 13.3a. The 1996 Nobel Prize in Chemistry was awarded to Robert Curl, Harold Kroto, and Richard Smalley for their discovery of fullerenes. Fullerenes are also called *buckyballs* and were named after Buckminster Fuller (1895–1983), who invented the geodesic dome, whose geometry resembles that of the fullerenes. Figure 13.3b shows the structure of a carbon nanotube, consisting of interlocking hexagons of carbon atoms. A carbon nanotube can be thought of as a layer of graphite (Figure 13.2c) rolled up into a tube. Fullerenes and carbon nanotubes are early products of an emerging area of research termed *nanotechnology*, referring to the size of the objects under investigation. New materials constructed using nanotechnology may revolutionize materials science. For example, fullerene crystals are harder than diamonds, and fibers composed of carbon nanotubes are lightweight and

stronger than steel. And carbon has still other potentially useful forms. In 2004, Andre Geim and Konstantin Novoselov discovered graphene, a two-dimensional sheet of carbon atoms arranged in a hexagonal lattice structure (Figure 13.2e). They received the 2010 Nobel Prize in Physics for their discovery of this material, which holds great promise for electronics applications.

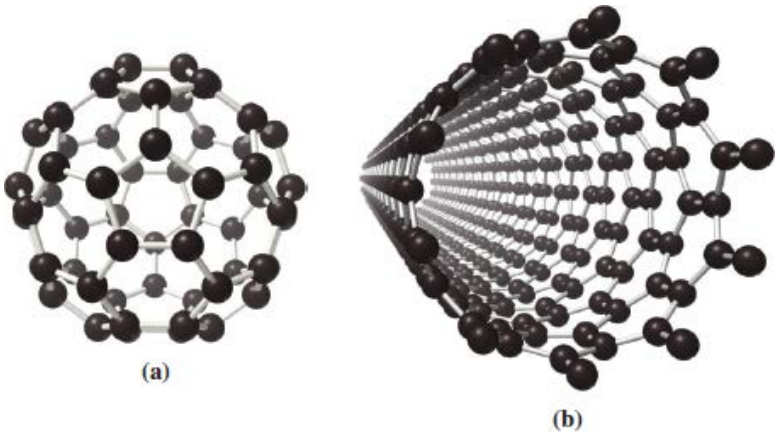

FIGURE 13.3 Nanostructures consisting of arrangements of carbon atoms: (a) fullerene, or buckyball; (b) carbon nanotube.

One **mole** (mol) of a substance contains $N_A = 6.022 \cdot 10^{23}$ atoms or molecules. Because the masses of a proton and a neutron are about equal and the mass of either is far greater than that of an electron, the mass of 1 mol of a substance in grams is given by the atomic mass number. Thus, 1 mol of ^{12}C has a mass of 12 g, and 1 mol of ^{4}He has a mass of 4 g. The periodic table of the elements lists the atomic mass number for each element. This atomic mass number is equal to the number of protons and neutrons contained in the nucleus of the atom; it is not an integer because it takes into account the natural isotopic abundances. (Isotopes of an element have varying numbers of neutrons in the nucleus. If a carbon nucleus has seven neutrons, it is the ^{13}C isotope.) For molecules, the molar mass is obtained by adding the mass numbers of all atoms in the molecule. Thus, 1 mol of water, $^{1}H_2{}^{16}O$, has a mass of 18.02 g. (It is not exactly 18 g, because 0.2% of oxygen atoms are the isotope ^{18}O.)

Self-Test Opportunity 13.1

How many molecules of water are in a half-liter bottle of water? The mass of 1 mol of water is 18.02 g.

Self-Test Opportunity 13.2

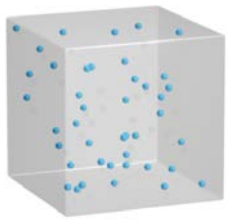
One mole of any gas occupies a volume of 22.4 L at standard temperature and pressure (STP, or $T = 0\ ^{\circ}\text{C}$ and $p = 1\ \text{atm}$). What are the densities of hydrogen gas and helium gas?

Atoms are electrically neutral. They have the same number of positively charged protons as negatively charged electrons. The chemical properties of an atom are determined by its electronic structure. This structure allows bonding of certain atoms with other atoms to form molecules. For example, water is a molecule containing two hydrogen atoms and one oxygen atom. The electronic structures of atoms and molecules determine a substance's macroscopic properties, such as whether it exists as a gas, liquid, or solid at a given temperature and pressure.

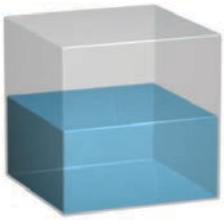
13.2 States of Matter

A **gas** is a system in which each atom or molecule moves through space as a free particle. Occasionally, an atom or molecule collides with another atom or molecule or with the wall of the container. A gas can be treated as a **fluid** because it can flow and exert pressure on the walls of its container. A gas is compressible, which means that the volume of the container can be changed and the gas will still fill the volume, although the pressure it exerts on the walls of the container will change.

In contrast to gases, most liquids are nearly incompressible. If a gas is placed in a container, it will expand to fill the container (Figure 13.4a). When a **liquid** is placed in a container, it fills only the volume corresponding to its initial volume (Figure 13.4b). If the volume of the liquid is less than the volume of the container, the container is only partially filled.



(a)



(b)

(c)

FIGURE 13.4 (a) A cubical container filled with a gas; (b) the same container partially filled with a liquid; (c) a solid, which does not need a container.

A **solid** does not require a container but instead defines its own shape (Figure 13.4c). Like liquids, solids are nearly incompressible. However, solids can be compressed and deformed slightly.

The categorization of matter into solids, liquids, and gases does not cover the entire range of possibilities. Clearly, which state a certain substance is in depends on its temperature. Water, for example, can be ice (solid), water (liquid), or steam (gas). The same condition holds true for practically all other substances. However, there are states of matter that do not fit into the solid/liquid/gas classification. Matter in stars, for example, is not in any of those three states. Instead, it forms a *plasma,* a system of ionized atoms. On Earth, many beaches are made of sand, a prime example of a *granular medium*. The grains of granular media are solids, but their macroscopic characteristics can be closer to those of liquids (Figure 13.5). For instance, sand can flow like a liquid. *Glasses* seem to be solids at first glance, because they do not change their shape. However, there is also some justification to the view that glass is a type of liquid with an extremely high viscosity. For the purposes of a classification of matter into states, a glass is neither a solid nor a liquid, but a separate state of matter. *Foams* and *gels* are yet other states of matter, which are currently receiving a lot of interest from researchers. In a foam, the material forms thin membranes around enclosed bubbles of gas of different sizes; thus, some foams are very rigid while having a very low mass density.

(a) (b)

FIGURE 13.5 (a) Pouring molten steel (a solid metal at room temperature); (b) pouring sand (a granular medium).

a: HadelProductions/iStock/Getty Images; **b:** Don Farrall/Getty Images

Less than two decades ago, the existence of a new form of matter called *Bose-Einstein* condensates was experimentally verified. An understanding of this new state of matter requires some basic concepts of quantum physics. However, in basic terms, at very low temperatures, a gas of certain kinds of atoms can assume an ordered state in which all of the atoms tend to have the same energy and momentum, very similar to the way that light assumes an ordered state in a laser (see Chapter 38).

Finally, the matter in our bodies and in most other biological organisms does not fit into any of these classifications. Biological tissue consists predominantly of water, yet it is able to keep or change its shape, depending on the environmental boundary conditions.

13.3 Tension, Compression, and Shear

Let's examine how solids respond to external forces.

Elasticity of Solids

Many solids are composed of atoms arranged in a three-dimensional crystal lattice in which the atoms have a well-defined equilibrium distance from their neighbors. Atoms in a solid are held in place by interatomic forces that can be modeled as springs. The lattice is very rigid, which implies that the imaginary springs are very stiff. Macroscopic solid objects such as wrenches and spoons are composed of atoms arranged in such a rigid lattice. However, other solid objects, such as rubber balls, are composed of atoms arranged in long chains rather than in a well-defined lattice. Depending on their atomic or molecular structure, solids can be extremely rigid or more easily deformable.

All rigid objects are somewhat elastic, even though they do not appear to be. Compression, pulling, or twisting can deform a rigid object. If a rigid object is deformed a small amount, it will return to its original size and shape when the deforming force is removed. If a rigid object is deformed past a point called its **elastic limit,** it will not return to its original size and shape but will remain permanently deformed. If a rigid object is deformed too far beyond its elastic limit, it will break.

Stress and Strain

Deformations of solids are usually classified into three types: stretching (or tension), compression, and shear. Examples of stretching, compression, and shear are shown in Figure 13.6. What these three deformations have in common is that a **stress,** or deforming force per unit area, produces a **strain,** or unit deformation. **Stretching,** or **tension,** is associated with tensile stress. **Compression** can be produced by hydrostatic stress. **Shear** is produced by shearing stress, sometimes also called *deviatory stress*. When a shear force is applied, planes of material parallel to the force and on either side of it remain parallel but shift relative to each other.

(a)

(b)

(c)

FIGURE 13.6
Three examples of stress and strain: (a) the stretching of power lines; (b) the compression of the Hoover Dam; (c) shearing by scissors.

a: Malcolm Fife/age fotostock; **b:** Jacobs Stock Photography/Getty Images; **c:** Comstock Images/Alamy Stock Photo

Although stress and strain take different forms for the three types of deformation, they are related linearly through a constant called the **modulus of elasticity:**

$$\text{stress} = \text{modulus of elasticity} \cdot \text{strain}. \tag{13.1}$$

This empirical relationship applies as long as the elastic limit of the material is not exceeded.

In the case of tension, a force F is applied to opposite ends of an object of length L and the object stretches to a new length, $L + \Delta L$ (Figure 13.7). The stress for stretching or tension is defined as the force, F, per unit area, A, applied to the end of an object. The strain is defined as the fractional change in length of the object, $\Delta L/L$. The relationship between stress and strain up to the elastic limit is then

$$\frac{F}{A} = Y\frac{\Delta L}{L}, \tag{13.2}$$

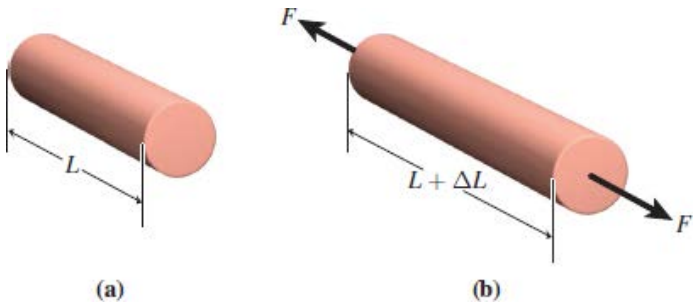


FIGURE 13.7 Tension applied to opposite ends of an object by a pulling force. (a) Object before force is applied. (b) Object after force is applied. Note: Tension can also be applied by pushing, with a resulting negative change in length (not shown).

where Y is called **Young's modulus** and depends only on the type of material and not on its size or shape. Some typical values of Young's modulus are given in Table 13.1.

Table 13.1 Some typical Values of Young's Modulus

Material	Young's Modulus $\left(10^9 \text{N/m}^2\right)$
Aluminum	70
Bone	10–20
Concrete	20–30 (compression)
Diamond	1000–1200
Glass	70
Polystyrene	3
Rubber	0.01–0.1
Steel	200
Titanium	100–120
Tungsten	400
Wood	10–15

Linear compression can be treated in a manner similar to stretching for most materials, within the elastic limits. However, many materials have different breaking points for stretching and compression. The most notable example is concrete, which resists compression much better than stretching, which is why steel rods are added to it in places where greater tolerance of stretching is required. A steel rod resists stretching much better than compression, under which it can buckle.

The stress related to volume compression is caused by a force per unit area applied to the entire surface area of an object for example, one submerged in a liquid (Figure 13.8). The resulting strain is the fractional change in the volume of the object, $\Delta V/V$. The modulus of elasticity in this case is the **bulk modulus,** B. We can thus write the equation relating stress and strain for volume compression as

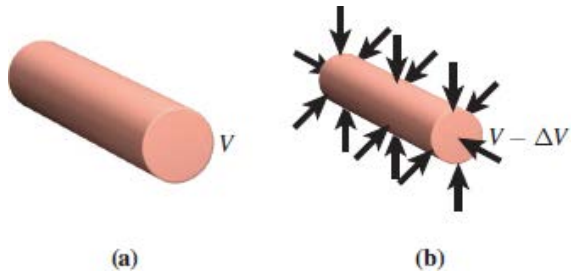

FIGURE 13.8 Compression of an object by fluid pressure; (a) object before compression; (b) object after compression.

$$\frac{F}{A} = B\frac{\Delta V}{V}. \tag{13.3}$$

Some typical values of the bulk modulus are given in Table 13.2. Note the extremely large jump in the bulk modulus from air, which is a gas and can be compressed rather easily, to liquids such as gasoline and water. Solids such as rocks and metals have values for the bulk modulus that are higher than those of liquids by a factor between 5 and 100.

Table 13.2 Some Typical Values of the Bulk Modulus

Material	Bulk Modulus $\left(10^9 \text{N/m}^2\right)$
Air	0.000142
Aluminum	76
Basalt rock	50–80
Gasoline	1.5
Granite rock	10–50
Mercury	28.5
Steel	160
Water	2.2

In the case of shearing, the stress is again a force per unit area. However, for shearing, the force is parallel to the area rather than perpendicular to it (Figure 13.9). For shearing, stress is given by the force per unit area, F/A,

exerted on the end of the object. The resulting strain is given by the fractional deflection of the object, $\Delta x/L$. The stress is related to the strain through the **shear modulus,** G:

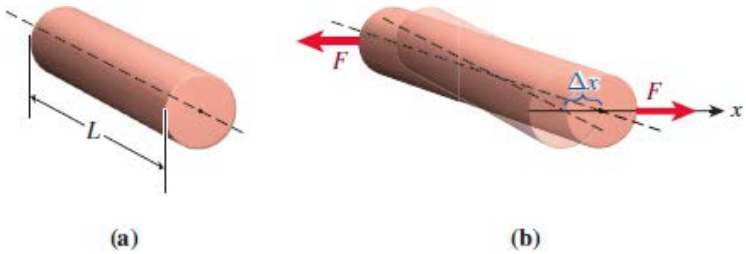

FIGURE 13.9 Shearing of an object caused by a force parallel to the area of the end of the object. (a) Object before shear force is applied. (b) Object after shear force is applied.

$$\frac{F}{A} = G\frac{\Delta x}{L}. \tag{13.4}$$

Some typical values of the shear modulus are given in Table 13.3.

Table 13.3 Some Typical Values of Shear Modulus

Material	Shear Modulus $\left(10^9 \text{N/m}^2\right)$
Aluminum	25
Copper	45
Glass	26
Polyethylene	0.12
Rubber	0.0003
Titanium	41
Steel	70–90

EXAMPLE 13.1 Wall Mount for a Flat-panel TV

You've just bought a new flat-panel TV (Figure 13.10) and want to mount it on the wall with four bolts, each with a diameter each of 0.50 cm. You cannot mount the TV flush against the wall but have to leave a 10.0-cm gap between wall and TV for air circulation.

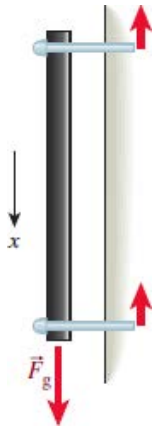

FIGURE 13.10
Forces acting on a wall mount for a flat-panel TV.

PROBLEM 1

If the mass of your new TV is 42.8 kg, what is the shear stress on the bolts?

SOLUTION 1

The combined cross-sectional area of the bolts is

$$A = 4\left(\frac{\pi d^2}{4}\right) = \pi(0.005\ \text{m})^2 = 7.85 \cdot 10^{-5}\ \text{m}^2.$$

One force acting on the bolts is $\vec{F}_g$, the force of gravity on the TV, exerted at one end of each bolt. This force is balanced by a force due to the wall, acting on the other end of the bolts. This wall force holds the TV in place; thus, it has exactly the same magnitude as the force of gravity but points in the opposite direction. Therefore, the force entering into equation 13.4 for the stress is

$$F = mg = (42.8\ \text{kg})\left(9.81\ \ \text{m/s}^2\right) = 420.\ \ \text{N}.$$

Thus, we obtain the shear stress on the bolts:

$$\frac{F}{A} = \frac{420.\ \text{N}}{7.85 \cdot 10^{-5}\text{m}^2} = 5.35 \cdot 10^6\ \text{N/m}^2.$$

PROBLEM 2

The shear modulus of the steel used in the bolts is $9.0 \cdot 10^{10}\ \text{N/m}^2$. What is the resulting vertical deflection of the bolts?

SOLUTION 2

Solving equation 13.4 for the deflection, Δx, we find

$$\Delta x = \left(\frac{F}{A}\right)\frac{L}{G} = \left(5.35 \cdot 10^6\ \text{N/m}^2\right)\frac{0.1\ \text{m}}{9.0 \cdot 10^{10}\ \text{N/m}^2} = 5.94 \cdot 10^{-6}$$

Even though the shear stress is more than 5 million N/m^2, the resulting sag of your flat-panel TV is only about 0.006 mm, a distance that is undetectable with the naked eye.

SOLVED PROBLEM 13.1 Stretched Wire

PROBLEM

A 1.50-m-long steel wire with a diameter of 0.400 mm is hanging vertically. A spotlight of mass $m = 1.50$ kg is attached to the wire and released. How much does the wire stretch?

SOLUTION

THINK

From the diameter of the wire, we can get its cross-sectional area. The weight of the spotlight provides a downward force. The stress on the wire is the weight divided by the cross-sectional area. The strain is the change in the length of the wire divided by its original length. The stress and strain are related through Young's modulus for steel.

SKETCH

Figure 13.11 shows the wire before and after the spotlight is attached.

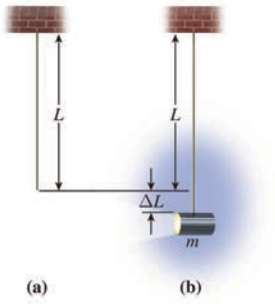

FIGURE 13.11 A wire (a) before and (b) after a spotlight is attached to it.

RESEARCH

The cross-sectional area of the wire, A, can be calculated from the diameter, d, of the wire:

$$A = \pi\left(\frac{d}{2}\right)^2 = \frac{\pi d^2}{4}. \qquad \text{(i)}$$

The force on the wire is the weight of the searchlight,

$$F = mg. \qquad \text{(ii)}$$

We can relate the stress and the strain on the wire through Young's modulus, Y, for steel:

$$\frac{F}{A} = Y\frac{\Delta L}{L}, \qquad \text{(iii)}$$

where ΔL is the change in the length of the wire and L is its original length.

SIMPLIFY

We can combine equations (i), (ii), and (iii) to get

$$\frac{F}{A} = \frac{mg}{\left(\frac{1}{4}\pi d^2\right)} = \frac{4mg}{\pi d^2} = Y\frac{\Delta L}{L}.$$

Solving for the change in the wire's length, we obtain

$$\Delta L = \frac{4mgL}{Y\pi d^2}.$$

CALCULATE

Putting in the numerical values gives us

$$\Delta L = \frac{4mgL}{Y\pi d^2} = \frac{4(1.50\ kg)\left(9.81\ \text{m/s}^2\right)(1.50\ \text{m})}{\left(200\cdot 10^9\ \text{N/m}^2\right)\pi\left(0.400\cdot 10^{-3}\ \text{m}\right)^2} = 0.0008782$$

ROUND

We report our result to three significant figures:

$$\Delta L = 0.000878\ \text{m} = 0.878\ \ \text{mm}.$$

DOUBLE-CHECK

An easy and important first check of a result is to confirm that the units are right. The change in length, which we have calculated, has the units of millimeters, which makes sense. Next, we examine the magnitude: The wire stretches just less than 1 mm compared with its original length of 1.50 m. This stretch is less than 0.1%, which seems reasonable. Any time a steel wire experiences noticeable stretch, breaking of the wire becomes a concern. This is not the case here, which gives us some confidence that our result is of approximately the right order of magnitude.

As noted earlier, the stress applied to an object is proportional to the strain as long as the elastic limit of the material is not exceeded. Figure 13.12 shows a typical stress-strain diagram for a ductile (easily drawn into a wire) metal under tension. Up to the proportional limit, the ductile metal responds linearly to stress. If the stress is removed, the material will return to its original length. If stress is applied past the proportional limit, the material will continue to lengthen until it reaches its yield point. If stress is applied between the proportional limit and the fracture point and then is removed, the material will not return to its original length but will be permanently deformed. The yield point is the point where the stress causes sudden deformation without any increase in force as can be seen from the flattening of the curve (see Figure 13.12). Additional stress will continue to stretch the material until it reaches its fracture point, where it breaks. This breaking stress is also called the *ultimate stress*, or in the case of tension, the *tensile strength*. Some approximate breaking stresses are given in Table 13.4.

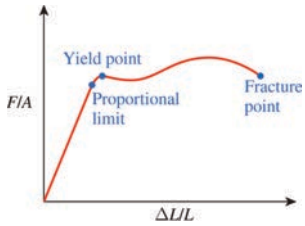

FIGURE 13.12 A typical stress-strain diagram for a ductile metal under tension showing the proportional limit, the yield point, and the fracture point.

Table 13.4 Breaking Stress for Common Materials

Material	Breaking Stress $\left(10^6 \text{N/m}^2\right)$
Aluminum	455
Brass	550
Copper	220
Steel	400
Bone	130

Note that these values are approximate.

13.4 Pressure

This section examines the properties of liquids and gases, together termed *fluids*. The properties of stress and strain, discussed in Section 13.3, are most useful when studying solids, because substances that flow, such as liquids and gases, offer little resistance to shear or tension. In this section, we consider the properties of fluids at rest. Later in this chapter, we will discuss the properties of fluids in motion.

The **pressure**, p, is the force per unit area:

$$p = \frac{F}{A}. \tag{13.5}$$

Pressure is a scalar quantity. The SI unit of pressure is $\mathrm{N/m^2}$, which has been named the **pascal,** abbreviated Pa:

$$1\ \mathrm{Pa} \equiv \frac{1\ \mathrm{N}}{1\ \mathrm{m^2}}.$$

Page 403

The average pressure of the Earth's atmosphere at sea level, 1 atm, is a commonly used non-SI unit that is expressed in other units as follows:

$$1\ \mathrm{atm} = 1.01 \cdot 10^5\ \mathrm{Pa} = 760.\ \mathrm{torr} = 14.7\ \mathrm{lb/in^2}.$$

Gauges used to measure how much air has been removed from a vessel are often calibrated in *torr*, a unit named after the Italian physicist Evangelista Torricelli (1608–1647). Automobile tire pressures in the United States are often measured in pounds per square inch ($\mathrm{lb/in^2}$, or psi).

Concept Check 13.1

Suppose you have a jar of nuts that has been vacuum packed to preserve the contents. You turn the lid and hear a whoosh. Which of the following statements correctly describes the force exerted by the atmosphere on the lid before and after you turn it?

a) The atmosphere exerts more force on the lid before the lid is turned than after it is turned.

b) The atmosphere exerts less force on the lid after the lid is turned than before it is turned.

c) The atmosphere exerts the same force on the lid before and after the lid is turned.

d) There is no way to tell what happens to the force exerted by the atmosphere on the lid when it is turned.

SOLVED PROBLEM 13.2 Weighing Earth's Atmosphere

The Earth's atmosphere is composed (by volume) of 78.08% nitrogen (N_2), 20.95% oxygen (O_2), 0.93% argon (Ar), 0.25% water vapor (H_2O), and traces of other gases, most importantly, carbon dioxide (CO_2). The CO_2 content of the atmosphere is currently (year 2022) around $0.042\% = 420$ ppm (parts per million), but it varies with the seasons by about 6–7 ppm and has been rising since the start of the Industrial Revolution, mainly as a result of the burning of fossil fuels. Approximately 2 ppm of CO_2 are being added to the atmosphere each year.

PROBLEM

What is the mass of the Earth's atmosphere, and what is the mass of 1 ppm of atmospheric CO_2?

SOLUTION

THINK

At first glance, this problem seems rather daunting because very little information is given. However, we know that the atmospheric pressure is $1.01 \cdot 10^5$ Pa and that pressure is force per area.

SKETCH

The sketch in Figure 13.13 shows a column of air with weight mg above an area A of Earth's surface. This air exerts a pressure, p, on the surface.

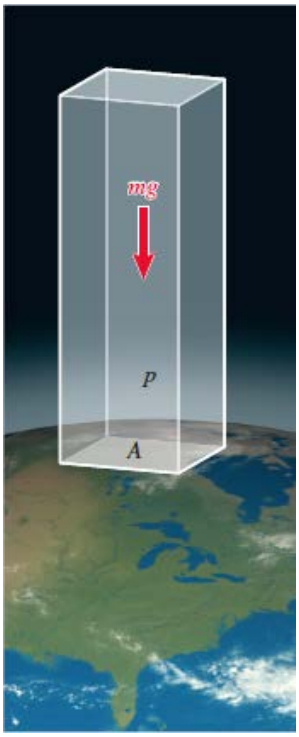

FIGURE 13.13
Weight of the atmosphere.

RESEARCH

We start with the relationship between pressure and force, $p = F/A$, where the area is the surface area of Earth, $A = 4\pi R^2$, and $R = 6370$ km is the radius of Earth. For the force, we can use the atmospheric weight, $F = mg$, where m is the mass of the atmosphere.

SIMPLIFY

We combine the equations just mentioned

$$p = \frac{F}{A} = \frac{mg}{4\pi R^2}$$

and solve for the mass of the atmosphere

$$m = \frac{4\pi R^2 p}{g}.$$

CALCULATE

We substitute the numerical values:

$$m = 4\pi\left(6.37 \cdot 10^6 \text{ m}\right)^2\left(1.01 \cdot 10^5 \text{ Pa}\right)/\left(9.81 \text{ m/s}^2\right) = 5.24978 \cdot 10^{18}$$

ROUND

We round to three significant figures and obtain

$$m = 5.25 \cdot 10^{18} \text{ kg}.$$

DOUBLE-CHECK

In order to obtain the mass of 1 ppm of CO_2 in the atmosphere, we have to realize that the molar mass of CO_2 is $12 + (2.16) = 44$ g. The average mass of a mole of the atmosphere is approximately $0.78(2.14) + 0.21(2.16) + 0.01(40) = 28.96$ g. The mass of 1 ppm of CO_2 in the atmosphere is therefore

$$m_{1 \text{ ppm } CO_2} = 10^{-6} \cdot \ m\frac{44}{28.96} = 7.97 \cdot 10^{12} \text{ kg} = 8.0 \text{ billion tons}.$$

Humans add approximately 2 ppm of CO_2 to the atmosphere each year by burning fossil fuels, which amounts to approximately 16 billion tons of CO_2, a scary number. For comparison, the combined mass of all 8 billion humans on the planet is approximately 0.5 billion tons. Humans add more than 30 times our own weight in carbon dioxide to the atmosphere each year. It is not easy to double-check the orders of magnitude for this calculation. However, data published by the U.S. Energy Information Administration show that total carbon dioxide emissions from burning fossil fuels are currently approximately 30 billion tons per year, higher than our result by a factor of 2. Where does the other half of the CO_2 go? Mainly, it dissolves in the Earth's oceans.

Pressure-Depth Relationship

Consider a tank of water open to the Earth's atmosphere, and imagine a cube of the water inside of it (shown in pink in Figure 13.14). Assume that the top surface of the cube is horizontal and at a depth of y_1 and that the bottom surface of the cube is horizontal and at a depth of y_2. The other sides of the cube are oriented vertically. The water pressure acting on the cube produces forces. However, by Newton's First Law, there must be no net force acting on this stationary cube of water. The forces acting on the vertical sides of the cube clearly cancel out. The vertical forces acting on the bottom and top sides of the cube must also add to zero:

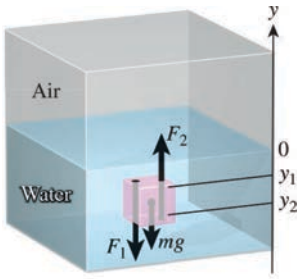

FIGURE 13.14
Cube of water in a tank of water.

$$F_2 - F_1 - mg = 0, \tag{13.6}$$

where F_1 is the force downward on the top of the cube, F_2 is the force upward on the bottom of the cube, and mg is the weight of the cube of water. The pressure at depth y_1 is p_1, and the pressure at depth y_2 is p_2. We can write the forces at these depths in terms of the pressures, assuming that the area of the top and bottom surfaces of the cube is A:

$$F_1 = p_1 A$$
$$F_2 = p_2 A.$$

We can also express the mass, m, of the water in terms of the density of water, ρ (assumed to be constant), and the volume, V, of the cube, $m = \rho V$. Substituting for F_1, F_2, and m in equation 13.6 gives

$$p_2 A - p_1 A - \rho V g = 0.$$

Rearranging this equation and substituting $A(y_1 - y_2)$ for V, we get

$$p_2 A = p_1 A + \rho A(y_1 - y_2)g.$$

Dividing out the area yields an expression for the pressure as a function of depth in a liquid of uniform density ρ:

$$p_2 = p_1 + \rho g(y_1 - y_2). \tag{13.7}$$

A common problem involves the pressure as a function of depth below the surface of a liquid. Starting with equation 13.7, we can define the pressure at the surface of the liquid $(y_1 = 0)$ to be p_0 and the pressure at a given depth $h(y_2 = -h)$ to be p. These assumptions lead to the following expression for the pressure at a given depth of a liquid with uniform density ρ:

$$p = p_0 + \rho g h. \tag{13.8}$$

Note that in deriving equation 13.8, we made use of the fact that the density of the fluid does not change as a function of depth. This assumption of incompressibility is essential for obtaining this result. Later in this section, relaxing this incompressibility requirement will lead to a different formula relating height and pressure for gases. Further, it is important to note that equation 13.8 specifies the pressure in a liquid at a vertical depth of h, without any dependence on horizontal position. Thus, the equation holds regardless of the shape of the vessel containing the liquid. Figure 13.15, for example, shows three connected columns containing a fluid. You can see that the fluid reaches the same height in each column, independent of the shape or cross-sectional area; this occurs because the bottoms are interconnected and thus have the same pressure.

FIGURE 13.15
Three connected columns—the fluid rises to the same height in each.

W. Bauer and G. D. Westfall

EXAMPLE 13.2 Submarine

A U.S. Navy submarine of the Los Angeles class is 110 m long and has a hull diameter of 10. m (Figure 13.16). Assume that the submarine has a flat top with an area of $A = 1100\ \text{m}^2$ and that the density of seawater is $1024\ \text{kg/m}^3$.

FIGURE 13.16 Submarine traveling at the surface of the water.

StockTrek/SuperStock

PROBLEM

What is the total force pushing down on the top of this submarine at a diving depth of 250. m?

Page 405

SOLUTION

The pressure inside the submarine is normal atmospheric pressure, p_0. According to equation 13.8, the pressure at a depth of 250. m is given by $p = p_0 + \rho g h$. Therefore, the pressure difference between the inside and the outside of the submarine is

$$\Delta p = \rho g h = \left(1024\ \ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)(250\ \text{m}) = 2.51 \cdot 10^6\ \text{N/m}^2$$

or approximately 25 atm.

Multiplying the area times the pressure gives the total force, according to equation 13.5. Thus, we find a total force of

$$F = \Delta p A = \left(2.51\ \cdot 10^6\ \text{N/m}^2\right)\left(1100\ \text{m}^2\right) = 2.8\ \cdot 10^9\ \text{N}.$$

This number is astonishingly large and corresponds to the weight of a mass of $\approx$ 280,000 metric tons, over 40 times the submarine's own weight!

Concept Check 13.2

Three containers of water have different shapes, as shown below. The distance between the top surface of the water and the bottom of each container is the same. Which of the following statements correctly characterizes the pressure at the bottom of the containers?

a) The pressure at the bottom of container 1 is the highest.

b) The pressure at the bottom of container 2 is the highest.

c) The pressure at the bottom of container 3 is the highest.

d) The pressure at the bottom of all three containers is the same.

Gauge Pressure and Barometers

The pressure p in equation 13.8 is an **absolute pressure,** which means it includes the pressure of the liquid as well as the pressure of the air above it. The difference between an absolute pressure and the atmospheric air pressure is called a **gauge pressure.** For example, a gauge used to measure the air pressure in a tire is calibrated so that the atmospheric pressure reads zero. When connected to the tire's compressed air, the gauge measures the additional pressure present in the tire. In equation 13.8, the gauge pressure is ρgh.

A simple device used to measure atmospheric pressure is the mercury **barometer** (Figure 13.17). You can construct a mercury barometer by taking a long glass tube, closed at one end, filling it with mercury, and inverting it with the open end in a dish of mercury. The space above the mercury is a vacuum and thus has zero pressure. The difference in height between the top of the mercury in the tube and the top of the mercury in the dish, h, can be related to the atmospheric pressure, p_0, using equation 13.7 with $p_2 = p_1 + \rho g(y_1 - y_2), y_2 - y_1 = h, p_2 = 0$, and $p_1 = p_0$:

$$p_0 = \rho gh.$$

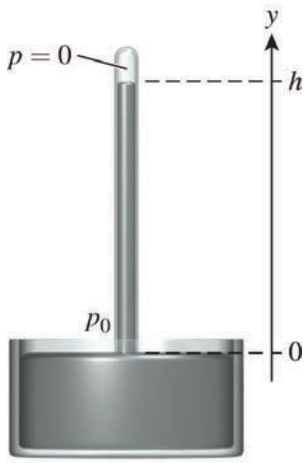

FIGURE 13.17 A mercury barometer measures atmospheric pressure, p_0.

Note that the measurement of atmospheric pressure using a mercury barometer depends on the local value of g. Atmospheric pressure is often

expressed in millimeters of mercury (mmHg), corresponding to the height difference h. The torr is equivalent to 1 mmHg, so standard atmospheric pressure is 760. torr, or 29.92 in of mercury (101.325 kPa).

An open-tube **manometer** measures the gauge pressure of a gas. It consists of a U-shaped tube partially filled with a liquid such as mercury (Figure 13.18). The closed end of the manometer is connected to a vessel containing the gas whose gauge pressure, p_g, is being measured, and the other end is open and thus experiences atmospheric pressure, p_0. Using equation 13.7 with $y_1 = 0$, $p_1 = p_0$, $y_2 = -h$, and $p_2 = p$, where p is the absolute pressure of the gas in the vessel, we obtain $p = p_0 + \rho g h$, the pressure-depth relationship derived earlier. The gauge pressure of the gas in the vessel is then

$$p_g = p - p_0 = \rho g h. \qquad \textbf{(13.9)}$$

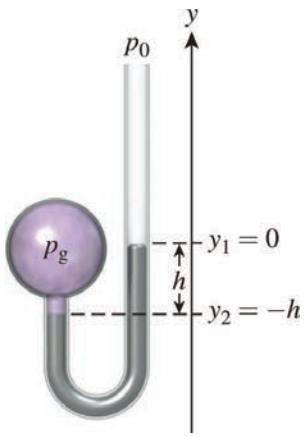

FIGURE 13.18 An open-tube manometer measures the gauge pressure of a gas.

Note that gauge pressure can be positive or negative. The gauge pressure of the air in an inflated automobile tire is positive. The gauge pressure at the end of a straw being used by a person drinking a milkshake is negative.

Barometric Altitude Relation for Gases

In deriving equation 13.8, we made use of the incompressibility of liquids. However, if the fluid is a gas, we cannot make this assumption. Let's start again with a thin layer of fluid in a column of the fluid. The pressure difference between the top and bottom surfaces is the negative of the weight of the thin layer of fluid divided by its area:

$$\Delta p = -\frac{F}{A} = -\frac{mg}{A} = -\frac{\rho V g}{A} = -\frac{\rho(\Delta h A)g}{A} = -\rho g \Delta h. \quad \textbf{(13.10)}$$

The negative sign reflects the fact that the pressure decreases with increasing altitude (h), since the weight of the fluid column above the layer will be reduced. So far, nothing is different from the derivation for the incompressible fluid. However, for compressible fluids, the density is proportional to the pressure:

$$\frac{\rho}{\rho_0} = \frac{p}{p_0}. \quad \textbf{(13.11)}$$

Strictly speaking, this relationship is true only for an ideal gas at constant temperature, as we will see in Chapter 19. However, if we combine equations 13.10 and 13.11, we obtain

$$\frac{\Delta p}{\Delta h} = -\frac{g\rho_0}{p_0} p.$$

Taking the limit as $\Delta h \to 0$, we have

$$\frac{dp}{dh} = -\frac{g\rho_0}{p_0} p.$$

This is an example of a differential equation. We need to find a function whose derivative is proportional to the function itself, which leads us to an exponential function:

$$p(h) = p_0 e^{-h\rho_0 g/p_0}. \quad \textbf{(13.12)}$$

It is easy to convince yourself that equation 13.12 is indeed a solution to the preceding differential equation by simply taking the derivative with respect to h. Equation 13.12 is sometimes called the **barometric pressure formula,**

and it relates the pressure to the altitude in gases. It applies only as long as the temperature does not change as a function of altitude and as long as the gravitational acceleration can be assumed to be constant. (We will consider the effect of temperature change when we discuss the ideal gas law in Chapter 19.)

We can obtain a formula for the air density, ρ, as a function of altitude by combining equations 13.11 and 13.12:

$$\rho(h) = \rho_0 e^{-h\rho_0 g/p_0}. \qquad \textbf{(13.13)}$$

Even though results obtained with this equation are only an approximation, they match actual atmospheric data fairly closely, as shown in Figure 13.19, where $\rho(h)$ was plotted with $g = 9.81\ \text{m/s}^2$, $p_0 = 1.01 \cdot 10^5$ Pa, the air pressure at sea level $(h = 0)$, and $\rho_0 = 1.229\ \text{kg/m}^3$, the air density at sea level. As you can see, the agreement is very close up to the top of the stratosphere, approximately 50 km above ground.

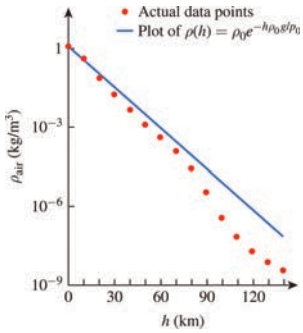

FIGURE 13.19
Comparison of the air density plotted from equation 13.13 (blue line) with actual data for the atmosphere (red dots).

EXAMPLE 13.3 Air Pressure on Mount Everest

As climbers approach the peak of Earth's highest mountain, Mount Everest, they usually have to wear breathing equipment. The reason for this is that the air pressure is very low, too low for climbers' lungs, which are usually accustomed to near sea-level conditions.

PROBLEM

What is the air pressure at the top of Mount Everest (Figure 13.20)?

FIGURE 13.20 Mount Everest is Earth's highest peak, at 8850 m (29,035 ft).

CORBIS

SOLUTION

This is a situation where we can use the barometric pressure formula (equation 13.12). We first note the constants: $p_0 = 1.01 \cdot 10^5$ Pa, the sea-level air pressure, and $\rho_0 = 1.229$ kg/m^3, the air density at sea level. Then we find the inverse of the constant part of the exponent in equation 13.12:

Page 407

$$\frac{p_0}{\rho_0 g} = \frac{1.01 \cdot 10^5 \text{ Pa}}{(1.229 \text{ kg/m}^3)\left(9.81 \text{ m/s}^2\right)} = 8377 \text{ m}.$$

We can then rewrite equation 13.12 as

$$p(h) = \rho_0 e^{-h/(8377 \text{ m})}.$$

The height of Mount Everest is 8850 m. Therefore, we obtain

$$p(8850 \text{ m}) = p_0 e^{-8850/8377} = 0.348\, p_0 = 35 \text{ kPa}.$$

The calculated air pressure at the top of Mount Everest is only 35% of the air pressure at sea level. (The actual pressure is slightly lower, mainly because of temperature effects.)

Concept Check 13.3

As you descend into a mine shaft below sea level, the air pressure

a) decreases linearly.

b) decreases exponentially.

c) increases linearly.

d) increases exponentially.

You do not have to travel to the top of Mount Everest to appreciate the change in air pressure with altitude. You have probably experienced your ears "popping" while driving in the mountains. This physiological effect of feeling pressure on the eardrums results because of a lag in your body's adjusting the internal pressure to the change in external pressure due to the rapid change in altitude.

Another demonstration of the change of air pressure with altitude is shown in Figure 13.21. A plastic water bottle made from a very soft plastic was emptied in Winter Park, Colorado, and sealed with air in it by tightly closing the lid. Winter Park is the highest incorporated town in the United States, at an altitude of over 3600 m. The bottle was then driven to the Denver airport, at an altitude of 1600 m, with the temperature inside the car kept constant. As you can see, the bottle crumpled, shrinking its volume significantly.

FIGURE 13.21 Demonstration of the change in air pressure with altitude. Left side: an air-filled, sealed plastic bottle at Winter Park, Colorado; right side: the same bottle in Denver, Colorado.

W. Bauer and G. D. Westfall

Concept Check 13.4

The air pressure inside the crushed bottle shown on the right in Figure 13.21

a) is significantly lower than the outside air pressure.

b) is significantly higher than the outside air pressure.

c) is approximately the same as the outside air pressure.

d) could be any of the above.

Pascal's Principle

If pressure is exerted on a part of an incompressible fluid, that pressure will be transmitted to all parts of the fluid without loss. This is **Pascal's Principle,** which can be stated as follows:

> *When a change in pressure occurs at any point in a confined fluid, an equal change in pressure occurs at every point in the fluid.*

Pascal's Principle is the basis for many modern hydraulic devices, such as automobile brakes, large earth-moving machines, and car lifts.

Pascal's Principle can be demonstrated by taking a cylinder partially filled with water, placing a piston on top of the column of water, and placing a weight on top of the piston (Figure 13.22). The air pressure and the weight exert a pressure, p_t, on top of the column of water. The pressure, p, at depth h is given by

$$p = p_t + \rho g h.$$

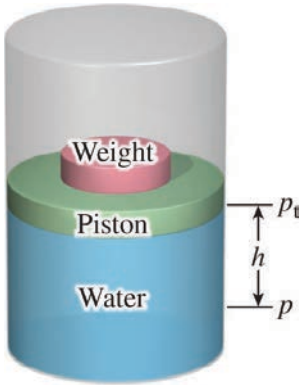

FIGURE 13.22
Cylinder partially filled with water, with a piston placed on top of the water and a weight placed on the piston.

Because water can be considered incompressible, if a second weight is added on top of the piston, the change in pressure, Δp, at depth h is due solely to the change in the pressure, Δp_t, on top of the water. The density of the water does not change and the depth does not change, so we can write

$$\Delta p = \Delta p_t.$$

This result does not depend on h, so it must hold for all positions in the liquid.

Now consider two connected pistons in cylinders filled with oil, as shown in Figure 13.23. One piston has area A_{in} and the other piston has area A_{out}, with $A_{in} < A_{out}$. A force, F_{in}, is exerted on the first piston, producing a change in pressure in the oil. This change in pressure is transmitted to all points in the oil, including points adjacent to the second piston. We can write

$$\Delta p = \frac{F_{in}}{A_{in}} = \frac{F_{out}}{A_{out}},$$

or

$$F_{out} = F_{in}\frac{A_{out}}{A_{in}}. \qquad \textbf{(13.14)}$$

Because A_{out} is larger than A_{in}, F_{out} is larger than F_{in}. Thus, the force applied to the first piston is magnified. This phenomenon is the basis of hydraulic devices that produce large output forces with small input forces.

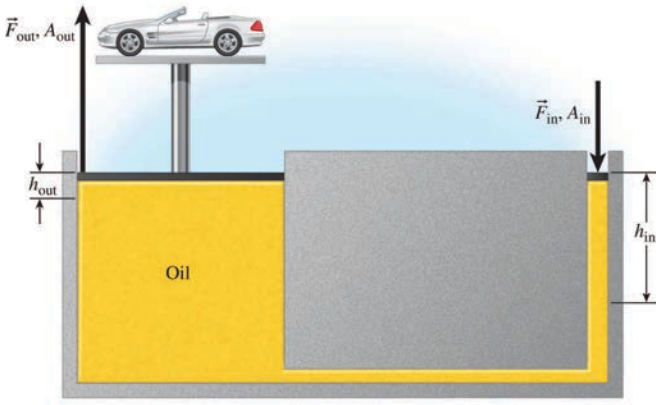

FIGURE 13.23 Application of Pascal's Principle in a hydraulic lift. (The scale of the lift relative to the car is greatly out of proportion in order to show the essential details clearly.)

The amount of work done on the first piston is the same as the amount of work done by the second piston. To calculate the work done, we need to calculate the distance over which the forces act. For both pistons, the volume, V, of incompressible oil that is moved is the same:

$$V = h_{in}A_{in} = h_{out}A_{out},$$

where h_{in} is the distance the first piston moves and h_{out} is the distance the second piston moves. We can see that

Concept Check 13.5

A car weighing 10,000. N is supported by a hydraulic car lift, as illustrated in Figure 13.23. The large piston supporting the car has a diameter of 25.4 cm. The small piston has a diameter of 2.54 cm. How much force must be exerted on the small piston to support the car?

a) 1.00 N

b) 10.0 N

c) 100. N

d) 14.1 N

e) 141 N

$$h_{\text{out}} = h_{\text{in}} \frac{A_{\text{in}}}{A_{\text{out}}}, \tag{13.15}$$

which means that the second piston moves a smaller distance than the first piston because $A_{\text{in}} < A_{\text{out}}$. We can find the work done by using the fact that work is force times distance and using equations 13.14 and 13.15:

$$W = F_{\text{in}} h_{\text{in}} = \left(F_{\text{out}} \frac{A_{\text{in}}}{A_{\text{out}}} \right) \left(h_{\text{out}} \frac{A_{\text{out}}}{A_{\text{in}}} \right) = F_{\text{out}} h_{\text{out}}.$$

Thus, this hydraulic device transmits a larger force over a smaller distance. However, no additional work is done.

13.5 Archimedes' principle

Archimedes (287–212 BC) of Syracuse, Sicily, was one of the greatest mathematicians of all time. The king, Hiero of Syracuse, ordered a new crown made and gave the goldsmith the exact amount of gold needed to create the crown. When the crown was finished, it had the correct weight, but Hiero suspected that the goldsmith had used some silver in the crown to replace the more valuable gold. Hiero could not prove this and went to Archimedes for help. According to legend, the answer occurred to Archimedes as he was about to take a bath and noticed the water level rising and his apparent weight diminishing when he got into the bathtub. He then ran naked through the streets of Syracuse to the palace, shouting "Eureka!" (Greek for "I have found it!"). Using his discovery, he was able to demonstrate the silver-for-gold switch and thus prove the theft committed by the goldsmith. Later in this section, we'll examine Archimedes' method for solving this problem, after considering buoyant force and fluid displacement.

Buoyant Force

Figure 13.14 shows a cube of water within a larger volume of water. The weight of the cube of water is supported by the force resulting from the pressure difference between the top and bottom surfaces of the cube, as given by equation 13.6, which we can rewrite as

$$F_2 - F_1 = mg = F_{\mathrm{B}}, \tag{13.16}$$

where F_B is defined as the **buoyant force** acting on the cube of water. For the case of the cube of water, the buoyant force is equal to the weight of the water. In general, the buoyant force acting on a submerged object is given by the weight of the fluid displaced,

$$F_{\mathrm{B}} = m_{\mathrm{f}} g.$$

Now suppose the cube of water is replaced with a cube of steel (Figure 13.24). Because the steel cube has the same volume and is at the same depth as the cube of water, the buoyant force remains the same. However, the steel cube weighs more than the cube of water, so a net y-component of force acts on the steel cube, given by

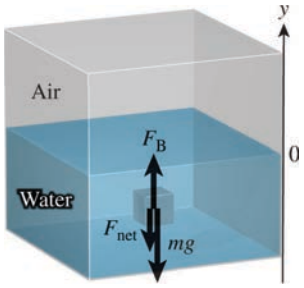

FIGURE 13.24 The weight of a steel cube submerged in water is larger than the buoyant force acting on the cube.

$$F_{\mathrm{net},y} = F_{\mathrm{B}} - m_{\mathrm{steel}} g < 0.$$

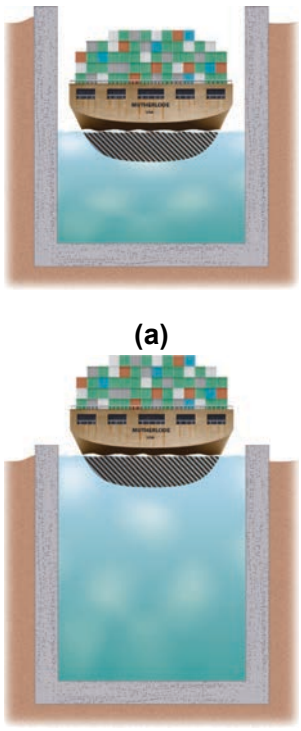
This net downward force causes the steel cube to sink.

If the cube of water is replaced by a cube of wood, the weight of the cube of wood is less than that of the cube of water, so the net force will be upward. The wooden cube will rise toward the surface. If an object that is less dense than

water is placed in water, it will float. An object of mass m_{object} will sink in water until the weight of the displaced water equals the weight of the object:

$$F_{\text{B}} = m_{\text{f}}g = m_{\text{object}}g.$$

A floating body displaces its own weight of fluid. This statement is true, independent of the amount of fluid present. To make this clearer, Figure 13.25 shows a ship in a lock. Part (a) shows the ship in the low position, and part (b) in the high position. In both positions, the ship floats, with the same fraction of the ship below the water level. What matters for the buoyant force is not the total amount of the water in the lock (light blue in the figure), but the amount of water displaced by the underwater portion of the ship (hatched blue and brown in the figure). Clearly, in Figure 13.25a, there is much less water left in the lock than the volume that has been displaced by the ship. The only thing that matters is the weight of the water that *would be where the ship is,* not the weight of the water still in the lock. (In fact, with a container of the right shape, even a single gallon of water could be "enough to float a battleship.")



(a)

(b)

FIGURE 13.25 A ship in a lock: (a) low position; (b) high position.

If an object that has a higher density than water is placed under water, it will experience an upward buoyant force that is less than its weight. Its apparent weight is then given by

$$\text{Actual weight} - \text{buoyant force} = \text{apparent weight}. \quad \textbf{(13.17)}$$

EXAMPLE 13.4 Floating Iceberg

Icebergs, such as the one shown in Figure 13.26a, pose grave dangers for ocean-going ships. Many ships, the *Titanic* most famously, have sunk after collisions with icebergs. The trouble is that a large fraction of an iceberg's volume is hidden below the waterline and thus practically invisible to sailors, as illustrated in Figure 13.26b.

FIGURE 13.26 (a) An iceberg floating in the ocean. (b) Illustration showing the fraction of the volume of the iceberg above and below the waterline.

NOAA

PROBLEM

What fraction of the volume of an iceberg floating in seawater is visible above the surface?

SOLUTION

Let V_t be the total volume of the iceberg and V_s be the volume of the iceberg that is submerged. The fraction, *f,* above water is then

$$f = \frac{V_t - V_s}{V_t} = 1 - \frac{V_s}{V_t}.$$

Because the iceberg is floating, the submerged volume must displace a volume of seawater that has the same weight as the entire iceberg. The mass of the iceberg, m_t, can be calculated from the volume of the iceberg and the density of ice, $\rho_{ice} = 0.917\ \text{g/cm}^3$. The mass of the displaced seawater can be calculated from the submerged volume and the known density of seawater, $\rho_{seawater} = 1.024\ \text{g/cm}^3$. We equate the two weights:

$$\rho_{ice} V_t g = \rho_{seawater} V_s g,$$

or

$$\rho_{\text{ice}} V_{\text{t}} = \rho_{\text{seawater}} V_{\text{s}}.$$

We can rearrange this equation to get

$$\frac{V_{\text{s}}}{V_{\text{t}}} = \frac{\rho_{\text{ice}}}{\rho_{\text{seawater}}}.$$

We can now find the fraction above water:

$$f = 1 - \frac{V_{\text{s}}}{V_{\text{t}}} = 1 - \frac{\rho_{\text{ice}}}{\rho_{\text{seawater}}} = 1 - \frac{0.917 \text{ g/cm}^3}{1.024 \text{ g/cm}^3} = 0.104,$$

or about 10%. Figure 13.26b shows an iceberg with approximately 10% of its volume above the waterline.

An interesting experiment on buoyancy can be performed as follows. You pour water (with red food coloring) into a container (Figure 13.27a) and put a swimmer into it (Figure 13.27b). The swimmer is 90% submerged, so its average density is 90% of that of water, like the iceberg in Example 13.4. Next, you pour paint thinner on top of the water. Paint thinner does not mix with water and has a density equal to 80% of that of water. Thus, it rests on top of the water. If you put the swimmer into a container of paint thinner, the swimmer would sink to the bottom. So, what happens when you pour the paint thinner on top of the water with the swimmer in it? Will the swimmer rise, stay at the same level, or sink?

FIGURE 13.27 Buoyancy experiment with two liquids: (a) water with red dye; (b) a swimmer placed in the water; (c) paint thinner added above the water.

W. Bauer and G. D. Westfall

The answer is shown in Figure 13.27c: The swimmer rises. Why? In the two liquids, two buoyant forces are present—one from the fraction of the swimmer's volume submerged in water, and the other from the fraction of the swimmer's volume submerged in the paint thinner. Therefore, to generate the same buoyant force, less of the volume of the swimmer needs to be submerged in the water when paint thinner is also present than when air and no paint thinner lies on top of the water.

EXAMPLE 13.5 A Hot-Air Balloon

A typical hot-air balloon has a volume of 2200. m^3. The density of air at a temperature of 20. $^\circ\mathrm{C}$ is 1.205 $\mathrm{kg/m}^3$. The density of the hot air inside the balloon at a temperature of 100. $^\circ\mathrm{C}$ is 0.946 $\mathrm{kg/m}^3$.

PROBLEM

How much weight can the hot-air balloon shown in Figure 13.28 lift (counting the balloon itself)?

FIGURE 13.28
Hot-air balloon in flight.

Benjamin Simeneta/Getty Images

SOLUTION

The weight of the air at 20 $^\circ\mathrm{C}$ that the balloon displaces is equal to the buoyant force:

$$F_\mathrm{B} = \rho_{20} V g.$$

The weight of the hot air inside the balloon is

$$W_\mathrm{baloon} = \rho_{100} V g.$$

The weight that can be lifted is

$$\begin{aligned} W &= F_\mathrm{B} - W_\mathrm{balloon} = \rho_{20} V g - \rho_{100} V g \\ &= V g(\rho_{20} - \rho_{100}) = \left(2200\ \mathrm{m}^3\right)\left(9.81\ \mathrm{m/s}^2\right)\left(1.205\ \mathrm{kg/m}^3 - 0.94\right. \\ &= 5590\ \mathrm{N}. \end{aligned}$$

Note that this weight must include the balloon envelope, the basket, and the fuel, as well as any payload such as the pilot and passengers.

Determination of Density

Let's return to Archimedes' method of figuring out if the king's new crown was pure gold or a mixture of silver and gold. Since the density of gold is 19.3 g/cm^3 and the density of silver is only 10.5 g/cm^3, Archimedes needed to measure the density of the crown to find out what fraction of it was gold and what fraction was silver. However, how could he measure the density? He needed to submerge the crown in water and determine its volume from the rise in the water level. Weighing the crown gave him the mass, and dividing the mass by the volume yielded the density, the answer the king wanted.

Self-Test Opportunity 13.3

Suppose the balloon in Example 13.5 were filled with helium instead of hot air. How much weight could the helium-filled balloon lift? The density of helium is 0.164 kg/m^3.

EXAMPLE 13.6 Finding the Density of an Object

The method shown in Figure 13.29 can be used to determine the density of an object just by weighing it, without the need to measure water levels. This method is usually more precise and thus is preferred. We first weigh a beaker containing water (with green food coloring added) whose density is assumed to be 1000 kg/m^3, as shown in part (a). The mass of the beaker and water is determined to be $m_0 = 0.437$ kg. In part (b), we submerge a metal ball, suspended by a string, in the water, being careful not to let the ball touch the bottom of the beaker. The new total apparent mass of this arrangement is determined in part (c) as $m_1 = 0.458$ kg. Finally, in part (d), we let the ball rest on the bottom of the beaker, without pulling on the string. Now the mass is determined to be $m_2 = 0.596$ kg.

(b)

(c)

(d)

FIGURE 13.29 Method for determining the density of a metal object.

W. Bauer and G. D. Westfall

PROBLEM

What is the density of the metal ball?

SOLUTION

Figure 13.30 shows free-body diagrams for the different parts of Figure 13.29. The leftmost diagram shows the ball suspended from the string in static equilibrium, with its weight $-m_{\mathrm{b}}g\hat{y}$, balanced by the string tension,

$\vec{T}$. The diagram second from the left in Figure 13.30 corresponds to Figure 13.29a and shows the only forces acting on the water-filled container, which are its weight, $-m_0 g\hat{y}$, and the normal force, $m_0 g\hat{y}$. The value of m_0 was determined as the result of the first measurement. The diagram third from the left in Figure 13.30 corresponds to parts (b) and (c) in Figure 13.29 and shows the free-body diagram of the submerged ball as well as the free-body diagram of the container; it illustrates the effect of the buoyant force, $\vec{F}_{\mathrm{B}}$, on the ball and on the liquid-filled container. Note that the ball experiences an upward buoyant force and thus the container must experience a force of equal magnitude and opposite direction (downward), or $-\vec{F}_{\mathrm{B}}$, according to Newton's Third Law. The normal force required to keep the container in equilibrium in this situation is $m_1 g\hat{y}$. The rightmost free-body diagram in Figure 13.30 corresponds to part (d) of Figure 13.29 and shows the normal force as $m_2 g\hat{y}$.

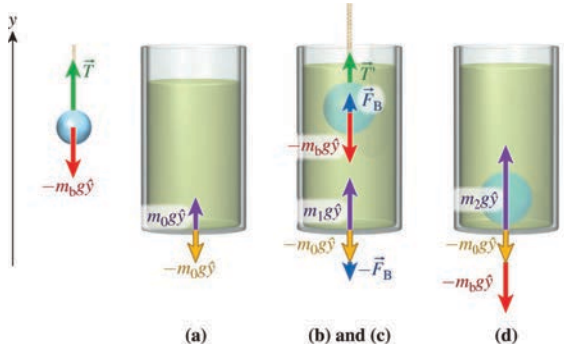

FIGURE 13.30 Free-body diagrams for the different parts of the experiment.

The combined mass of water and beaker, m_0 was determined in part (a) of the method illustrated in Figure 13.30. In part (c), we measured in addition the mass of the water displaced by the (as yet unknown) volume V of the metal ball. The mass of the displaced water is $m_{\mathrm{w}} = \rho_{\mathrm{w}} \mathrm{V}_{\mathrm{b}}$, and the total mass measured in part (c) is

$$m_1 = m_0 + \rho_{\mathrm{w}} \mathrm{V}_{\mathrm{b}}. \qquad \text{(i)}$$

Finally, the mass measured in part (d) is the combined mass of the ball, the beaker, and the water. For the mass of the ball, we can again use the product of the density and the volume:

$$m_2 = m_0 + m_{\mathrm{b}} = m_0 + \rho_{\mathrm{b}} \mathrm{V}_{\mathrm{b}}. \qquad \text{(ii)}$$

Combining equations (i) and (ii), we have

$$\frac{m_2 - m_0}{m_1 - m_0} = \frac{\rho_\mathrm{b} \mathrm{V}_\mathrm{b}}{\rho_\mathrm{w} \mathrm{V}_\mathrm{b}} = \frac{\rho_\mathrm{b}}{\rho_\mathrm{w}}.$$

As you can see, the volume of the ball has canceled out, and we can obtain the density of the ball from the known density of water and our three measurements, m_0, m_1, and m_2:

$$\rho_\mathrm{b} = \frac{m_2 - m_0}{m_1 - m_0}\rho_\mathrm{w} = \frac{0.596 - 0.437}{0.458 - 0.437}\left(1000 \text{ kg/m}^3\right) = 7570 \text{ kg/m}^3.$$

Self-Test Opportunity 13.4

What is the mass of the metal ball in Example 13.6?

Concept Check 13.6

Suppose we use the same setup as in Example 13.6 and a ball of the same size, but half as dense: $\rho_\mathrm{b} = 3785 \mathrm{kg/m}^3$. The measurement of m_1 (with the ball held by a string so that it is under water, but not touching the bottom of the beaker) will yield

a) a lower value.

b) the same value.

c) a higher value.

The mass measurement of m_2 (with the ball resting at the bottom of the beaker) will yield

a) a lower value.

b) the same value.

c) a higher value.

SOLVED PROBLEM 13.3 Finding the Density of an Unknown Liquid

PROBLEM

A solid aluminum sphere $\left(\text{density } = 2700.\ \text{kg/m}^3\right)$ is suspended in air from a scale (Figure 13.31a). The scale reads 13.06 N. The sphere is then submerged in a liquid with unknown density (Figure 13.31b). The scale then reads 8.706 N. What is the density of the liquid?

FIGURE 13.31 (a) An aluminum sphere suspended in air. (b) The aluminum sphere submerged in an unknown liquid.

SOLUTION

THINK

From Newton's Third Law, the buoyant force exerted by the unknown liquid on the aluminum sphere is the difference between the scale reading when the sphere is suspended in air and the scale reading when the sphere is submerged in the liquid.

SKETCH

Free-body diagrams of the sphere in each situation are shown in Figure 13.32.

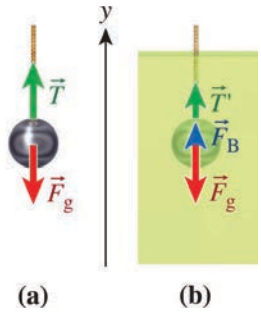

FIGURE 13.32 Free-body diagrams for the sphere (a) suspended in air and (b) submerged in the liquid.

RESEARCH

The buoyant force, F_B, exerted by the unknown liquid is

$$F_B = m_1 g, \tag{i}$$

where the mass of the displaced liquid, m_1 can be expressed in terms of the volume of the sphere, V, and the density of the liquid, ρ_1:

$$m_1 = \rho_1 V. \tag{ii}$$

We can obtain the buoyant force exerted by the unknown liquid by subtracting the measured weight of the sphere when it is submerged in the unknown liquid, F_{sub}, from the measured weight when it is suspended in air, F_{air}:

$$F_B = F_{air} - F_{sub}. \tag{iii}$$

The mass of the sphere can be obtained from its weight in air:

$$F_{air} = m_s g. \tag{iv}$$

Using the known density of aluminum, ρ_{A1}, we can express the volume of the aluminum sphere as

$$\mathrm{V} = \frac{m_\mathrm{s}}{\rho_\mathrm{A1}}. \qquad \text{(v)}$$

SIMPLIFY

We can combine equations (i), (ii), and (iii) to get

$$F_\mathrm{B} = m_1 g = \rho_1 V g = F_\mathrm{air} - F_\mathrm{sub}. \qquad \text{(vi)}$$

We can use equations (iv) and (v) to get an expression for the volume of the sphere in terms of known quantities:

$$V = \frac{m_\mathrm{s}}{\rho_\mathrm{A1}} = \frac{\left(\frac{F_\mathrm{air}}{g}\right)}{\rho_\mathrm{A1}} = \frac{F_\mathrm{air}}{\rho_\mathrm{A1} g}.$$

Substituting this expression for V into equation (vi) gives us

$$\rho_1 V g = \rho_1 \left(\frac{F_\mathrm{air}}{\rho_\mathrm{A1} g}\right) g = F_\mathrm{air} \frac{\rho_1}{\rho_\mathrm{A1}} = F_\mathrm{air} - F_\mathrm{sub}.$$

Now, we solve for the density of the unknown liquid:

$$\rho_1 = \rho_\mathrm{A1} \frac{(F_\mathrm{air} - F_\mathrm{sub})}{F_\mathrm{air}}.$$

CALCULATE

Putting in the numerical values gives us the density of the unknown liquid:

$$\rho_1 = \rho_\mathrm{A1} \frac{(F_\mathrm{air} - F_\mathrm{sub})}{F_\mathrm{air}} = \left(2700.\ \mathrm{kg/m^3}\right) \frac{13.06\ \mathrm{N} - 8.706\ \mathrm{N}}{13.06\ \mathrm{N}} = 900.$$

ROUND

We report our result to four significant figures:

$$\rho_1 = 900.1\ \mathrm{kg/m^3}.$$

DOUBLE-CHECK

The calculated density of the unknown liquid is 90% of the density of water. Many liquids have such densities, so our answer seems reasonable.

13.6 Ideal Fluid Motion

We have been examining the behavior of fluids at rest but now turn to fluids in motion. The motion of real-life fluids is complicated and difficult to describe. Numerical techniques and computers are often required to calculate the quantities related to fluid motion. In this section, we consider ideal fluids that can be treated more simply and still yield important and relevant results. To be considered ideal, a fluid must exhibit flow that is laminar, incompressible, nonviscous, and irrotational.

Laminar flow means that the velocity of the moving fluid relative to a fixed point in space does not change with time. A gently flowing river displays laminar flow (Figure 13.33a). Water in a waterfall exhibits nonlaminar flow, or **turbulent flow** (Figure 13.33c). Rising smoke exemplifies a transition from laminar to turbulent flow (Figure 13.33b). The warm smoke initially displays laminar flow as it rises. As the smoke continues to rise, its speed increases until turbulent flow sets in.

FIGURE 13.33 (a) Laminar flow of the Firehole River at Yellowstone; (b) transition from laminar to turbulent flow in rising smoke; (c) turbulent flow at the Upper Falls on the Yellowstone River.

a, c: W. Bauer and G. D. Westfall; **b:** Don Farrall/Getty Images

Incompressible flow means that the density of the liquid does not change as the liquid flows. A **nonviscous fluid** flows completely freely. Some liquids that do not flow freely are pancake syrup and lava. The viscosity of a fluid has an effect analogous to friction. An object moving in a nonviscous liquid experiences no friction-like force, but the same object moving in a viscous liquid is subject to a drag force that is due to the viscosity and is similar to friction. A flowing viscous fluid loses kinetic energy of motion to thermal energy. We assume that ideal fluids do not lose energy as they flow.

Irrotational flow means that no part of the fluid rotates about its own center of mass. Rotational motion of a small part of the fluid would mean that

the rotating part had rotational energy, which is assumed not to occur in ideal fluids.

Laminar flow can be described in terms of streamlines (Figure 13.34). A streamline represents the path that a small element of the fluid takes over time. The velocity, $\vec{v}$, of the small element is always tangent to the streamline. Note that streamlines never cross; if they did, the velocity of flow at the crossing point would have two values.

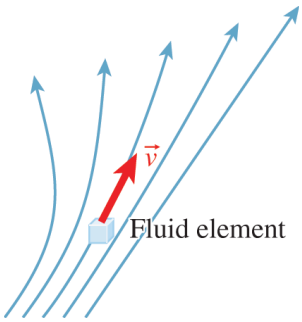

FIGURE 13.34
Streamlines of a fluid in laminar flow.

Bernoulli's Equation

What provides the lift that allows an airplane to fly through the air? To understand this phenomenon, you can do a simple demonstration with two empty soft-drink cans and five drinking straws. Place each empty can on two straws, with a gap of approximately 1 cm between them, as shown in Figure 13.35. In this arrangement, the cans are able to make lateral movements relatively easily. Now, using the fifth straw, blow air through the gap between the cans. What happens? (This question will be answered later in the section.)

FIGURE 13.35
Blowing air through the gap between two empty soft-drink cans.

W. Bauer and G. D. Westfall

To begin our studies of fluid motion, let us first introduce the equation of continuity. Consider an ideal fluid flowing with speed v in a container or pipe with cross-sectional area A (Figure 13.36). Then ΔV is the volume of fluid that flows through the pipe during time Δt and is given by

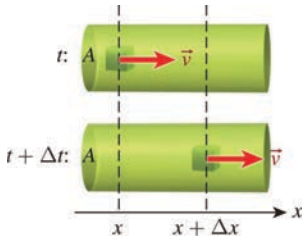

FIGURE 13.36
Ideal fluid flowing through a pipe with a constant cross-sectional area.

$$\Delta V = A\Delta x = Av\Delta t.$$

We can write the volume of fluid passing a given point in the pipe per unit time as

$$\frac{\Delta V}{\Delta t} = Av.$$

Now consider an ideal fluid flowing in a pipe that has a cross-sectional area that changes (Figure 13.37). The fluid is initially flowing with speed v_1 through a part of the pipe with cross-sectional area A_1. Downstream, the fluid flows with speed v_2 in a part of the pipe with cross-sectional area A_2. The volume of ideal fluid that enters this section of the pipe per unit time must equal the volume of ideal fluid exiting the pipe per unit time because the fluid is incompressible and the pipe has no leaks. We can express the volume flowing in the first part of the pipe per unit time as

FIGURE 13.37
Ideal fluid flowing through a pipe with a changing cross-sectional area.

$$\frac{\Delta V}{\Delta t} = A_1 v_1$$

Concept Check 13.7

Another demonstration is done by holding two sheets of paper parallel to each other at a separation of approximately an inch and blowing air between them. What do you expect the motion of the sheets of paper will be?

a) They will move away from each other.

b) They will remain at approximately the same separation.

c) They will move toward each other.

and the volume flowing in the second part of the pipe per unit time as

$$\frac{\Delta V}{\Delta t} = A_2 v_2.$$

The volume of fluid passing any point in the pipe per unit time must be the same in all parts of the pipe, or else fluid would somehow be created or destroyed. Thus, we have

$$A_1 v_1 = A_2 v_2. \tag{13.18}$$

This equation is called the **equation of continuity.**

We can express equation 13.18 as a constant volume flow rate, R_{V}:

$$R_{\mathrm{V}} = Av.$$

Assuming an ideal fluid whose density does not change, we can also express a constant mass flow rate, R_{m}:

$$R_{\mathrm{m}} = \rho A v.$$

The SI unit for mass flow rate is kilograms per second $(\mathrm{kg/s})$.

Let's now consider what happens to the pressure in an ideal fluid flowing through a pipe at a steady rate (Figure 13.38). We start by applying the work-energy theorem to the ideal fluid flowing between the lower part and the upper part of the pipe. In the lower left part of the pipe, the flowing fluid of constant density, ρ, is characterized by pressure p_1, speed v_1, and elevation y_1. The same fluid flows through the transition region and into the upper right part of the pipe. Here the fluid is characterized by pressure p_2, speed v_2, and elevation y_2. We will show that the relationship between the pressures and velocities in this situation is given by

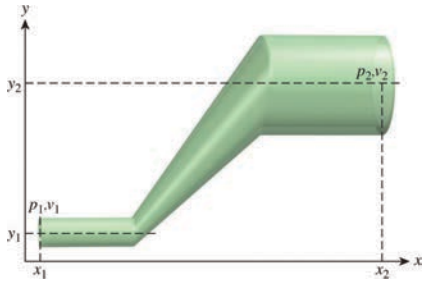

FIGURE 13.38 Ideal fluid flowing through a pipe with changing cross-sectional area and elevation.

$$p_1 + \rho g y_1 + \tfrac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \tfrac{1}{2}\rho v_2^2. \qquad \textbf{(13.19)}$$

Another way of stating this relationship is

$$p + \rho g y + \tfrac{1}{2}\rho v^2 = \text{constant}. \qquad \textbf{(13.20)}$$

This equation is **Bernoulli's Equation.** If there is no flow, $v = 0$ and equation 13.20 is equivalent to equation 13.8.

One major consequence of Bernoulli's Equation becomes evident if $y = 0$, which means that, at constant elevation,

$$p + \tfrac{1}{2}\rho v^2 = \text{constant}. \qquad \textbf{(13.21)}$$

From equation 13.21, we can see that if the velocity of a moving fluid is increased, the pressure must decrease. The decrease of the pressure transverse to the fluid flow has many practical applications, including the measurement of the flow rate of a fluid and the creation of a partial vacuum.

Derivation 13.1 develops Bernoulli's Equation mathematically. The only two conditions that enter into this derivation are the law of conservation of energy and the equation of continuity, which simply restates the basic fact that the number of atoms in the ideal fluid is conserved.

DERIVATION 13.1 Bernoulli's Equation

The work-energy theorem tells us that the net work done on the system, W, is equal to the change in kinetic energy, ΔK, of the fluid flowing between the initial and final cross sections of the pipe in Figure 13.38:

$$W = \Delta K. \tag{i}$$

The change in kinetic energy is given by

$$\Delta K = \tfrac{1}{2}\Delta m v_2^2 - \tfrac{1}{2}\Delta m v_1^2, \tag{ii}$$

where Δm is the amount of mass entering the lower part of the pipe and exiting the upper part of the pipe in time Δt. The flow of mass per unit time is the density of the fluid times the change in volume per unit time:

$$\frac{\Delta m}{\Delta t} = \rho \frac{\Delta V}{\Delta t}.$$

Thus, we can rewrite equation (ii) as

$$\Delta K = \tfrac{1}{2}\rho \Delta V \left(v_2^2 - v_1^2\right).$$

The work done by gravity on the flowing fluid is given by

$$W_{\text{g}} = -\Delta m g (y_2 - y_1), \tag{iii}$$

where the negative sign arises because negative work is being done by gravity on the fluid when $y_2 > y_1$. We can also rewrite equation (iii) in terms of the volume flow ΔV and the density of the fluid:

$$W_{\text{g}} = -\rho \Delta V g (y_2 - y_1).$$

The work done by a force, F, acting over a distance, Δx, is given by $W = F\Delta x$, which in this case we can express as

$$W = F\Delta x = (pA)\Delta x = p\Delta V,$$

because the force arises from the pressure in the fluid. We can then express the work done on the fluid by the pressure forcing the fluid to flow into the

pipe as $p_1 \Delta V$ and the work done on the exiting fluid as $-p_2 \Delta V$, giving the work done as a result of pressure,

$$W_\mathrm{p} = (p_1 - p_2)\Delta V.$$

$p_1 \Delta V$ is positive because it arises from fluid to the left of flow exerting a force on fluid entering the pipe. $p_2 \Delta V$ is negative because it arises from fluid to the right of flow exerting a force on fluid exiting the pipe. Using equation (i) and $W = W_\mathrm{p} + W_\mathrm{g}$, we get

$$(p_1 - p_2)\Delta V - \rho \Delta V g(y_2 - y_1) = \tfrac{1}{2}\rho \Delta V \left(v_2^2 - v_1^2\right),$$

which we can simplify to

$$p_1 + \rho g y_1 + \tfrac{1}{2}\rho v_1^2 = p_2 + \rho g y_2 + \tfrac{1}{2}\rho v_2^2.$$

This is Bernoulli's Equation.

EXAMPLE 13.7 Betz Limit

PROBLEM

In Chapter 5, we found that the power contained in wind moving with a speed v through an area A is $P = \frac{1}{2}Av^3\rho$, where ρ is the density of air. Now that we know about ideal fluids and energy conservation, we can derive a limit on the fraction of this power that a turbine can actually extract from the wind.

SOLUTION

Obviously, the wind speed has to change during the interaction with the rotor; otherwise, the kinetic energy of the wind would not change, and energy conservation would not allow the turbine to extract energy from the wind. If v_1 is the speed of the wind before it hits the rotor, v_2 is the speed after it passes through the rotor, and v is the speed at the rotor (see Figure 13.39), then v can be assumed to be the average of v_1 and v_2 : $v = \frac{1}{2}(v_1 + v_2)$.

FIGURE 13.39
Wind speeds in front of, at, and behind a rotor.

W. Bauer and G. D. Westfall

The average power is the kinetic energy that the wind loses from before hitting the rotor to after doing so:

$$P = \frac{\Delta K}{\Delta t} = \frac{1}{2}\frac{\Delta m}{\Delta t}\left(v_1^2 - v_2^2\right).$$

We already calculated the mass flow rate for an incompressible fluid:

$$R_{\mathrm{m}} \equiv \frac{\Delta m}{\Delta t} = \rho A v.$$

Substituting for $\Delta m/\Delta t$ in our expression for the average power and then substituting the expression we obtained above for v yields

$$P = \tfrac{1}{2}\frac{\Delta m}{\Delta t}\left(v_1^2 - v_2^2\right) = \tfrac{1}{2}\rho A v\left(v_1^2 - v_2^2\right) = \tfrac{1}{2}\rho A \tfrac{1}{2}(v_1 + v_2)\left(v_1^2 - v_2^2\right)$$

Rearranging this and using a bit of algebra gives

$$P = \tfrac{1}{2}\rho A v_1^3 \tfrac{1}{2}\left(1 + (v_2/v_1) - (v_2/v_1)^2 - (v_2/v_1)^3\right).$$

This is the result that we found in Chapter 5 but with an extra factor, which is the sum of various powers of the ratio $\chi \equiv v_2/v_1$ of the wind speeds behind and in front of the rotor:

$$P = \tfrac{1}{2}\rho A v_1^3 f(\chi), \text{ with } f(\chi) = \tfrac{1}{2}\left(1 + \chi - \chi^2 - \chi^3\right).$$

To find the maximum extracted power, we have to differentiate the expression for the average power with respect to $\chi \equiv v_2/v_1$:

$$\frac{dP}{d\chi} = \tfrac{1}{2}\rho A v_1^3 \frac{df(\chi)}{d\chi}.$$

Taking the derivative, we obtain

$$\frac{df(\chi)}{d\chi} = \tfrac{1}{2}\left(1 - 2\chi - 3\chi^2\right) = 0 \Rightarrow \chi = \tfrac{1}{3} \text{ or } \chi = -1.$$

Since the ratio of the wind speeds has to be between 0 and 1, only $\chi_{\mathrm{m}} = \frac{1}{3}$ is a solution. By taking the second derivative, you can convince yourself that this value is indeed the maximum. Inserting it into *f*, we find $f(\chi_{\mathrm{m}}) = 16/27 \approx 0.593$.

What does this result mean? In order to extract the maximum fraction of the power contained in wind, the rotor of a turbine has to be designed so that the wind speed behind it is $\frac{1}{3}$ of the wind speed in front of it, and in this optimum case, approximately 59.3% of the total wind power can be extracted (see Figure 13.40). This limit is known as the *Betz limit*, after Albert Betz, who derived it first, in 1919.

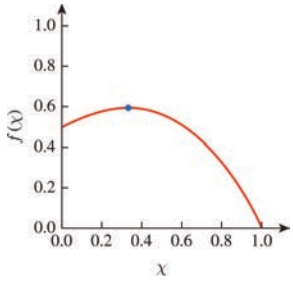

FIGURE 13.40
Dependence of the fraction of power that can be extracted from wind on the ratio of the wind speeds behind and in front of a rotor. The blue dot marks the maximum.

Applications of Bernoulli's Equation

Now that we have derived Bernoulli's Equation, we can return to the demonstration of Figure 13.35. If you performed this demonstration, you found that the two soft-drink cans moved closer to each other. This is the opposite of what most people expect, which is that blowing air in the gap will force the cans apart. Bernoulli's Equation explains this surprising result. Since $p + \frac{1}{2}\rho v^2 = \text{constant}$, the large speed with which the air is moving between the cans causes the pressure to decrease. Thus, the air pressure between the cans is smaller than the air pressure on other parts of the cans, causing the cans to be pushed toward each other. This is the *Bernoulli effect*. Another way to show the same effect is to hold two sheets of paper parallel to each other about an inch apart and then blow air between them: The sheets are pushed together.

Truck drivers know about this effect. When two 18-wheelers with the typical rectangular box trailers drive in lanes next to each other at high speed, the drivers have to pay attention not to come too close to each other, because the Bernoulli effect can then push the trailers toward each other.

Race car designers also make use of the Bernoulli effect. The biggest limitation on the acceleration of a race car is the maximum friction force between the tires and the road. This friction force, in turn, is proportional to the normal force. The normal force can be increased by increasing the car's mass, but this defeats the purpose, because a larger mass means a smaller acceleration, according to Newton's Second Law. A much more efficient way to increase the normal force is to develop a large pressure difference between the upper and lower surfaces of the car. According to Bernoulli's Equation, this can be accomplished by causing the air to move faster across the bottom of the car than across the top. (Another way to accomplish this would be to use a wing to deflect the air up and thus create a downward force. However, wings have been ruled out in Formula 1 racing.)

Let's reconsider the question of what causes an airplane to fly. Figure 13.41 shows the forces acting on an airplane flying with constant velocity and at constant altitude. The thrust, $\overrightarrow{F}_{\text{t}}$, is generated by the jet engines taking in air from the front and expelling it out the back. This force is directed toward the front of the plane. The drag force, $\overrightarrow{F}_{\text{d}}$, due to air resistance (discussed in Chapter 4) is directed toward the rear of the plane. At constant velocity, these two forces cancel: $\overrightarrow{F}_{\text{t}} = \overrightarrow{F}_{\text{d}}$. The forces acting in the vertical direction are the weight, $\overrightarrow{F}_{\text{g}}$, and the lift, $\overrightarrow{F}_{\text{l}}$, which is provided almost exclusively by the wings. If the plane flies at constant altitude, these two forces cancel as well: $\overrightarrow{F}_{\text{l}} = \overrightarrow{F}_{\text{g}}$.

Since a fully loaded and fueled Boeing 747 typically has a mass of 350 metric tons, its weight is 3.4 MN. Thus, the lift provided by the wings to keep the airplane flying must be very large. By comparison, the maximum thrust produced by all four engines on a 747 is 0.9 MN.

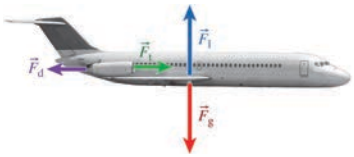

FIGURE 13.41 Forces acting on an airplane in flight.

© W. Bauer and G. D. Westfall

The most commonly held notion of what generates the lift that allows a plane to stay airborne is shown in Figure 13.42a: The wing moves through the air and forces the air streamlines that move above it onto a longer path. Thus, the air above the wing needs to move at a higher speed in order to reconnect with the air that moves below the wing. Bernoulli's Equation then implies that the pressure on the top side of the wing is lower than that on the bottom side. Since the combined surface area of the two wings of a Boeing 747 is $511.\,\mathrm{m}^2$, a pressure difference of $\Delta p = F/A = (3.4\,\mathrm{MN})/(511.\,\mathrm{m}^2) = 6.65\,\mathrm{kPa}$ (6.6% of the atmospheric pressure at sea level) between the bottom and top of the wings would be required for this notion to work out quantitatively.

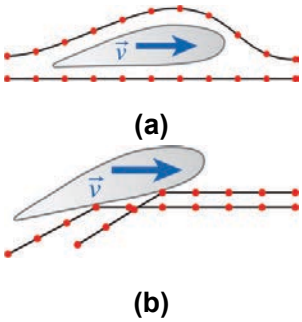

FIGURE 13.42 Two extreme views of the process that creates lift on the wing of an airplane: (a) the Bernoulli effect; (b) Newton's Third Law.

An alternative physical interpretation is shown in Figure 13.42b. In this view, air molecules are deflected downward by the lower side of the wing, and

according to Newton's Third Law, the wing then experiences an upward force that provides the lift. In order for this idea to work, the bottom of the wing has to have some nonzero angle (the angle of attack) relative to the horizontal. (To attain this position, the nose of the aircraft points slightly upward, so the engine thrust also contributes to the lift. Alternatively, the angle of attack can also be realized by changing the angle of the flaps on the wings.)

Both of these simple ideas contain elements of the truth, and the effects contribute to the lift to different degrees, depending on the type of aircraft and the flight phase. The Newtonian effect is more important during takeoff and landing, and during all flight phases for fighter planes (which have a smaller wing area). However, in general, air does not act as an ideal incompressible fluid as it streams around an airplane's wing. It is compressed at the front edge of the wing and decompressed at its back edge. This compression-decompression effect is stronger on the top surface than on the bottom surface, creating a higher net pressure on the bottom of the wing and providing the lift. The design of aircraft wings is still under intense study, and ongoing research seeks to develop new wing designs that can yield higher fuel efficiency and stability.

We can apply similar considerations to the flight of a curveball in baseball. Curveballs have a sideward spin, and if a left-handed pitcher gives a strong clockwise rotation (as seen from above), the ball will deviate to the right relative to a straight line (as seen by the pitcher). In Figure 13.43, the relative velocity between the air and a point on the left surface of the ball is larger than the relative velocity between the air and a point on the right surface. Application of Bernoulli's Equation might cause us to expect the pressure to be lower on the left side of the ball than on the right, thus causing the ball to move left.

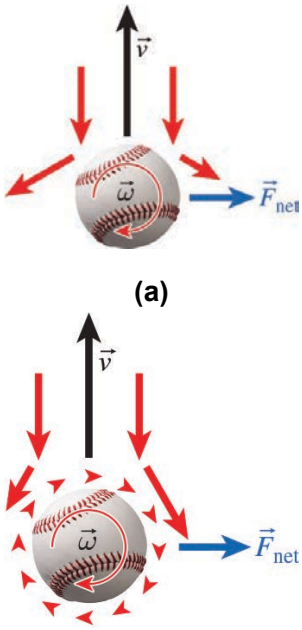

FIGURE 13.43 Top view of clockwise spinning baseball moving from the bottom of the page toward the top of the page: (a) interpretation using Newton's Third Law; (b) explanation involving a boundary layer.

a-b: GoodSportHD.com/Alamy Stock Photo

The interpretation using Newton's Third Law (Figure 13.43a) comes closer to explaining correctly why a clockwise spinning baseball experiences a clockwise deflection. The figure shows a top view of a clockwise spinning baseball, moving from the bottom of the page toward the top, with the air molecules that the ball encounters represented by red arrows. As the air molecules collide with the surface of the ball, those on the side where the surface is rotating toward them (left side in Figure 13.43a) receive a stronger sideways hit, or impulse, than those on the other side. By Newton's Third Law, the net recoil force on the baseball thus deflects the baseball in the same direction as its rotation. While the Newtonian explanation gets the direction of the effect right, it is not quite the correct explanation, because the oncoming

air molecules do not reach the surface of the baseball undisturbed, as is required for this model to work.

Just like the lift of an airplane, the phenomenon of a curveball has a more complex explanation. A rotating sphere moving through air drags a boundary layer of air along with its surface. The air molecules that encounter this boundary layer get dragged along to some extent. This causes the air molecules on the right side of the ball in Figure 13.43b to be accelerated and those on the left side to be slowed down. The differentially higher speed of air on the right side implies a lower pressure due to the Bernoulli effect and thus causes a deflection to the right. This is known as the *Magnus effect*.

In tennis, topspin causes the ball to dip faster than a ball hit without spin; backspin causes the ball to sail longer. Both kinds of effect occur for the same reason as we just noted for the curveball in baseball. Golfers also use backspin to make their drives carry longer. A well-driven golf ball will have backspin of approximately 4000 rpm. Sidespin in golf causes draws or hooks and fades or slices, depending on the severity and direction of the spin. Incidentally, the dimples on a golf ball are essential for its flight characteristics; they cause turbulence around the golf ball and thus reduce the air resistance. Even the best professionals would not be able to hit a golf ball without dimples more than 200 m.

EXAMPLE 13.8 Spray Bottle

PROBLEM

If you squeeze the handle of a spray bottle (Figure 13.44), you cause air to flow horizontally across the opening of a tube that extends down into the liquid almost to the bottom of the bottle. If the air is moving at 50.0 m/s, what is the pressure difference between the top of the tube and the atmosphere? Assume that the density of air is $\rho = 1.20\ \text{kg/m}^3$.

FIGURE 13.44 Spray bottle for dispensing liquids in the form of a fine mist.

Ken Karp/McGraw Hill

SOLUTION

Before you squeeze the handle, the airflow speed is $v_0 = 0$. Using Bernoulli's Equation for a negligible height difference (equation 13.21), we find

$$p + \tfrac{1}{2}\rho v^2 = p_0 + \tfrac{1}{2}\rho v_0^2.$$

Solving this equation for the pressure difference, $p - p_0$, under the condition that $v_0 = 0$, we arrive at

$$p - p_0 = -\tfrac{1}{2}\rho v^2 = -\frac{\left(1.20\ \text{kg/m}^3\right)\left(50.0\ \text{m/s}\right)^2}{2} = -1500\ \text{Pa}.$$

Therefore, we see that the pressure is lowered by 1.50 kPa, causing the liquid to be pushed upward and broken up into small droplets in the air

stream, to form a mist.

The same principle is used in old-fashioned carburetors, which mix the fuel with air in older cars. (In newer cars, the carburetor has been replaced by fuel injectors.)

SOLVED PROBLEM 13.4 Venturi Tube

PROBLEM

On some light aircraft, a device called a *Venturi tube* is used to create a pressure difference that can be used to drive gyroscope-based instruments for navigation. The Venturi tube is mounted on the outside of the fuselage in an area of free airflow. Suppose a Venturi tube has a circular opening with a diameter of 10.0 cm, narrowing down to a circular opening with a diameter of 2.50 cm, and then opening back up to the original diameter of 10.0 cm. What is the pressure difference between the 10-cm opening and the narrowest region of the Venturi tube, assuming that the aircraft is flying at a constant speed of 38.0 m/s at a low altitude where the density of air can be assumed to be that at sea level $\left(\rho = 1.30\ \text{kg/m}^3\right)$ at 5 °C?

SOLUTION

THINK

The equation of continuity (equation 13.18) tells us that the product of the area and the velocity of the flow through the Venturi tube is constant. We can then relate the area of the opening, the area of the narrowest region, the velocity of the air entering the Venturi tube, and the velocity of the air in the narrowest region of the tube. Using Bernoulli's Equation, we can then relate the pressure at the opening to the pressure in the narrowest region.

SKETCH

A Venturi tube is sketched in Figure 13.45.

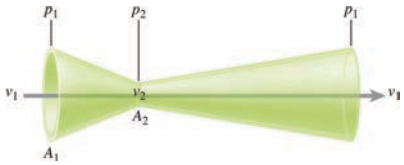

FIGURE 13.45 A Venturi tube with air flowing through it.

RESEARCH

The equation of continuity is

$$A_1 v_1 = A_2 v_2.$$

Bernoulli's Equation tells us that

$$p_1 + \tfrac{1}{2}\rho v_1^2 = p_2 + \tfrac{1}{2}\rho v_2^2.$$

SIMPLIFY

The pressure difference between the opening of the Venturi tube and the narrowest area is found by rearranging the Bernoulli Equation:

$$p_1 - p_2 = \Delta p = \tfrac{1}{2}\rho v_2^2 - \tfrac{1}{2}\rho v_1^2 = \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right).$$

Solving the equation of continuity for v_2 and substituting that result into the rearranged Bernoulli Equation gives us the pressure difference, Δp:

$$\Delta p = \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right) = \tfrac{1}{2}\rho\left[\left(\frac{A_1}{A_2}v_1\right)^2 - v_1^2\right] = \tfrac{1}{2}\rho v_1^2\left(\frac{A_1^2}{A_2^2} - 1\right).$$

Since both areas are circular, we have $A_1 = \pi r_1^2$ and $A_2 = \pi r_2^2$, and thus $(A_1/A_2)^2 = \left(\pi r_1^2/\pi r_2^2\right)^2 = (r_1/r_2)^4$, which leads to

$$\Delta p = \tfrac{1}{2}\rho v_1^2\left[\left(\frac{r_1}{r_2}\right)^4 - 1\right].$$

CALCULATE

Putting in the numerical values, including $\rho = 1.30\,\text{kg/m}^3$ for the density of air, gives us

$$\Delta p = \tfrac{1}{2}\left(1.30\,\text{kg/m}^3\right)(38.30\,\text{m/s})^2\left[\left(\frac{10.0/2\,\text{cm}}{2.5/2\,\text{cm}}\right)^4 - 1\right] = 239{,}343$$

ROUND

We report our result to three significant figures:

$$\Delta p = 239.\,\text{kPa}.$$

DOUBLE-CHECK

The pressure difference between the interior of the airplane and the narrowest part of the Venturi tube is 239 kPa, or more than twice normal

atmospheric pressure. Connecting a hose between the narrowest part of the tube and the interior of the plane thus allows for a steady stream of air through the tube, which can be used to drive a rapidly rotating gyroscope.

Draining a Tank

Let's analyze another simple experiment. A large container with a small hole at the bottom is filled with water and measurements are made of how long it takes to drain. Figure 13.46 illustrates this experiment. We can analyze this process quantitatively and arrive at a description of the height of the fluid column as a function of time. Since the bottle is open at the top, the atmospheric pressure is the same at the upper surface of the fluid column as it is at the small hole. We thus obtain from Bernoulli's Equation (equation 13.19)

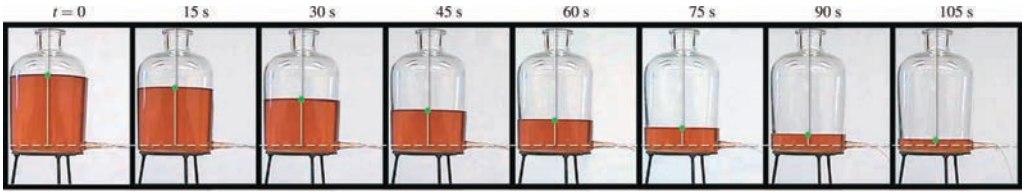

FIGURE 13.46 Draining a bottle of water through a small hole at the base.

W. Bauer and G. D. Westfall

$$\rho g y_1 + \tfrac{1}{2}\rho v_1^2 = \rho g y_2 + \tfrac{1}{2}\rho v_2^2.$$

Canceling out the density and reordering the terms, we obtain

$$v_2^2 - v_1^2 = 2g(y_1 - y_2) = 2gh,$$

where $h = y_1 - y_2$ is the height of the fluid column. We obtained this same result in Chapter 2 for a particle in free fall! Thus, the streaming of an ideal fluid under the influence of gravity proceeds in the same way as free fall of a point particle.

The equation of continuity (equation 13.18) relates the two speeds, v_1 and v_2, to each other via the ratio of their corresponding cross-sectional areas: $A_1 v_1 = A_2 v_2$. Thus, we find the speed with which the fluid flows from the container as a function of the height of the fluid column above the hole:

$$v_1 = v_2 \frac{A_2}{A_1} \Rightarrow v_2^2 - v_1^2 = v_2^2 \left[1 - \frac{A_2^2}{A_1^2}\right] \Rightarrow$$

$$v_2^2 = \frac{2gh}{1 - \dfrac{A_2^2}{A_1^2}} = \frac{2A_1^2 g}{A_1^2 - A_2^2} h.$$

If A_2 is small compared to A_1, this result simplifies to

$$v_2 = \sqrt{2gh}. \tag{13.22}$$

The speed with which the fluid streams from the container is sometimes called the **speed of efflux,** and equation 13.22 is often called *Torricelli's Theorem*.

How does the height of the fluid column change as a function of time? To answer this, we note that the speed v_1 is the negative of the time derivative of the height of the fluid column, h : $v_1 = -dh/dt$, since the height decreases with time. From the equation of continuity, we then find

$$\begin{aligned} A_1 v_1 = -A_1 \frac{dh}{dt} = A_2 v_2 = A_2 \sqrt{2gh} \Rightarrow \\ \frac{dh}{dt} = -\frac{A_2}{A_1}\sqrt{2gh}. \end{aligned} \tag{13.23}$$

Because equation 13.23 relates the height to its derivative, it is a differential equation. Its solution is

$$h(t) = h_0 - \frac{A_2}{A_1}\sqrt{2gh_0}t + \frac{g}{2}\frac{A_2^2}{A_1^2}t^2, \tag{13.24}$$

where h_0 is the initial height of the fluid column. You can convince yourself that equation 13.24 is really the solution by taking its derivative and inserting that into equation 13.23. The derivative is

$$\frac{dh}{dt} = -\frac{A_2}{A_1}\sqrt{2gh_0} + g\frac{A_2^2}{A_1^2}t.$$

The point in time at which this derivative reaches zero is the time at which the draining process has finished:

$$\frac{dh}{dt} = 0 \Rightarrow t_\mathrm{f} = \frac{A_1}{A_2}\sqrt{\frac{2h_0}{g}}. \tag{13.25}$$

If you substitute this expression for t into equation 13.24, you see that t_f is also the time at which the height of the fluid column reaches zero, which is as

expected. Because, according to equation 13.23, the time derivative of the height is proportional to the square root of the height, the height has to be zero when the derivative is zero.

Equation 13.25 also tells us that the time it takes to drain a cylindrical container is proportional to the cross-sectional area of the container and inversely proportional to the area of the hole the liquid is draining through. However, the time is also proportional to the square root of the initial height of the fluid. Thus, if two containers hold the same volume of liquid and drain through holes of the same size, the container that is taller and with a smaller cross-sectional area will drain faster.

Finally, keep in mind that equation 13.25 holds only for an ideal fluid in a container with constant cross-sectional area as a function of height and with a hole whose cross-sectional area is small compared to that of the container.

EXAMPLE 13.9 Draining a Bottle

Figure 13.46 shows a large cylindrical bottle of cross-sectional area $A_1 = 0.100\ \text{m}^2$. The liquid (water with red food coloring) drained through a small hole of radius 7.40 mm, or of area $A_2 = 1.72 \cdot 10^{-4}\ \text{m}^2$. The frames in the figure represent times at 15-s intervals. The initial height of the fluid column above the hole was $h_0 = 0.300\ \text{m}$.

PROBLEM

How long did it take to drain this bottle?

SOLUTION

We can simply use equation 13.25 and insert the given values:

$$t_f = \frac{A_1}{A_2}\sqrt{\frac{2h_0}{g}} = \frac{0.100\ \text{m}^2}{1.72 \cdot 10^{-4}\ \text{m}^2}\sqrt{\frac{2(0.300\ \text{m})}{9.81\ \text{m/s}^2}} = 144\ \text{s}.$$

While the solution to this problem is straightforward, it is instructive to plot the height as a function of time, using equation 13.24, and compare the plot to the experimental data. In Figure 13.46, the level of the hole is marked with a dashed horizontal line, and the height of the fluid column in each frame is marked with a green dot. Figure 13.47 shows the comparison between the calculated solution (the red line) and the data obtained from the experiment. You can see that the agreement is well within the measurement uncertainty, represented by the size of the green dots.

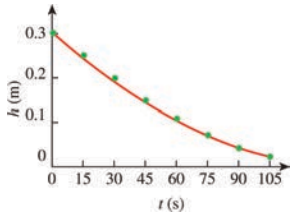

FIGURE 13.47 Height of fluid column as a function of time: Green dots are observed data points; the red line is the calculated solution.

Concept Check 13.8

If the bottle and initial fluid level remain the same as in Example 13.9 but the diameter of the hole is halved, the time required to drain all the fluid will be approximately

a) 36 s.

b) 72 s.

c) 144 s.

d) 288 s.

e) 576 s.

13.7 Viscosity

If you have ever drifted in a boat on a gentle river, you may have noticed that your boat moves faster in the middle of the river than very close to the banks. Why would this happen? If the water in the river were an ideal fluid in laminar motion, it should make no difference how far away from shore you are. However, water is not quite an ideal fluid. Instead, it has some degree of "stickiness," called **viscosity.** For water, the viscosity is quite low; for heavy motor oil, it is significantly higher, and it is even higher yet for substances like honey, which flow very slowly. Viscosity causes the fluid streamlines at the surface of a river to partially stick to the boundary and neighboring streamlines to partially stick to one another.

The velocity profile for the streamlines in viscous flow in a tube is sketched in Figure 13.48b. The profile is parabolic, with the velocity approaching zero at the walls and reaching its maximum value in the center. This flow is still laminar, with the streamlines all flowing parallel to one another.

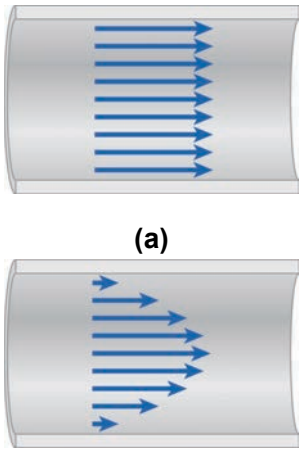

FIGURE 13.48 Velocity profiles in a cylindrical tube: (a) nonviscous ideal fluid flow; (b) viscous flow.

How is the viscosity of a fluid measured? The standard procedure is to use two parallel plates of area A and fill the gap of width h between them with the fluid. Then one of the plates is dragged across the other and the force F that is required to do so is measured. The resulting velocity profile of the fluid flow is linear (Figure 13.49). The viscosity, η, is defined as the ratio of the force per

unit area divided by the velocity difference between the top and bottom plates over the distance between the plates:

$$\eta = \frac{F/A}{\Delta v/h} = \frac{Fh}{A\Delta v}. \tag{13.26}$$

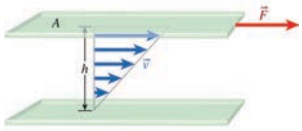

FIGURE 13.49
Measuring the viscosity of a liquid with two parallel plates.

The unit of viscosity represents pressure (force per unit area) multiplied by time, or pascal seconds (Pa s). This unit is also called a *poiseuille* (Pl). [Care must be taken to avoid confusing this SI unit with the cgi unit poise (P), because $1\ \mathrm{P} = 0.1\ \mathrm{Pa\ s}$.]

It is important to realize that the viscosity of any fluid depends strongly on temperature. You can see an example of this temperature dependence in the kitchen. If you store olive oil in the refrigerator and then pour it from the bottle, you can see how slowly it flows. Heat the same olive oil in a pan, and it flows almost as readily as water. Temperature dependence is of great concern for motor oils, and the goal is to have a small temperature dependence. Table 13.5 lists some typical viscosity values for different fluids. All values are those at room temperature $(20\ ^\circ\mathrm{C} = 68\ ^\circ\mathrm{F})$ except that of blood, whose value is given for the physiologically relevant human body temperature $(37\ ^\circ\mathrm{C} = 98.6\ ^\circ\mathrm{F})$. Incidentally, the viscosity of blood increases by about 20% during a human's lifetime, and the average value for men is slightly higher than that for women $\left(4.7 \cdot 10^{-3}\mathrm{Pa\ s}\text{ vs. }4.3 \cdot 10^{-3}\ \mathrm{Pa\ s}\right)$.

Table 13.5 Some Typical Values of Viscosity at Room Temperature

Material	Viscosity (Pa s)
Air	$1.8 \cdot 10^{-5}$
Alcohol (ethanol)	$1.1 \cdot 10^{-3}$
Blood (at body temperature)	4.10^{-3}
Honey	10
Mercury	$1.5 \cdot 10^{-3}$
Motor oil (SAE 10 to SAE 40)	0.06 to 0.7
Olive oil	0.08
Water	$1.0 \cdot 10^{-3}$

The viscosity of a fluid is important in determining how much fluid can flow through a pipe of given radius r and length ℓ. Gotthilf Heinrich Ludwig Hagen (in 1839) and Jean Louis Marie Poiseuille (in 1840) found independently that R_{v}, the volume of fluid that can flow per unit time, is

$$R_{\text{v}} = \frac{\pi r^4 \Delta p}{8\eta\ell}. \tag{13.27}$$

Here Δp is the pressure difference between the two ends of the pipe. As expected, the flow is inversely proportional to the viscosity and the length of the pipe. Most significantly, though, it is proportional to the fourth power of the radius of the pipe. If we consider a blood vessel as a pipe, this relationship helps us understand the problem associated with clogging of the arteries. If cholesterol-induced deposits reduce the diameter of a blood vessel by 50%, then the blood flow through the vessel is reduced to $1/2^4 = 1/16$, or 6.25% of the original rate—a reduction of 93.75%.

EXAMPLE 13.10 Hypodermic Needle

For many people, the scariest part of a visit to the doctor is an injection. Learning about the fluid mechanics of the hypodermic needle (Figure 13.50) won't change that, but is interesting nonetheless.

FIGURE 13.50 A hypodermic needle illustrates fluid flow with viscosity.

Siede Preis/Getty Images

PROBLEM 1

If $2.0\,\text{cm}^3$ of water is to be pushed out of a 1.0-cm-diameter syringe through a 3.5-cm-long 15-gauge needle (interior needle diameter $= 1.37\,\text{mm}$) in 0.4 s, what force must be applied to the plunger of the syringe?

SOLUTION 1

The Hagen-Poiseuille Law (equation 13.27) relates fluid flow to the pressure difference causing the flow. We can solve that equation for the pressure difference, Δp, between the tip of the needle and the end that is connected to the syringe:

$$\Delta p = \frac{8\eta\ell R_\text{v}}{\pi r^4}.$$

The viscosity of water can be obtained from Table 13.5: $\eta = 1.0 \cdot 10^{-3}\text{Pa s}$. The flow rate, R_v, is just the ratio of volume to time:

$$R_\text{v} = \frac{\Delta V}{\Delta t} = \frac{2.0 \cdot 10^{-6}\ \text{m}^3}{0.4\,\text{s}} = 5.0 \cdot 10^{-6}\ \text{m}^3/\text{s}.$$

The geometric dimensions of the syringe are specified in the problem statement, so we obtain

$$\Delta p = \frac{8\left(1.0 \cdot 10^{-3}\,\text{Pa s}\right)\left(0.035\ \text{m}\right)\left(5.0 \cdot 10^{-6}\ \text{m}^3/\text{s}\right)}{\pi\left[0.5\left(1.37 \cdot 10^{-3}\ \text{m}\right)\right]^4} = 2024\,\text{Pa}.$$

Because pressure is force per unit area, we can obtain the required force by multiplying the pressure difference we just calculated by the appropriate area. What is this area? The required force is provided by pushing on the plunger, so we use the area of the plunger:

$$A = \pi R^2 = \pi[0.5(0.01\ \text{m})]^2 = 7.8 \cdot 10^{-5}\ \text{m}^2.$$

Thus, the force required to push out 2.0 cm^3 of water in 0.4 s is only

$$F = A\Delta p = \left(7.8 \cdot 10^{-5}\ \text{m}^2\right)(2024\ \text{Pa}) = 0.16\ \text{N}.$$

PROBLEM 2

What is the speed with which the water emerges from the needle of the syringe?

Page 424

SOLUTION 2

We saw in Section 13.6 that the speed of fluid flow is related to the volume rate of flow by $R_\text{v} = Av$, where A is the cross-sectional area—in this case, the area of the needle tip whose diameter is 1.37 mm. Solving this equation for the speed, we find

$$v = \frac{R_\text{v}}{A} = \frac{5.0 \cdot 10^{-6}\ \text{m}^3/\text{s}}{\pi\left[0.5\left(1.37 \cdot 10^{-3}\ \text{m}\right)\right]^2} = 3.4\ \text{m/s}.$$

DISCUSSION

If you have ever pushed the plunger of a syringe, you know it takes more force than 0.16 N. (A force of 0.16 N is equivalent to the weight of a cheap ballpoint pen.) What gives rise to the higher force requirement? Remember that the plunger has to provide a tight seal with the wall of the syringe. Thus, the main effort in pushing the plunger results from overcoming the friction force between the syringe wall and the plunger. It would be an altogether different story, though, if the syringe were filled with honey. Note also that the 15-gauge needle used in this example is larger than the needle typically used to make an injection, which is a 24- or 25-gauge needle.

13.8 Turbulence and Research Frontiers in Fluid Flow

In laminar flow, the streamlines of a fluid follow smooth paths. In contrast, for a fluid in turbulent flow, vortices form, detach, and propagate (Figure 13.51). We have already seen that ideal laminar flow or viscous laminar flow transitions into turbulent flow when the velocity of flow exceeds a certain value. This transition is clearly illustrated in Figure 13.33b, which shows how rising cigarette smoke undergoes a transition from laminar to turbulent flow. What is the criterion that determines whether flow is laminar or turbulent?

FIGURE 13.51
Extreme turbulent flow —a tornado is a vortex.

Sergey Nivens/Shutterstock

The answer lies in the **Reynolds number,** Re, which is the ratio of the typical inertial force to the viscous force and thus is a pure dimensionless number. The inertial force has to be proportional to the density, ρ, and the typical velocity of the fluid, $\overline{v}$, because $F = dp/dt$, according to Newton's Second Law. The viscous force is proportional to the viscosity, η, and inversely proportional to the characteristic length scale, L, over which the flow varies. For flow through a pipe with a circular cross section, this length scale is the diameter of the pipe, $L = 2r$. Thus, the formula for calculating the Reynolds number is

$$\mathrm{Re} = \frac{\rho \overline{v} L}{\eta}. \tag{13.28}$$

As a rule of thumb, a Reynolds number less than 2000 means laminar flow, and one higher than 4000 means turbulent flow. For Reynolds numbers between 2000 and 4000, the character of the flow depends on many fine details of the exact configuration. Engineers try hard to avoid this interval because of this essential unpredictability.

The true power of the Reynolds number lies in the fact that fluid flows in systems with the same geometry and the same Reynolds number behave similarly. This allows engineers to reduce typical length scales or velocity scales, build scale models of boats or airplanes, and test their performance in water tanks or wind tunnels of relatively modest scale (Figure 13.52).

(a) (b)

FIGURE 13.52 (a) Wind-tunnel testing of a scale model of a wing. (b) Scale model of fighter jet with interchangeable parts for wind-tunnel testing.

a: Kim Steele/Getty Images; **b:** W. Bauer and G. D. Westfall

Rather than scale models, modern research on fluid flow and turbulence relies on computer models. Hydrodynamic modeling is employed for studying applications of an incredible variety of physical systems, such as the performance and aerodynamics of cars, airplanes, rockets, and boats. The wake effects of wind turbines, which can be seen in Figure 13.1, are a particularly important area of current study. However, hydrodynamic modeling is also utilized in studying the collisions of atomic nuclei at the highest energies attainable in modern accelerators and in the modeling of supernova explosions (Figure 13.53). In 2005, an experimental group working at the Relativistic Heavy Ion Collider in Brookhaven, New York, discovered that gold nuclei show the characteristics of a perfect nonviscous fluid when they smash into each other at the highest attainable energies. [One of the authors (Westfall) had the privilege to announce this discovery at the 2006 annual meeting of the American Physical Society.] Exciting research results on fluid motion will continue to emerge over the next decades, as this is one of the most interesting interdisciplinary areas in the physical sciences.

WHAT WE HAVE LEARNED | EXAM STUDY GUIDE

- One mole of a material has $N_\mathrm{A} = 6.022 \cdot 10^{23}$ atoms or molecules. The mass of 1 mol of a material in grams is given by the sum of the atomic mass numbers of the atoms that make up the material.
- For a solid, stress $=$ modulus $\cdot$ strain, where stress is force per unit area and strain is a unit deformation. There are three types of stress and strain, each with its own modulus:
  - Tension or linear compression leads to a positive or negative change in length: $\frac{F}{A} = Y\frac{\Delta L}{L}$, where Y is Young's modulus.
  - Volume compression leads to a change in volume: $\frac{F}{A} = B\frac{\Delta V}{V}$, where B is the bulk modulus.
  - Shear leads to bending: $\frac{F}{A} = G\frac{\Delta x}{L}$, where G is the shear modulus.
- Pressure is defined as force per unit area: $p = \frac{F}{A}$.
- The absolute pressure, p, at a depth h in a liquid with density ρ and pressure p_0 on its surface is $p = p_0 + \rho g h$.
- Gauge pressure is the difference in pressure between the gas in a container and the pressure of Earth's atmosphere.
- Pascal's Principle states that when a change in pressure occurs at any point in a confined incompressible fluid, an equal change in pressure occurs at every point in the fluid.
- The buoyant force on an object immersed in a fluid is equal to the weight of the fluid displaced: $F_\mathrm{B} = m_\mathrm{f} g$.
- An ideal fluid is assumed to exhibit flow that is laminar, incompressible, nonviscous, and irrotational.
- The flow of an ideal fluid follows streamlines.
- The equation of continuity for a flowing ideal fluid relates the velocity and the area of the fluid flowing through a container or pipe: $A_1 v_1 = A_2 v_2$.
- Bernoulli's Equation relates the pressure, height, and velocity of an ideal fluid flowing through a container or pipe: $p + \rho g y + \frac{1}{2}\rho v^2 = \text{constant}$.

- For viscous fluids, the viscosity, η, is the ratio of the force per unit area to the velocity difference per unit length: $\eta = \dfrac{F/A}{\Delta v/h} = \dfrac{Fh}{A\Delta v}$.
- For viscous fluids, the volume flow rate through a cylindrical pipe of radius r and length ℓ is given by $R_\text{v} = \dfrac{\pi r^4 \Delta p}{8\eta\ell}$, where Δp is the pressure difference between the two ends of the pipe.
- The Reynolds number determines the ratio of inertial force to viscous force and is defined as $\text{Re} = \dfrac{\rho \bar{v} L}{\eta}$, where $\bar{v}$ is the average fluid velocity and L is the characteristic length scale over which the flow changes. A Reynolds number less than 2000 means laminar flow, and one greater than 4000 means turbulent flow.

ANSWERS TO SELF-TEST OPPORTUNITIES

13.1 The volume of the water in the bottle is 500 cm^3. The density of water is 1 g/cm^3. Thus, the bottle contains 500 g of water. The mass of 1 mol of water is 18.02 g, so $n = (500\text{ g})/(18.02\text{ g/mol}) = 27.7\text{mol}$. Thus, $N = n \cdot N_\text{A} = 27.7\left(6.022 \cdot 10^{23}\text{ mol}^{-1}\right) = 1.67 \cdot 10^{25}$ molecules.

13.2
$$\rho_\text{H} = \frac{2\text{ g}}{22.4\text{ L}} = 0.089\text{ g/L} = 0.089\text{ kg/m}^3$$
$$\rho_\text{He} = \frac{4\text{ g}}{22.4\text{ L}} = 0.18\text{ g/L} = 0.18\text{ kg/m}^3$$

13.3
$$\begin{aligned} W &= F_\text{B} = W_\text{baloon} = \rho_{20}Vg - \rho_\text{He}Vg \\ &= Vg(\rho_{20} - \rho_{100}) = \left(2200\text{ m}^3\right)\left(9.81\text{m/s}^2\right)\left(1.205\text{ kg/m}^3 - 0.164\text{ kg/m}^3\right) \\ &= 22{,}500\text{ N, or }5050\text{ lb}_\text{f}. \end{aligned}$$

13.4 The mass of the ball is the difference between the measurements in part (d) and part (a) of Figure 13.29: $m_\text{b} = m_2 - m_0 = 0.159$ kg.

PROBLEM-SOLVING GUIDELINES: SOLIDS AND FLUIDS

1. The three types of stress all have the same relationship with strain: The ratio of stress to strain equals a constant for the material, which can be Young's modulus, the bulk modulus, or the shear modulus. Be sure you understand what kind of stress is acting in a particular situation.

2. Remember that the buoyant force is exerted by a fluid on an object floating or submerged in it. The net force depends on the density of the object as well as the density of the fluid; you will often need to calculate mass and volume separately and take their ratio to obtain a value for the density.

3. Bernoulli's Equation is derived from the work-energy theorem, and the main problem-solving guidelines for energy problems apply to flow problems as well. In particular, be sure to clearly identify where point 1 and point 2 are located for applying Bernoulli's Equation and to list known values for pressure, height, and velocity of the fluid at each point.

MULTIPLE-CHOICE QUESTIONS

13.1 Salt water has a greater density than fresh water. A boat floats in both fresh water and salt water. The buoyant force on the boat in salt water is _____ that in fresh water.

a) equal to

b) smaller than

c) larger than

13.2 You fill a tall glass with ice and then add water to the level of the glass's rim, so some fraction of the ice floats above the rim. When the ice melts, what happens to the water level? (Neglect evaporation, and assume that the ice and water remain at 0°C during the melting process.)

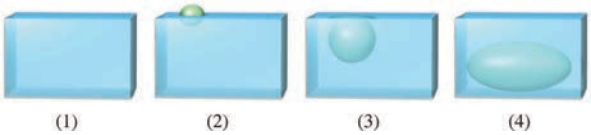
a) The water overflows the rim.

b) The water level drops below the rim.

c) The water level stays at the rim.

d) It depends on the difference in density between water and ice.

13.3 The figure shows four identical open-top tanks filled to the brim with water and sitting on a scale. Balls float in tanks (2) and (3), but an object sinks to the bottom in tank (4). Which of the following correctly ranks the weights shown on the scales?



a) $(1) < (2) < (3) < (4)$

b) $(1) < (2) = (3) < (4)$

c) $(1) < (2) = (3) = (4)$

d) $(1) = (2) = (3) < (4)$

13.4 You are in a boat filled with large rocks in the middle of a small pond. You begin to drop the rocks into the water. What happens to the water level of the pond?

a) It rises.

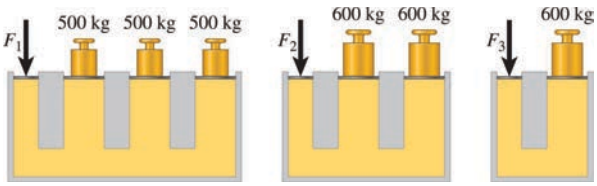
b) It falls.

c) It doesn't change.

d) It rises momentarily and then falls when the rocks hit bottom.

e) There is not enough information to say.

13.5 Rank in order, from largest to smallest, the magnitudes of the forces F_1, F_2, and F_3 required for balancing the masses shown in the figure.



13.6 In a horizontal water pipe that narrows to a smaller radius, the velocity of the water in the section with the smaller radius will be larger. What happens to the pressure?

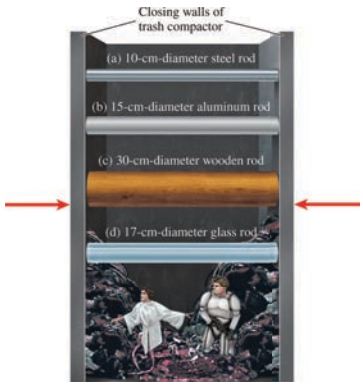
a) The pressure will be the same in both the wider and narrower sections of the pipe.

b) The pressure will be higher in the narrower section of the pipe.

c) The pressure will be higher in the wider section of the pipe.

d) It is impossible to tell.

13.7 In one of the *Star Wars*™ movies, four of the heroes are trapped in a trash compactor on the Death Star. The compactor's walls begin to close in, and the heroes need to pick an object from the trash to place between the closing walls to stop them. All the objects are the same length and have a circular cross section, but their diameters and compositions are different. Assume that each object is oriented horizontally and does not bend. They have the time and strength to hold up only one object between the walls. Which of the objects shown in the figure will work best—that is, will withstand the greatest force per unit of compression?



13.8 Many altimeters determine altitude changes by measuring changes in the air pressure. An altimeter that is designed to be able to detect altitude changes of 100 m near sea level should be able to detect pressure changes of

a) approximately 1 Pa.

b) approximately 10 Pa.

c) approximately 100 Pa.

d) approximately 1 kPa.

e) approximately 10 kPa.

13.9 Which of the following assumptions is *not* made in the derivation of Bernoulli's Equation?

a) Streamlines do not cross.

b) There is negligible viscosity.

c) There is negligible friction.

d) There is no turbulence.

e) There is negligible gravity.

13.10 A beaker is filled with water to the rim. Gently placing a plastic toy duck in the beaker causes some of the water to spill out. The weight of the beaker with the duck floating in it is

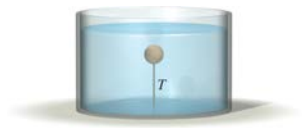
a) greater than the weight before adding the duck.

b) less than the weight before adding the duck.

c) the same as the weight before adding the duck.

d) greater or less than the weight before the duck was added, depending on the weight of the duck.

13.11 A piece of cork $\left(\text{densisty} = 0.33\ \text{g/cm}^3\right)$ with a mass of 10 g is held in place under water by a string, as shown in the figure. What is the tension, *T*, in the string?



a) 0.10 N

b) 0.20 N

c) 0.30 N

d) 100 N

e) 200 N

f) 300 N

13.12 Suppose you pump the air out of a paint can, which is covered by a lid. The can is cylindrical, with a height of 22.4 cm and a diameter of 16.0 cm. How much force does the atmosphere exert on the lid of the evacuated paint can?

a) 9.81 N

b) 511 N

c) 2030 N

d) 8120 N

13.13 A steel sphere with a diameter of 0.250 m is submerged in the ocean to a depth of 500.0 m. What is the percentage change in the volume of the sphere? The bulk modulus of steel is $160 \cdot 10^9$ Pa.

a) 0.0031%

b) 0.045%

c) 0.33%

d) 0.55%

e) 1.5%

13.14 A flowing fluid has a Reynolds number of 1000. Which statement about this flow is true?

a) It is laminar flow.

b) It is turbulent flow.

c) It is frictionless flow.

d) It is perfect flow.

e) It is nonviscous flow.

13.15 A beaker of water is sitting on a scale. A steel ball hanging from a string is lowered into the water until the ball is completely submerged but is not touching the beaker. The weight registered by the scale will

a) increase.

b) decrease.

c) stay the same.

CONCEPTUAL QUESTIONS

13.16 You know from experience that if a car you are riding in suddenly stops, heavy objects in the rear of the car move toward the front. Why does a helium-filled balloon in such a situation move, instead, toward the rear of the car?

13.17 A piece of paper is folded in half and then opened up and placed on a flat table so that it "peaks" up in the middle as shown in the figure. If you blow air between the paper and the table, will the paper move up or down? Explain.

13.18 In what direction does a force due to water flowing from a showerhead act on a shower curtain, inward toward the shower or outward? Explain.

13.19 Point out and discuss any flaws in the following statement: *The hydraulic car lift is a device that operates on the basis of Pascal's Principle. Such a device can produce large output forces with small input forces. Thus, with a small amount of work done by the input force, a much larger amount of work is produced by the output force, and the heavy weight of a car can be lifted.*

13.20 Given two springs of identical size and shape, one made of steel and the other made of aluminum, which has the higher spring constant? Why? Does the difference depend more on the shear modulus or the bulk modulus of the material?

13.21 One material has a higher density than another. Are the individual atoms or molecules of the first material necessarily more massive than those of the second?

13.22 Analytic balances are calibrated to give correct mass values for such items as steel objects of density $\rho_s = 8000.00\ \text{kg/m}^3$. The calibration compensates for the buoyant force arising because the measurements are made in air, of density $\rho_a = 1.205\ \text{kg/m}^3$. What compensation must be made to measure the masses of objects of a different material, of density ρ? Does the buoyant force of air matter?

13.23 If you turn on the faucet in the bathroom sink, you will observe that the stream seems to narrow from the point at which it leaves the spigot to the point at which it hits the bottom of the sink. Why does this occur?

13.24 In many problems involving application of Newton's Second Law to the motion of solid objects, friction is neglected for the sake of making the solution easier. The counterpart of friction between solids is viscosity of liquids. Do problems involving fluid flow become simpler if viscosity is neglected? Explain.

13.25 You have two identical silver spheres and two unknown fluids, A and B. You place one sphere in fluid A, and it sinks; you place the other sphere in fluid B, and it floats. What can you conclude about the buoyant force of fluid A versus that of fluid B?

13.26 Water flows from a circular faucet opening of radius r_0, directed vertically downward, at speed v_0. As the stream of water falls, it narrows. Find an expression for the radius of the stream as a function of distance fallen, $r(y)$, where y is measured downward from the opening. Neglect the eventual breakup of the stream into droplets, and any resistance due to drag or viscosity.

EXERCISES

A blue problem number indicates a worked-out solution is available in the Student Solutions Manual. One • and two •• indicate increasing level of problem difficulty.

Sections 13.1 and 13.2

13.27 Air consists of molecules of several types, with an average molar mass of 28.95 g. About how many molecules does an adult who inhales 0.50 L of air at sea level take in?

•**13.28** Ordinary table salt (NaCl) consists of sodium and chloride ions arranged in a *face-centered cubic crystal lattice*. That is, a sodium chloride crystal consists of cubic unit cells with a sodium ion on each corner and at the center of each face, and a chloride ion at the center of the cube and at the midpoint of each edge. The density of sodium chloride is $2.165 \cdot 10^3\ \mathrm{kg/m^3}$. Calculate the spacing between adjacent sodium and chloride ions in the crystal.

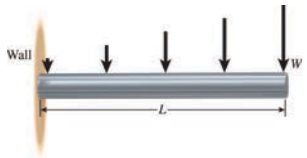
Section 13.3

13.29 A 20-kg chandelier is suspended from a ceiling by four vertical steel wires. Each wire has an unloaded length of 1 m and a diameter of 2 mm, and each bears an equal load. When the chandelier is hung, how far do the wires stretch?

13.30 Find the minimum diameter of a 50.0-m-long nylon string that will stretch no more than 1.00 cm when a load of 70.0 kg is suspended from its lower end. Assume that $Y_{\text{nylon}} = 3.51 \cdot 10^9\ \text{N/m}^2$.

13.31 A 2.00-m-long steel wire in a musical instrument has a radius of 0.300 mm. When the wire is under a tension of 90.0 N, how much does its length change?

•**13.32** A rod of length L is attached to a wall. The load on the rod increases linearly (as shown by the arrows in the figure) from zero at the left end to W newtons per unit length at the right end. Find the shear force at



a) the right end,

b) the center, and

c) the left end.

•• **13.33** Challenger Deep in the Marianas Trench of the Pacific Ocean is the deepest known spot in the Earth's oceans, at 10.922 km below sea level. Taking the density of seawater at atmospheric pressure ($p_0 = 101.3\ \text{kPa}$) to be $1024\ \text{kg/m}^3$ and its bulk modulus to be $B(p) = B_0 + 6.67(p - p_0)$, with $B_0 = 2.19 \cdot 10^9\ \text{Pa}$, calculate the pressure and the density of the seawater at the bottom of Challenger Deep. Disregard variations in water temperature and salinity with depth. Is it a good approximation to treat the density of seawater as essentially constant?

Section 13.4

13.34 How much force is the air exerting on the front cover of your textbook? What mass has a weight equivalent to this force?

13.35 Blood pressure is usually reported in millimeters of mercury (mmHg) or the height of a column of mercury producing the same pressure value. Typical values for an adult human are 130/80; the first value is the *systolic* pressure, during the contraction of the ventricles of the heart, and the second is the *diastolic* pressure, during the contraction of the auricles of the heart. The head of an adult male giraffe is 6.0 m above the ground; the giraffe's heart is 2.0 m above the ground. What is the minimum systolic pressure (in mmHg) required at the heart to drive blood to the head (neglect the additional pressure required to overcome the effects of viscosity)? The density of giraffe blood is $1.00\ \mathrm{g/cm^3}$, and that of mercury is $13.6\ \mathrm{g/cm^3}$.

13.36 A scuba diver must decompress after a deep dive to allow excess nitrogen to exit safely from the bloodstream. The length of time required for decompression depends on the total change in pressure that the diver experienced. Find this total change in pressure for a diver who starts at a depth of $d = 20.0\ \mathrm{m}$ in the ocean $\left(\text{densisty of seawater} = 1024\ \mathrm{kg/m^3}\right)$ and then travels aboard a small plane (with an unpressurized cabin) that rises to an altitude of $h = 5000.\ \mathrm{m}$ above sea level.

•**13.37** A child loses his balloon, which rises slowly into the sky. If the balloon is 20.0 cm in diameter when the child loses it, what is its diameter at an altitude of (a) 1000. m, (b) 2000. m, and (c) 5000. m? Assume that the balloon is very flexible, allowing surface tension to be neglected.

•**13.38** The atmosphere of Mars exerts a pressure of only 600. Pa on the surface and has a density of only $0.0200\ \mathrm{kg/m^3}$.

a) What is the thickness of the Martian atmosphere, assuming the boundary between atmosphere and outer space to be the point where atmospheric pressure drops to 0.0100% of its value at surface level?

b) What is the atmospheric pressure at the bottom of Mars's Hellas Planitia canyon, at a depth of 8.18 km?

c) What is the atmospheric pressure at the top of Mars's Olympus Mons volcano, at a height of 21.3 km?

d) Compare the relative change in air pressure, $\Delta p/p$, between these two points on Mars and between the equivalent extremes on Earth—the Dead Sea shore, at 400. m below sea level, and Mount Everest, at an altitude of 8850 m.

•**13.39** The air density at the top of Mount Everest ($h_{\mathrm{Everest}} = 8850\ \mathrm{m}$) is 34.8% of the air density at sea level. If the air *pressure* at the top of Mount

McKinley in Alaska is 47.7% of the air pressure at sea level, calculate the height of Mount McKinley, using only the information given here.

•**13.40** A sealed vertical cylinder of radius R and height $h = 0.60$ m is initially filled halfway with water, and the upper half is filled with air. The air is initially at standard atmospheric pressure, $p_0 = 1.01 \cdot 10^5$ Pa. A small valve at the bottom of the cylinder is opened, and water flows out of the cylinder until the reduced pressure of the air in the upper part of the cylinder prevents any further water from escaping. By what distance is the depth of the water lowered? (Assume that the temperature of water and air do not change and that no air leaks into the cylinder.)

•• **13.41** A temporary above-ground square pool with 100.-m-long sides is created in a concrete parking lot. The walls are concrete, are 50.0 cm thick, and have a density of 2.50 g/cm^3. The coefficient of static friction between the walls and the parking lot is 0.450. What is the maximum possible depth of water in the pool?

•• **13.42** The calculation of atmospheric pressure at the summit of Mount Everest carried out in Example 13.3 used the model known as the *isothermal atmosphere*, in which gas pressure is proportional to density: $p = \gamma\rho$, with γ constant. Consider a spherical cloud of gas supporting itself under *its own* gravitation and following this model.

a) Write the equation of hydrostatic equilibrium for the cloud, in terms of the gas density as a function of radius, $\rho(r)$.

b) Show that $\rho(r) = \alpha/r^2$ is a solution of this equation, for an appropriate choice of constant α. Explain why this solution is not suitable as a model of a star.

Section 13.5

13.43 A racquetball with a diameter of 5.6 cm and a mass of 42 g is cut in half to make a boat for American pennies made after 1982. The mass and volume of an American penny made after 1982 are 2.5 g and 0.36 cm^3. How many pennies can be placed in the racquetball boat without sinking it?

13.44 A future supertanker filled with oil has a total mass of $10.2 \cdot 10^8$ kg. If the dimensions of the ship are those of a rectangular box 250. m long, 80.0 m wide, and 80.0 m high, determine how far the bottom of the ship is below sea level $(\rho_{sea} = 1024\ kg/m^3)$.

13.45 A box with a volume $V = 0.0500\ m^3$ lies at the bottom of a lake whose water has a density of $1.00 \cdot 10^3 kg/m^3$. How much force is required to lift the box, if the mass of the box is (a) 1000. kg, (b) 100. kg, and (c) 55.0 kg?

•**13.46** A man of mass 64 kg and density 970 kg/m^3 stands in a shallow pool with 32% of the volume of his body below water. Calculate the normal force that the bottom of the pool exerts on his feet.

•**13.47** A block of cherry wood that is 20.0 cm long, 10.0 cm wide, and 2.00 cm thick has a density of 800. kg/m^3. What is the volume of a piece of iron that, if glued to the bottom of the block, makes the block float in water with its top just at the surface of the water? The density of iron is 7860 kg/m^3, and the density of water is 1000. kg/m^3.

•**13.48** The average density of the human body is 985 kg/m^3, and the typical density of seawater is about 1024 kg/m^3.

a) Draw a free-body diagram of a human body floating in seawater and determine what percentage of the body's volume is submerged.

b) The average density of the human body, after maximum inhalation of air, changes to 945 kg/m^3. As a person floating in seawater inhales and exhales slowly, what percentage of his volume moves up out of and down into the water?

c) The Dead Sea (a saltwater lake between Israel and Jordan) is the world's saltiest large body of water. Its average salt content is more than six times that of typical seawater, which explains why there is no plant and animal life in it. Two-thirds of the volume of the body of a person floating in the Dead Sea is observed to be submerged. Determine the density (in kg/m^3) of the seawater in the Dead Sea.

•**13.49** A tourist of mass 60.0 kg notices a chest with a short chain attached to it at the bottom of the ocean. Imagining the riches it could contain, he decides

to dive for the chest. He inhales fully, thus setting his average body density to $945\ \text{kg/m}^3$, jumps into the ocean $\left(\text{with saltwater density} = 1024\ \text{kg/m}^3\right)$, grabs the chain, and tries to pull the chest to the surface. Unfortunately, the chest is too heavy and will not move. Assume that the man does not touch the bottom.

a) Draw the man's free-body diagram, and determine the tension on the chain.

b) What mass (in kg) has a weight that is equivalent to the tension force in part (a)?

c) After realizing he cannot free the chest, the tourist releases the chain. What is his upward acceleration (assuming that he simply allows the buoyant force to lift him up to the surface)?

•**13.50** A very large balloon with mass $M = 10.0\ \text{kg}$ is inflated to a volume of $20.0\ \text{m}^3$ using a gas of density $\rho_{\text{gas}} = 0.20\ \text{kg/m}^3$. What is the maximum mass m that can be tied to the balloon using a 2.00-kg piece of rope without the balloon falling to the ground? (Assume that the density of air is $1.30\ \text{kg/m}^3$ and that the volume of the gas is equal to the volume of the inflated balloon).

•**13.51** The *Hindenburg*, the German zeppelin that caught fire in 1937 while docking in Lakehurst, New Jersey, was a rigid duralumin-frame balloon filled with $2.000 \cdot 10^5\ \text{m}^3$ of hydrogen. The *Hindenburg*'s useful lift (beyond the weight of the zeppelin structure itself) is reported to have been $1.099 \cdot 10^6\ \text{N}$ (or 247,000 lb). Use $\rho_{\text{air}} = 1.205\ \text{kg/m}^3$, $\rho_{\text{H}} = 0.08988\ \text{kg/m}^3$, and $\rho_{\text{He}} = 0.1786\ \text{kg/m}^3$.

a) Calculate the weight of the zeppelin structure (without the hydrogen gas).

b) Compare the useful lift of the (highly flammable) hydrogen-filled *Hindenburg* with the useful lift the *Hindenburg* would have had if it had been filled with (nonflammable) helium, as originally planned.

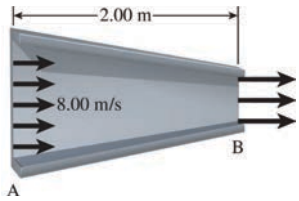
•• **13.52** Brass weights are used to weigh an aluminum object on an analytical balance. The weighing is done one time in dry air and another time in humid air. What should the mass of the object be to produce a noticeable difference in the balance readings, provided the balance's sensitivity is $m_0 = 0.100\ \text{mg}$? (The density of aluminum is $\rho_{\text{A}} = 2.70 \cdot 10^3\ \text{kg/m}^3$; the density of brass is $\rho_{\text{B}} = 8.50 \cdot 10^3\ \text{kg/m}^3$. The density of the dry air is $1.2285\ \text{kg/m}^3$. and the density of the humid air is $1.2273\ \text{kg/m}^3$.)

Section 13.6

13.53 A fountain sends water to a height of 100. m. What is the difference between the pressure of the water just before it is released upward and the atmospheric pressure?

13.54 Water enters a horizontal pipe with a rectangular cross section at a speed of 1.00 m/s. The width of the pipe remains constant but the height decreases. Twenty meters from the entrance, the height is half of what it is at the entrance. If the water pressure at the entrance is 3000. Pa, what is the pressure 20.0 m downstream?

•13.55 Water at room temperature flows with a constant speed of 8.00 m/s through a nozzle with a square cross section, as shown in the figure. Water enters the nozzle at point A and exits the nozzle at point B. The lengths of the sides of the square cross section at A and B are 50.0 cm and 20.0 cm, respectively.

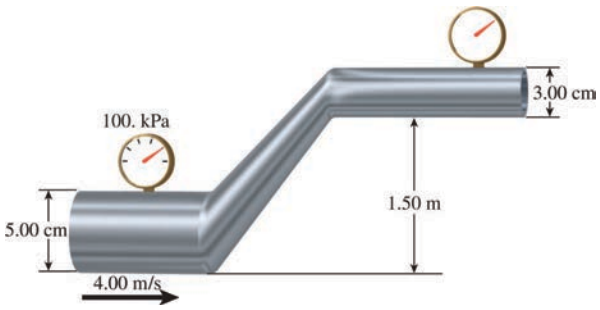


a) What is the volume flow rate at the exit?

b) What is the acceleration at the exit? The length of the nozzle is 2.00 m.

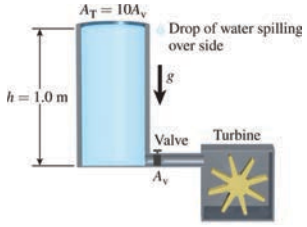
c) If the volume flow rate through the nozzle is increased to 6.00 m^3/s, what is the acceleration of the fluid at the exit?

•13.56 Water is flowing in a pipe as depicted in the figure. What pressure is indicated on the upper pressure gauge?

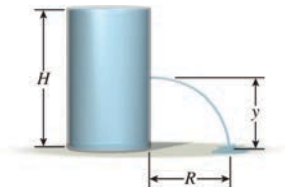


•13.57 An open-topped tank completely filled with water has a release valve near its bottom. The valve is 1.0 m below the water surface. Water is released from the valve to power a turbine, which generates electricity. The area of the top of the tank, A_T, is 10 times the cross-sectional area, A_V, of the valve opening. Calculate the speed of the water as it exits the valve. Neglect friction and viscosity. In addition, calculate the speed of a drop of water released from

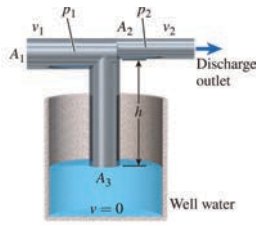
rest at $h = 1.0$ m when it reaches the elevation of the valve. Compare the two speeds.



•13.58 A tank of height H is filled with water and sits on the ground, as shown in the figure. Water squirts from a hole at a height y above the ground and has a range R. For two y values, 0 and H, R is zero. Determine the value of y for which the range will be a maximum.



••13.59 A water-powered backup sump pump uses tap water at a pressure of 3.00 atm $\left(p_1 = 3p_{\text{atm}} = 3.03 \cdot 10^5 \text{ Pa}\right)$ to pump water out of a well, as shown in the figure $(p_{\text{well}} = p_{\text{atm}})$. This system allows water to be pumped out of a basement sump well when the electric pump stops working during an electrical power outage. Using water to pump water may sound strange at first, but these pumps are quite efficient, typically pumping out 2.00 L of well water for every 1.00 L of pressurized tap water. The supply water moves to the right in a large pipe with cross-sectional area A_1 at a speed $v_1 = 2.05\text{m/s}$. The water then flows into a pipe of smaller diameter with a cross-sectional area that is ten times smaller $(A_2 = A_1/10)$.



a) What is the speed v_2 of the water in the smaller pipe, with area A_2?

b) What is the pressure p_2 of the water in the smaller pipe, with area A_2?

c) The pump is designed so that the vertical pipe, with cross-sectional area A_3, that leads to the well water also has a pressure of p_2 at its top. What is the maximum height, h, of the column of water that the pump can support (and therefore act on) in the vertical pipe?

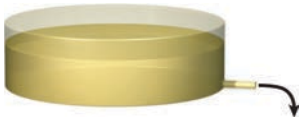
Section 13.7

13.60 A basketball of circumference 75.5 cm and mass 598 g is forced to the bottom of a swimming pool and then released. After initially accelerating upward, it rises at a constant velocity.

a) Calculate the buoyant force on the basketball.

b) Calculate the drag force the basketball experiences while it is moving upward at constant velocity.

•**13.61** The cylindrical container shown in the figure has a radius of 1.00 m and contains motor oil with a viscosity of 0.300 Pa s and a density of 670. kg m^{-3}. Oil flows out of the 20.0 cm long, 0.200 cm diameter tube at the bottom of the container. How much oil flows out of the tube in a period of 10.0 s if the container is originally filled to a height of 0.500 m?



Additional Exercises

13.62 Estimate the atmospheric pressure inside Hurricane Rita. The wind speed was 290 km/h.

13.63 The following data are obtained for a car: The tire pressure is measured as 28.0 psi, and the width and length of the contact surface of each tire are 7.50 in and 8.75 in, respectively. What is the approximate weight of the car?

13.64 Calculate the ratio of the lifting powers of helium (He) gas and hydrogen (H_2) gas under identical circumstances. Assume that the molar mass of air is 28.95 g/mol.

13.65 Water is poured into a large barrel whose height is 2.0 m; a cylindrical, 3.0-cm-diameter cork is stuck into the side at a height of 0.50 m above the ground. As the water level in the barrel just reaches maximum height, the cork flies out of the barrel.

a) What was the magnitude of the static friction force between the barrel and the cork?

b) If the barrel were filled with seawater, would the cork have flown out before the barrel's full capacity was reached?

13.66 In a hydraulic lift, the maximum gauge pressure is 17.00 atm. If the diameter of the output line is 22.5 cm, what is the heaviest vehicle that can be lifted?

13.67 A water pipe narrows from a radius of $r_1 = 5.00$ cm to a radius of $r_2 = 2.00$ cm If the speed of the water in the wider part of the pipe is 2.00 m/s, what is the speed of the water in the narrower part?

13.68 Donald Duck and his nephews manage to sink Uncle Scrooge's yacht ($m = 4500$ kg), which is made of steel $\left(\rho = 7800 \text{ kg/m}^3\right)$. In typical comic-book fashion, they decide to raise the yacht by filling it with Ping-Pong balls. A Ping-Pong ball has a mass of 2.7 g and a volume of $3.35 \cdot 10^{-5}$ m^3.

a) What is the buoyant force on one Ping-Pong ball in water?

b) How many balls are required to float the ship?

13.69 A wooden block floating in seawater has two thirds of its volume submerged. When the block is placed in mineral oil, 80.0% of its volume is submerged. Find the density of (a) the wooden block and (b) the mineral oil.

13.70 An approximately round tendon that has an average diameter of 3.5 mm and is 15 cm long is found to stretch 0.37 mm when acted on by a force of 13.4 N. Calculate Young's modulus for the tendon.

•13.71 The Jovian moon Europa may have oceans (covered by ice, which can be ignored). What would the pressure be 1.00 km below the surface of a Europan ocean? The surface gravity of Europa is 13.5% that of the Earth's.

•**13.72** Two balls of the same volume are released inside a tank filled with water, as shown in the figure. The densities of balls A and B are 0.90 $\mathrm{g/cm^3}$ and 0.80 $\mathrm{g/cm^3}$ Find the acceleration of (a) ball A and (b) ball B. (c) Which ball wins the race to the top?

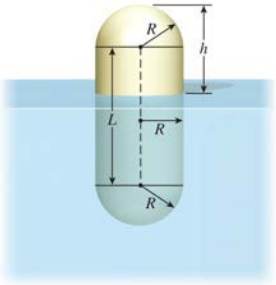
•**13.73** An airplane is moving through the air at a velocity $v = 200.\ \mathrm{m/s}$. Streamlines just over the top of the wing are compressed to 80.0% of their original cross-sectional area, and those under the wing are not compressed at all.

a) Determine the velocity of the air just over the wing.

b) Find the difference in the pressure of the air just over the wing, P, and that of the air under the wing, P'. The density of the air is 1.30 $\mathrm{kg/m^3}$.

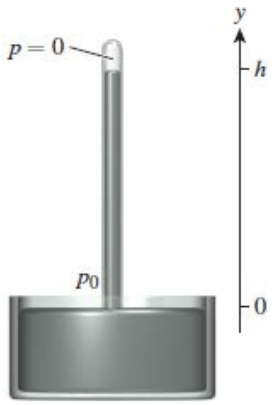
c) Find the net upward force on both wings due to the pressure difference, if the area of the wings is 40.0 $\mathrm{m^2}$.

•**13.74** A cylindrical buoy with hemispherical ends is dropped in seawater of density 1027 $\mathrm{kg/m^3}$, as shown in the figure. The mass of the buoy is 75.0 kg, the radius of the cylinder and the hemispherical caps is $R = 0.200\ \mathrm{m}$, and the length of the cylindrical center section of the buoy is $L = 0.600\ \mathrm{m}$, The lower part of the buoy is weighted so that the buoy is upright in the water, as shown in the figure. In calm water, how high (distance *h*) will the top of the buoy be above the waterline?



•**13.75** Water of density 998.2 $\mathrm{kg/m^3}$ is moving at negligible speed under a pressure of 101.3 kPa but is then accelerated to a high speed by the blades of a spinning propeller. The vapor pressure of the water at the initial temperature of 20.0 $^\circ$C is 2.3388 kPa. At what flow speed will the water begin to boil? This effect, known as *cavitation,* limits the performance of propellers in water. (Vapor pressure is the pressure of the vapor resulting from evaporation of a liquid above a sample of the liquid in a closed container.)

•**13.76** An astronaut wishes to measure the atmospheric pressure on Mars using a mercury barometer like that shown in the figure. The calibration of the barometer is the standard calibration for Earth: 760 mmHg corresponds to the pressure due to Earth's atmosphere, 1 atm or 101.325 kPa. How does the barometer need to be recalibrated for use in the atmosphere of Mars—by what factor does the barometer's scale need to be "stretched"? In her handy table of planetary masses and radii, the astronaut finds that Mars has an average radius of $3.39 \cdot 10^6$ m and a mass of $6.42 \cdot 10^{23}$ kg.



•**13.77** In many locations, such as Lake Washington in Seattle, floating bridges are preferable to conventional bridges. Such a bridge can be constructed out of concrete pontoons, which are essentially concrete boxes filled with air, Styrofoam, or another extremely low-density material. Suppose a floating bridge pontoon is constructed out of concrete and Styrofoam, which have densities of 2200 $\mathrm{kg/m^3}$ and 50.0 $\mathrm{kg/m^3}$. What must the volume ratio of concrete to Styrofoam be if the pontoon is to float with 35.0% of its overall volume above water?

•**13.78** A 1.0-g balloon is filled with helium gas. When a mass of 4.0 g is attached to the balloon, the combined mass hangs in static equilibrium in midair. Assuming that the balloon is spherical, what is its diameter?

•**13.79** A large water tank has an inlet pipe and an outlet pipe. The inlet pipe has a diameter of 2.00 cm and is 1.00 m above the bottom of the tank. The outlet pipe has a diameter of 5.00 cm and is 6.00 m above the bottom of the tank. A volume of 0.300 $\mathrm{m^3}$ of water enters the tank every minute at a gauge pressure of 1.00 atm.

a) What is the velocity of the water in the outlet pipe?

b) What is the gauge pressure in the outlet pipe?

•**13.80** Two spheres of the same diameter (in air), one made of a lead alloy and the other one made of steel, are submerged at a depth $h = 2000.$ m below the surface of the ocean. The ratio of the volumes of the two spheres at this depth is $V_{\mathrm{Steel}}(h)/V_{\mathrm{Lead}}(h) = 1.001206$. Knowing the density of ocean water

$\rho = 1024\ \mathrm{kg/m^3}$ and the bulk modulus of steel, $B_{\mathrm{Steel}} = 160 \cdot 10^9 \mathrm{N/m^2}$, calculate the bulk modulus of the lead alloy.

Even when an object appears to be perfectly at rest, its atoms and molecules are rapidly vibrating. Sometimes these vibrations can be put to use; for example, the atoms in a quartz crystal vibrate with a very steady frequency if the crystal is subjected to a periodic electric field. This vibration is used to keep track of time in modern quartz-crystal clocks and wrist watches. Vibrations of cesium atoms are used in atomic clocks (Figure 14.1).

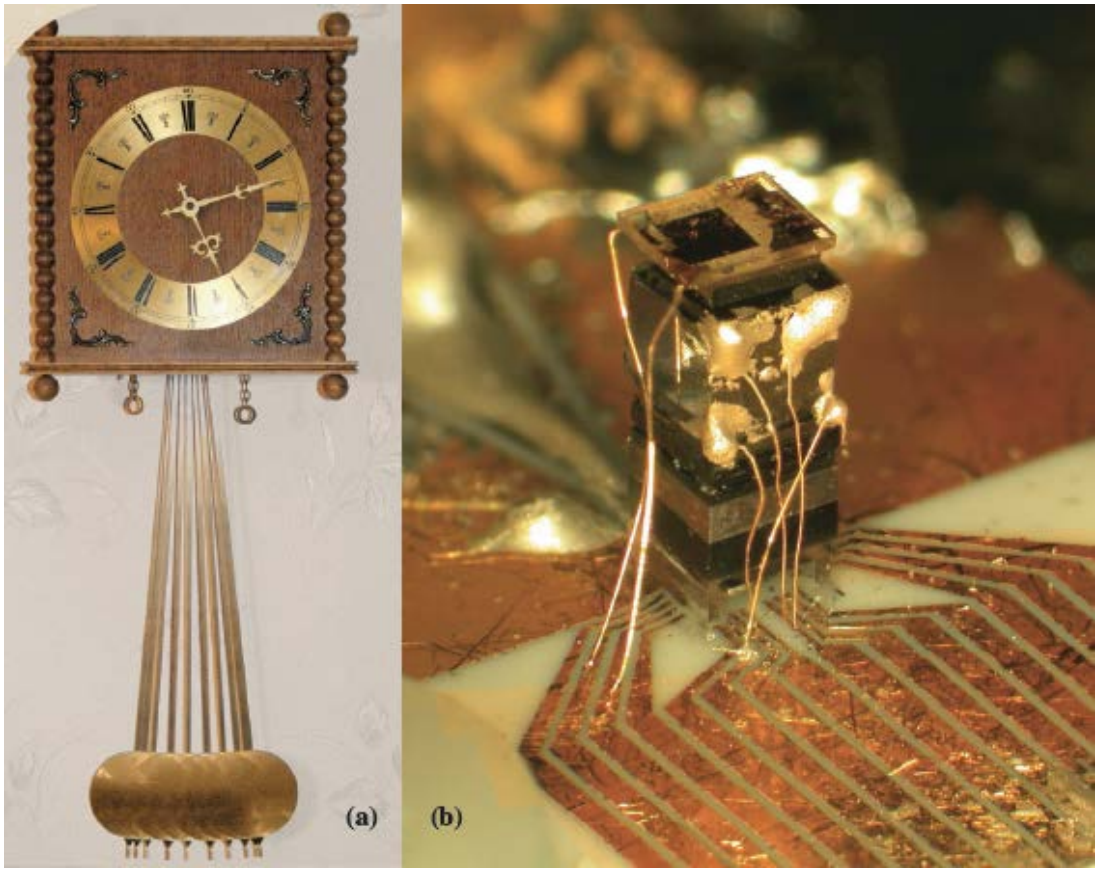

FIGURE 14.1 Harmonic oscillations used for keeping time. (a) Multiple-exposure picture of an old-fashioned pendulum clock. (b) The world's smallest atomic clock, from the National Institute of Standards and Technology, in which cesium atoms perform 9.2 billion oscillations each second. The clock is the size of a grain of rice and is accurate to 1 part in 10 billion—or off by less than 1 s over a period of 300 yr.

a: W. Bauer and G. D. Westfall; **b:** Courtesy National Institute of Standards and Technology

In this chapter, we examine the nature of oscillatory motion. Most of the situations we'll consider involve springs or pendulums, but these are just the simplest examples of oscillators. Later in the book, we will study other kinds of vibrating systems, which can be

modeled as a spring or a pendulum for the purpose of analyzing the motion. In this chapter, we also investigate the concept of resonance, which is an important property of all oscillating systems, from the atomic level to bridges and skyscrapers. Chapters 15 and 16 will apply the concepts of oscillations to analyze the nature of waves and sound.

WHAT WE WILL LEARN

- The spring force leads to a sinusoidal oscillation in time referred to as *simple harmonic motion*.
- A similar force law applies to the oscillation of a pendulum swinging through small angles.
- Oscillations can be represented as a projection of circular motion onto one of the two Cartesian coordinate axes.
- In the presence of damping, oscillations slow down exponentially over time. Depending on the strength of the damping, it is possible that no oscillations will occur.
- Periodic external driving of an oscillator leads to sinusoidal motion at the driving frequency, with a maximum amplitude close to the resonant angular speed.
- Plotting the motion of oscillators in terms of the velocity and position shows that the motion of undamped oscillators follows an ellipse and that of damped oscillators spirals in.
- A damped and driven oscillator can exhibit chaotic motion in which the trajectory in time depends sensitively on the initial conditions.

14.1 Simple Harmonic Motion

Repetitive motion, usually called **periodic motion,** is important in science, engineering, and daily life. Common examples of objects in periodic motion are windshield wipers on a car and the pendulum on a grandfather clock. However, periodic motion is also involved in the alternating current that powers the electronic grid of modern cities, atomic vibrations in molecules, and your own heartbeat and circulatory system.

Simple harmonic motion is a particular type of repetitive motion, which is displayed by a pendulum or by a massive object on a spring. Chapter 5 introduced the spring force, which is described by Hooke's Law: The spring force is proportional to the displacement of the spring from equilibrium. The spring force is a restoring force, always pointing toward the equilibrium position, and is thus opposite in direction to the displacement vector:

$$F_x = -kx.$$

The proportionality constant k is called the *spring constant.*

We have encountered the spring force repeatedly in other chapters. The main reason why forces that depend linearly on displacement are so important in many branches of physics was emphasized in Section 6.4, where we saw that for a system at equilibrium, a small displacement from the equilibrium position results in a springlike force with linear dependence on the displacement from the equilibrium position.

Now let's consider the situation in which an object of mass m is attached to a spring that is then stretched or compressed out of its equilibrium position. When the object is released, it oscillates back and forth. This motion is called **simple harmonic motion (SHM),** and it occurs whenever the restoring force is proportional to the displacement. (As we just noted, a linear restoring force is present in all systems close to a stable equilibrium point, so simple harmonic motion is seen in many physical systems.) Figure 14.2 shows frames of a videotape of the vertical oscillation of a weight on

a spring. A vertical x-axis is superimposed, along with a horizontal axis that represents time, with each frame 0.06 s from the neighboring ones. The red curve running through this sequence is a sine function.

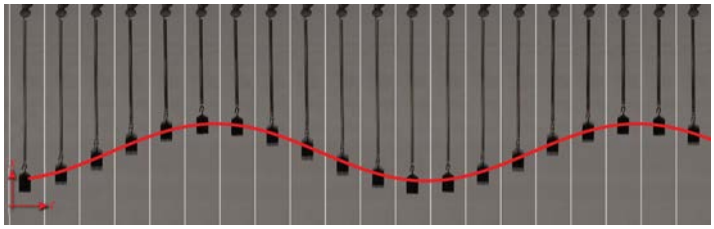

FIGURE 14.2 Consecutive video images of a weight hanging from a spring undergoing simple harmonic motion. A coordinate system and graph of the position as a function of time are superimposed on the images.

W. Bauer and G. D. Westfall

With the insight gained from Figure 14.2, we can describe this type of motion mathematically. We start with the force law for the spring force, $F_x = -kx$, and use Newton's Second Law, $F_x = ma$, to obtain

$$ma = -kx.$$

We know that acceleration is the second time derivative of the position: $a = d^2x/dt^2$. Substituting this expression for a into the preceding equation obtained with Newton's Second Law gives us

$$m\frac{d^2x}{dt^2} = -kx,$$

or

$$\frac{d^2x}{dt^2} + \frac{k}{m}x = 0. \qquad \textbf{(14.1)}$$

Equation 14.1 includes both the position, *x,* and its second derivative with respect to time. Both are functions of the time, *t*. This type of equation is called a *differential equation*. The solution to this particular differential equation is the mathematical description of simple harmonic motion.

From the curve in Figure 14.2, we can see that the solution to the differential equation should be a sine or a cosine function. Let's see if the following will work:

$$x = A\sin(\omega_0 t).$$

The constants A and ω_0 are called the **amplitude** of the oscillation and its **angular speed,** respectively. The amplitude is the maximum displacement away from the equilibrium position, as you learned in Chapter 6. This sinusoidal function works for any value of the amplitude, A. However, the amplitude cannot be arbitrarily large or the spring will be overstretched. On the other hand, we'll see that *not* all values of ω_0 produce a solution.

Taking the second derivative of the trial sine function results in

$$\begin{aligned} x &= A\sin(\omega_0 t) \Rightarrow \\ \frac{dx}{dt} &= \omega_0 A\cos(\omega_0 t) \Rightarrow \\ \frac{d^2x}{dt^2} &= -\omega_0^2\, A\sin(\omega_0 t). \end{aligned}$$

Inserting this result and the sinusoidal expression for *x* into equation 14.1 yields

$$\frac{d^2x}{dt^2} + \frac{k}{m}x = -\omega_0^2 A\sin(\omega_0 t) + \frac{k}{m}A\sin(\omega_0 t) = 0.$$

This condition is fulfilled if $\omega_0^2 = k/m$, or

$$\omega_0 = \sqrt{\frac{k}{m}}.$$

We have thus found a valid solution to the differential equation (equation 14.1). In the same way, we can show that the cosine function leads to a solution as well, also with arbitrary amplitude and with the same angular speed. Thus, the complete solution for constants B and C is

$$x(t) = B\sin(\omega_0 t) + C\cos(\omega_0 t), \text{ with } \omega_0 = \sqrt{\frac{k}{m}}. \quad \textbf{(14.2)}$$

Self-Test Opportunity 14.1

Show that $x(t) = A\sin(\omega_0 t + \theta_0)$, is a solution to equation 14.1.

The units of ω_0 are radians per second (rad/s). When equation 14.2 is applied, $\omega_0 t$ must be expressed in radians, not degrees.

Here is another useful form of equation 14.2:

$$x(t) = A\ \sin(\omega_0 t + \theta_0), \text{ with } \omega_0 = \sqrt{\frac{k}{m}}. \quad \textbf{(14.3)}$$

Self-Test Opportunity 14.2

Show that $A\sin(\omega_0 t + \theta_0) = B\sin(\omega_0 t) + C\cos(\omega_0 t)$, where the relationships between the constants are given in equations 14.4 and 14.5.

This form allows you to see more readily that the motion is sinusoidal. Instead of having two amplitudes for the sine and cosine functions, equation 14.3 has one amplitude, *A,* and a *phase angle,* θ_0. These two constants are related to the constants *B* and *C* of equation 14.2 via

$$A = \sqrt{B^2 + C^2} \tag{14.4}$$

and

$$\theta_0 = \tan^{-1}\left(\frac{C}{B}\right). \tag{14.5}$$

Initial Conditions

How do we determine the values to use for the constants *B* and *C,* the amplitudes of the sine and cosine functions in equation 14.2? The answer is that we need two pieces of information, usually given in the form of the initial position, $x_0 = x(t = 0)$, and initial velocity, $v_0 = v(t = 0) = (dx/dt)|_{t=0}$, as in the following example.

EXAMPLE 14.1 Initial Conditions

PROBLEM 1

A spring with spring constant $k = 56.0\ \mathrm{N/m}$ has a lead weight of mass 1.00 kg attached to its end (Figure 14.3). The weight is pulled $+5.5$ cm from its equilibrium position and then pushed so that it receives an initial velocity of $-0.32\ \mathrm{m/s}$. What is the equation of motion for the resulting oscillation?

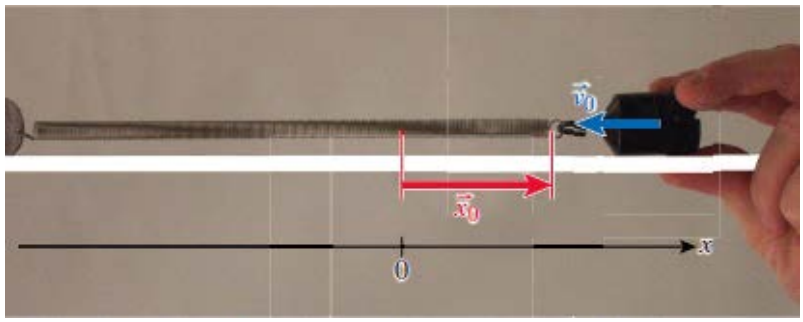

FIGURE 14.3 A weight attached to a spring, with the initial position and velocity vectors shown.

W. Bauer and G. D. Westfall

SOLUTION 1

The general equation of motion for this situation is equation 14.2 for simple harmonic motion:

$$x(t) = B\ \sin(\omega_0 t) + C\cos(\omega_0 t), \quad \text{with} \quad \omega_0 = \sqrt{\frac{k}{m}}.$$

From the data given in the problem statement, we can calculate the angular speed:

$$\omega_0 = \sqrt{\frac{k}{m}} = \sqrt{\frac{56.0\ \mathrm{N/m}}{1.00\ \mathrm{kg}}} = 7.48\ \mathrm{s}^{-1}.$$

Now we must determine the values of the constants B and C.

We take the first derivative of the general equation of motion:

$$X(t) = B\sin(\omega_0 t) + C\cos(\omega_0 t)$$
$$\Rightarrow v(t) = \omega_0 B\cos(\omega_0 t) - \omega_0 C\sin(\omega_0 t).$$

At time $t = 0, \sin(0) = 0$ and $\cos(0) = 1$, so these equations reduce to

$$x_0 = x(t = 0) = C$$
$$v_0 = v(t = 0) = \omega_0 B.$$

We were given the initial conditions for the position, $x_0 = 0.0555\,\text{m}$, and velocity, $v_0 = -0.32\,\text{m/s}$. Thus, we find that $C = x_0 = 0.055\,\text{m}$ and $B = -0.043\,\text{m}$.

PROBLEM 2

What is the amplitude of this oscillation? What is the phase angle?

SOLUTION 2

With the values of the constants B and C, we can calculate the amplitude, A, from equation 14.4:

$$A = \sqrt{B^2 + C^2} = \sqrt{(0.043\,\text{m})^2 + (0.055\,\text{m})^2} = 0.070\,\text{m}.$$

Therefore, the amplitude of this oscillation is 7.0 cm. Note that, as a consequence of the nonzero initial velocity, the amplitude is *not* 5.5 cm, the value of the initial elongation of the spring.

The phase angle is found by application of equation 14.5 taking care to get the correct quadrant for the inverse tangent:

$$\theta_0 = \tan^{-1}\left(\frac{C}{B}\right) = \tan^{-1}\left(-\frac{0.055}{0.043}\right) = 2.234\,\text{rad}.$$

Expressed in degrees, this phase angle is $\theta_0 = 128.0^\circ$.

Position, Velocity, and Acceleration

Let's look again at the relationships of position, velocity, and acceleration. In a form that describes oscillatory motion in terms of amplitude, A, and a phase angle determined by θ_0, they are

$$\begin{aligned} x(t) &= A\sin(\omega_0 t + \theta_0) \\ v(t) &= \omega_0 A\cos(\omega_0 t + \theta_0) \\ a(t) &= -\omega_0^2 A\sin(\omega_0 t + \theta_0). \end{aligned} \qquad \textbf{(14.6)}$$

Here the velocity and acceleration are obtained from the position vector by taking successive time derivatives. These equations suggest that the velocity and acceleration vectors have the same phase angle as the position vector, determined by θ_0, but they have an additional phase angle of $\pi/2$ (for the velocity) and π (for the acceleration), which correspond to the phase difference between the sine and cosine functions and between the sine and the negative sine functions, respectively.

The position, velocity, and acceleration, as given by equations 14.6, are plotted in Figure 14.4, with $\omega_0 = 1.25\,\mathrm{s}^{-1}$ and $\theta_0 = -0.5\,\mathrm{rad}$. Indicated in Figure 14.4 is the phase angle, as well as the three amplitudes of the oscillations: A is the amplitude of the oscillation of the position vector, $\omega_0 A$ (or $1.25A$, in this case) is the amplitude of the oscillation of the velocity vector, and $\omega_0^2 A$ [or $(1.25)^2 A$ here] is the amplitude of the oscillation of the acceleration vector. You can see that whenever the position vector passes through zero, the value of the velocity vector is at a maximum or a minimum, and vice versa. You can also observe that the acceleration (just like the force) is always in the opposite direction to the position vector. When the position passes through zero, so does the acceleration.

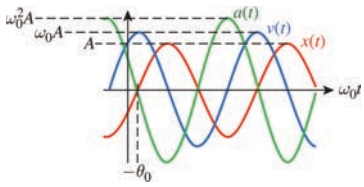

FIGURE 14.4
Graphs of position, velocity, and acceleration for simple harmonic motion as a function of time.

Figure 14.5 shows a block connected to a spring and undergoing simple harmonic motion by sliding on a frictionless surface. The velocity and acceleration vectors of the block at eight different positions are shown. In Figure 14.5a, the block is released from $x = A$. The block accelerates to the left as indicated. The block has reached $x = A/\sqrt{2}$ in Figure 14.5b. At this point, the velocity of the block and the acceleration of the block are directed toward the left. In Figure 14.5c, the block has reached the equilibrium position. The block at this position has zero acceleration and its maximum velocity to the left. The block continues through the equilibrium position of the spring and begins to slow down. In Figure 14.5d, the block is located at $x = -A/\sqrt{2}$. The acceleration of the block is now directed toward the right, although the block is still moving to the left. The block reaches $x = -A$ in Figure 14.5e. At this position, the velocity of the block is zero, and the acceleration of the block is directed toward the right. In Figure 14.5f, the block is again located at $x = -A/\sqrt{2}$, but now the velocity of the block and the acceleration are directed toward the right. The block again reaches the equilibrium position in Figure 14.5g with its velocity vector pointing to the right. The block continues through the equilibrium position and reaches $x = -A/\sqrt{2}$ in Figure 14.5h, where the velocity is still toward the right but the acceleration is now toward the left. The block returns to its original configuration in Figure 14.5a, and the cycle continues.

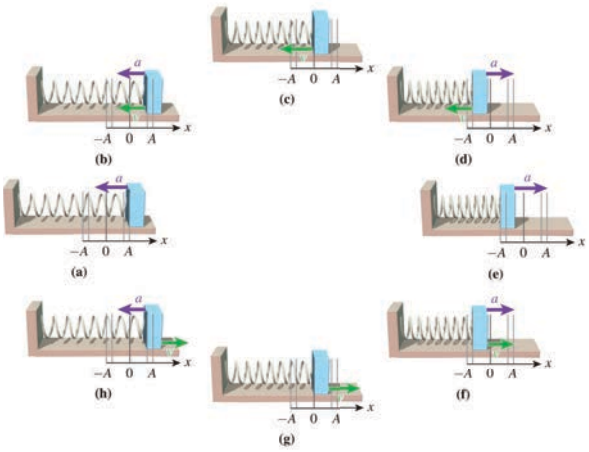

FIGURE 14.5 A block on a spring undergoing simple harmonic motion. The velocity and acceleration vectors are shown at different points in the oscillation: (a)$x = A$; (b)$x = A/\sqrt{2}$; (c)$x = 0$; (d)$x = -A/\sqrt{2}$; (e)$x = -A$; (f) $x = -A/\sqrt{2}$; (g)$x = 0$; (h) $x = A/\sqrt{2}$.

Concept Check 14.1

A spring has a mass attached to its end. The mass is pulled $+2\,\text{cm}$ from the equilibrium position and released. As the mass passes through the equilibrium position, it has a speed of $3.2\,\text{m/s}$. After coming to rest at the equilibrium position, the mass is pulled $+4\,\text{cm}$ from that position and released. The speed of the mass when it next passes through the equilibrium position will be

a) $0.8\,\text{m/s}$.

b) $1.6\,\text{m/s}$.

c) $3.2\,\text{m/s}$.

d) $4.8\,\text{m/s}$.

e) $6.4\,\text{m/s}$.

Period and Frequency

As you know, the sine and cosine functions are periodic, with a period of 2π. The position, velocity, and acceleration for the oscillations of simple harmonic motion are described by a sine or cosine function, and adding a multiple of 2π to the argument of such a function does not change its value:

$$\text{Sin}\,(\omega t) = \sin(2\pi + \omega t) = \sin\left[\omega\left(\frac{2\pi}{\omega} + t\right)\right].$$

(To obtain the right-hand side of this equation, we rewrote the expression in the middle by multiplying and dividing 2π by ω and then factoring out the common factor ω.) We have dropped the index 0 on ω, because we are deriving a universal relationship that is valid for all angular speeds, not just for the particular situation of a mass on a spring.

The time interval over which a sinusoidal function repeats itself is the **period,** denoted by T. From the preceding equation for the periodicity of the sine function, we can see that

$$T = \frac{2\pi}{\omega}, \qquad \textbf{(14.7)}$$

because $\sin(\omega t) = \sin\left[\omega(T + t)\right]$. The same argument works for the cosine function. In other words, replacing t by $t + T$ yields the same position, velocity, and acceleration vectors, as demanded by the definition of the period of simple harmonic motion.

The inverse of the period is the **frequency,** f*:*

$$f = \frac{1}{T}, \qquad \textbf{(14.8)}$$

where f is the number of complete oscillations per unit time. For example, if $T = 0.2\,\text{s}$, then 5 oscillations occur in 1 s, and $f = 1/T = 1/(0.2\,\text{s}) = 5.0\,\text{s}^{-1} = 5.0\,\text{Hz}$. Substituting for T from

equation 14.7 into equation 14.8 yields an expression for the angular speed in terms of the frequency:

$$f = \frac{1}{T} = \frac{1}{2\pi/\omega} = \frac{\omega}{2\pi}$$

or

$$\omega = 2\pi f. \tag{14.9}$$

Page 438

For a mass on a spring, we have the following for the period and the frequency:

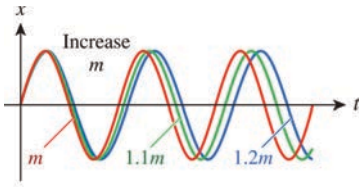
$$T = \frac{2\pi}{\omega_0} = \frac{2\pi}{\sqrt{k/m}} = 2\pi\sqrt{\frac{m}{k}} \tag{14.10}$$

and

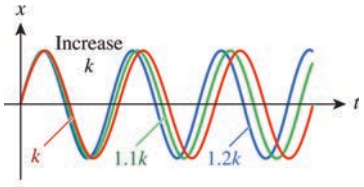
$$f = \frac{\omega_0}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{k}{m}}. \tag{14.11}$$

Interestingly, the period does not depend on the amplitude of the motion.

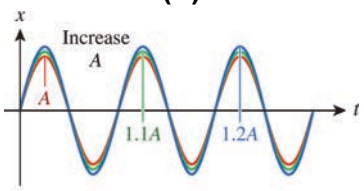
Figure 14.6 illustrates the effect of changing the values of the variables affecting the simple harmonic motion of an object on a spring. The simple harmonic motion is described by equation 14.3 with $\theta_0 = 0$:



(a)



(b)



(c)

FIGURE 14.6 The effect on the simple harmonic motion of an object connected to a spring resulting from increasing (a) the mass, *m;* (b) the spring constant, *k;* and (c) the amplitude, *A.*

$$x = A \sin\left(\sqrt{\frac{k}{m}}t\right).$$

From Figure 14.6a, you can see that increasing the mass, m, increases the period of the oscillations. Figure 14.6b shows that increasing the spring constant, k, decreases the period of the oscillations. Figure 14.6c reinforces the earlier conclusion that increasing the amplitude, A, does not change the period of the oscillations.

EXAMPLE 14.2 Tunnel through the Moon

Suppose we could drill a tunnel straight through the center of the Moon, from one side to the other.

PROBLEM

If we released a steel ball of mass 5.0 kg from rest at one end of this tunnel, what would its motion be like?

SOLUTION

From Chapter 12, the magnitude of the gravitational force inside a spherical mass distribution of constant density is $F_g = mgr/R$, where m is the mass acted on, r is the distance from the center of the sphere, and R is the radius of the sphere, with $r < R$. This force points toward the center of the sphere, that is, in the direction opposite to the displacement. In other words, the gravitational force inside a homogeneous spherical mass distribution follows Hooke's Law, $F(x) = -kx$, with a "spring constant" of $k = mg/R$, where g is the gravitational acceleration experienced at the surface.

First, we need to calculate the gravitational acceleration at the surfaceReleasing the ball from the surface of the Moon on the Moon. Since the mass of the Moon is $7.35 \cdot 10^{22}$ kg (1.2% of the mass of Earth) and its radius is $1.735 \cdot 10^{6}$ m (27% of the radius of Earth), we find (see Chapter 12):

$$g_{\mathrm{M}} = \frac{GM_{\mathrm{M}}}{R_{\mathrm{M}}^2} = \frac{\left(6.67 \cdot 10^{-11}\ \mathrm{m^3 kg^{-1} s^{-2}}\right)\left(7.35 \cdot 10^{22}\ \mathrm{kg}\right)}{\left(1.735 \cdot 10^{6}\ \mathrm{m}\right)^2}$$

The acceleration due to gravity at the Moon's surface is approximately a sixth of what it is on the surface of the Earth.

The appropriate equation of motion is equation 14.2:

$$x(t) = B\sin(\omega_0 t) + C\cos(\omega_0 t).$$

Releasing the ball from the surface of the Moon at time $t = 0$ implies that $x(0) = R_{\mathrm{M}} = B\sin(0) + C\cos(0)$, or $C = R_{\mathrm{M}}$. To determine the other initial condition, we use the velocity equation from Example 14.1: $v(t) = \omega_0 B\cos(\omega_0 t) - \omega_0 C\sin(\omega_0 t)$. The ball was released from rest, so $v(0) = 0 = \omega_0 B\cos(0) - \omega_0 C\sin(0) = \omega_0 B$ giving us $B = 0$. Thus, the equation of motion in this case becomes

$$x(t) = R_{\mathrm{M}}\cos(\omega_0 t).$$

The angular speed of the oscillation is

$$\omega_0 = \sqrt{\frac{\mathrm{k}}{m}} = \sqrt{\frac{\mathrm{g_M}}{R_{\mathrm{M}}}} = \sqrt{\frac{1.63\ \mathrm{m/s^2}}{1.735 \cdot 10^6\ \mathrm{m}}} = 9.69 \cdot 10^{-4}\ \mathrm{s^{-1}}$$

Note that the mass of the steel ball turns out to be irrelevant. The period of the oscillation is

$$T = \frac{2\pi}{\omega_0} = 6485\ \mathrm{s}.$$

The steel ball would arrive at the surface on the other side of the Moon 3243 s after it was released, and then oscillate back. Passing through the entire Moon in a little less than an hour would characterize an extremely efficient mode of transportation, especially since no power supply would be needed.

The velocity of the steel ball during its oscillation would be

$$v(t) = \frac{dx}{dt} = -\omega_0 R_{\mathrm{M}}\sin(\omega_0 t).$$

The maximum velocity would be reached as the ball crossed the center of the Moon and would have the numerical value

$$v_{\max} = \omega_0 R_{\mathrm{M}} = \left(9.69 \cdot 10^{-4}\ \mathrm{s}^{-1}\right)\left(1.735 \cdot 10^{6}\ \mathrm{m}\right) = 1680\ \mathrm{m}$$

If the tunnel were big enough, the same motion could be achieved by a vehicle holding one or more people, providing a very efficient means of transportation to the other side of the Moon, without the need for propulsion. During the entire journey, the people inside the vehicle would feel absolute weightlessness, because they would experience no supporting force from the vehicle! In fact, it would not even be necessary to use a vehicle to make this trip—wearing a space suit, you could just jump into the tunnel.

SOLVED PROBLEM 14.1 Block on a Spring

PROBLEM

A 1.55-kg block sliding on a frictionless horizontal plane is connected to a horizontal spring with spring constant $k = 2.55\ \mathrm{N/m}$. The block is pulled to the right a distance $d = 5.75\ \mathrm{cm}$ and released from rest. What is the block's velocity 1.50 s after it is released?

SOLUTION

THINK

The block will undergo simple harmonic motion. We can use the given initial conditions to determine the parameters of the motion. With those parameters, we can calculate the velocity of the block at the specified time.

SKETCH

Figure 14.7 shows the block attached to a spring and displaced a distance *d* from the equilibrium position.

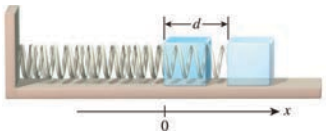


FIGURE 14.7 A block attached to a spring and displaced a distance *d* from the equilibrium position.

RESEARCH

The position of the block undergoing simple harmonic motion is described by equation 14.3. The first initial condition is that at $t = 0$, the position is $x = d$. Thus, we can write

$$x(t=0) = d = A\sin\left[(\omega_0 \cdot 0) + \theta_0\right] = A\sin\theta_0. \quad \text{(i)}$$

We have one equation with two unknowns. To get a second equation, we use the second initial condition: at $t = 0$, the velocity is zero. This leads to

$$v(t=0) = 0 = \omega_0 A\cos\left[(\omega_0 \cdot 0) + \theta_0\right] = \omega_0 A\cos\theta_0, \text{(ii)}$$

We now have two equations and two unknowns.

SIMPLIFY

We can simplify equation (ii) to obtain $\cos\theta_0 = 0$. from which we get the phase angle, $\theta_0 = \pi/2$. Substituting this result into equation (i) gives us

$$d = A\sin\theta_0 = A\sin\left(\frac{\pi}{2}\right) = A.$$

Thus, we can write the velocity as a function of time as

$$v(t) = \omega_0 d\cos\left[\omega_0 t + \left(\frac{\pi}{2}\right)\right] = -\omega_0 d\sin(\omega_0 t).$$

Since the angular speed is given by $\omega_0 = \sqrt{k/m}$, we obtain

$$v(t) = -\sqrt{\frac{k}{m}}d\sin\left(\sqrt{\frac{k}{m}}t\right).$$

CALCULATE

Putting in the numerical values gives us

$$v(t = 1.50\,\mathrm{s}) = -\sqrt{\frac{2.55\,\mathrm{N/m}}{1.55\,\mathrm{kg}}}(0.0575\,\mathrm{m})\,\sin\left[\sqrt{\frac{2.55\,\mathrm{N/m}}{1.55\,\mathrm{kg}}}\right.$$

ROUND

We report our result to three significant figures:

$$v = -0.0692\,\mathrm{m/s} = -6.92\,\mathrm{cm/s}.$$

DOUBLE-CHECK

As usual, it is a good idea to verify that the answer has appropriate units. This is the case here, because meters per second are units for velocity. The maximum speed that the block can attain is $v = \omega_0 d = 7.38\,\mathrm{cm/s}$. The magnitude of our result is less than that maximum speed, so it seems reasonable.

Relationship of Simple Harmonic Motion to Circular Motion

In Chapter 9, we analyzed circular motion along a path of constant radius, r. We saw that the x- and y-coordinates of such motion are given by the equations $x = r\cos\theta$ and $y = \sin\theta$. We also saw that we could express θ as a function of the time t, a constant angular velocity ω, and an initial angle θ_0 as $\theta = \omega t + \theta_0$. We can then express the x- and y-coordinates of circular motion as a function of time as $x(t) = r\cos(\omega t + \theta_0)$ and $y(t) = r\sin(\omega t + \theta_0)$. Figure 14.8a shows how the vector $\overrightarrow{r}(t)$ performs circular motion with constant angular velocity as a function of time and with an initial angle of $\theta_0 = 0$. The red arc segment shows the path of the tip of this radius vector. Figure 14.8b shows the projection of the radius vector onto the y-coordinate. You can clearly see that the motion of the y-component of the radius vector traces out a sine function. The motion of the x-component as a function of time is shown in Figure 14.8c, and it traces out a cosine function. These two projections of circular motion of constant angular velocity exhibit simple harmonic oscillations. This observation makes it clear that the frequency, angular speed, and period defined here for oscillatory motion are identical to the quantities introduced in Chapter 9 for circular motion.

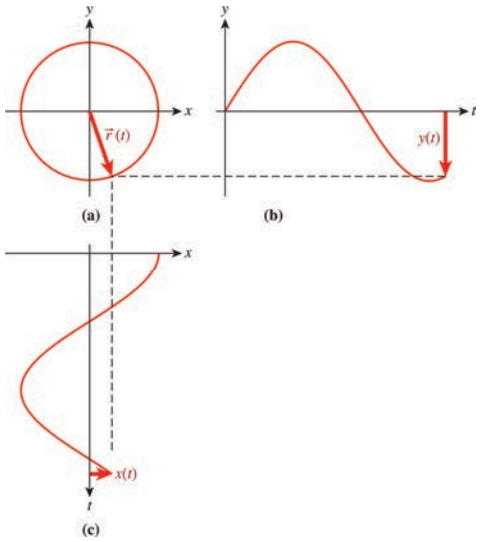

FIGURE 14.8 Projections of the *x*- and *y*-coordinates as a function of time for a position vector with constant length, rotating with constant angular velocity.

In Figure 14.8, the position vector, $\overrightarrow{r}(t)$, originates at $(x, y) = (0, 0)$ and rotates with angular velocity ω. In Chapter 9, we saw that for circular motion the linear velocity, $\overrightarrow{v}(t)$, is tangent to the circle and the linear acceleration, $\overrightarrow{a}(t)$, always points toward the center of the circle. The vectors $\overrightarrow{v}(t)$ and $\overrightarrow{a}(t)$ can be moved so that they originate at $(x, y) = (0, 0)$, as shown in Figure 14.9. Thus, Figure 14.9 shows that, for circular motion, the three vectors $\overrightarrow{r}(t)$, $\overrightarrow{v}(t)$, and $\overrightarrow{a}(t)$ rotate together with angular velocity ω. The linear velocity vector is always 90° out of phase with the position vector, and the linear acceleration vector is always 180° out of phase with the position vector. The projections of the linear velocity and linear acceleration vectors on the *x*- and *y*-axes correspond to the velocity and acceleration of an object undergoing simple harmonic motion.

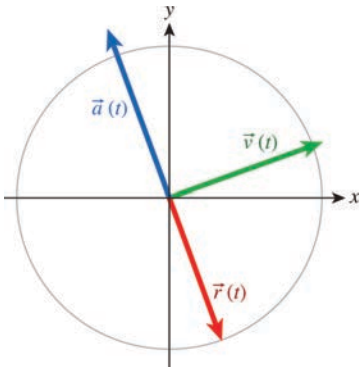

FIGURE 14.9 The position vector, linear velocity vector, and acceleration vector for circular motion.

14.2 Pendulum Motion

We are all familiar with another common oscillating system: the **pendulum.** In its ideal form, a pendulum consists of a thin string attached to a massive object that swings back and forth. The string is assumed to be massless, that is, of such small mass that the mass can be neglected. This assumption is, by the way, a very good approximation to the situation of a person on a swing.

Let's determine the equation of motion for any pendulum-like object. Shown in Figure 14.10 is a ball at the end of a string of length ℓ at an angle θ relative to the vertical. For small angles θ, the differential equation for the motion of the pendulum (which is derived in Derivation 14.1) is

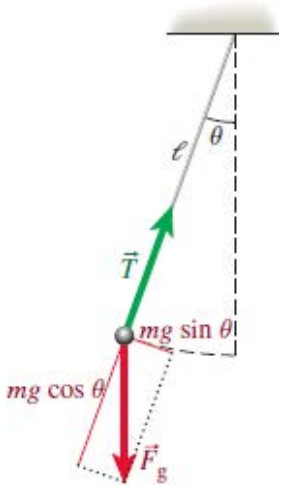

FIGURE 14.10 A pendulum with the force vectors due to gravity and string tension.

$$\frac{d^2\theta}{dt^2} + \frac{g}{\ell}\theta = 0. \qquad \textbf{(14.12)}$$

Equation 14.12 has the solution

$$\sqrt{g}$$

$$\theta(t) = B\ \sin(\omega_0 t) + C\ \cos(\omega_0 t),\ \text{ with }\ \omega_0 = \sqrt{\frac{\omega}{\ell}}. \tag{14.13}$$

DERIVATION 14.1 Pendulum Motion

The displacement, s, of the pendulum in Figure 14.10 is measured along the circumference of a circle with radius ℓ. This displacement can be obtained from the length of the string and the angle: $s = \ell\theta$. Because the length does not change with time, we can write the second derivative of the displacement as

$$\frac{d^2s}{dt^2} = \frac{d^2(\ell\theta)}{dt^2} = \ell\frac{d^2\theta}{dt^2}.$$

The next task is to find the angular acceleration, $d^2\theta/dt^2$, as a function of time. To do this, we need to determine the force that causes the acceleration. Two forces act on the ball: the force of gravity, $\overrightarrow{F}_g$, acting downward, and the force of the tension, $\overrightarrow{T}$, acting along the string. Since the string stays taut and does not stretch, the tension must compensate for the component of the gravitational force along the string. However, the tangential component of the gravitational force vector, $mg \sin\theta$, remains uncompensated for, as shown in Figure 14.10. The net force is always in the direction opposite to the displacement, s.

Using $F_{\text{net}} = ma$, we then obtain

$$\begin{aligned}
m\frac{d^2s}{dt^2} &= -mg\sin\theta \Rightarrow \\
\frac{d^2s}{dt^2} &= -g\ \sin\theta \Rightarrow \\
\ell\frac{d^2s}{dt^2} &+ g\sin\theta = 0 \Rightarrow \\
\frac{d^2\theta}{dt^2} &+ \frac{g}{\ell}\sin\theta = 0.
\end{aligned}$$

This equation is difficult to solve without using the *small-angle approximation*, $\sin\theta \approx \theta$ (in radians). Doing so yields the desired differential equation 14.12. Figure 14.11 shows that the small-angle approximation introduces little error for $\theta < 0.5$ rad (approximately 30°). For these small angles, the motion of a pendulum is approximately simple harmonic motion because the restoring force is approximately proportional to θ.

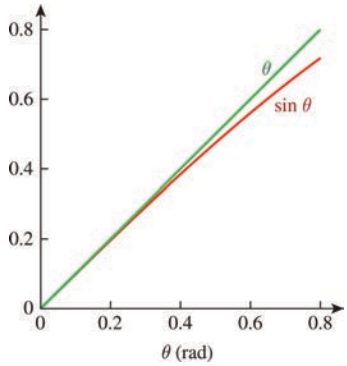

FIGURE 14.11
Graph indicating the error incurred using the small-angle approximation, $\sin\theta \approx \theta$, where θ is measured in radians.

To solve equation 14.12, we could go through exactly the same steps that led to the solution of the differential equation for the spring. However, since equations 14.1 and 14.12 are identical in form, we simply take the solution for spring motion and perform the appropriate substitutions: The angle θ takes the place of x, and g/ℓ takes the place of k/m. In this manner, we arrive at the solution without performing a second derivation.

Self-Test Opportunity 14.3

What is the relationship between the radial component of the gravitational force vector and the string tension?

Period and Frequency of a Pendulum

The period and frequency of a pendulum are related to the angular speed just as for a mass on a spring, but with the angular speed given by $\omega_0 = \sqrt{g/\ell}$:

$$T = \frac{2\pi}{\omega_0} = 2\pi\sqrt{\frac{\ell}{g}} \tag{14.14}$$

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{\ell}}. \tag{14.15}$$

Concept Check 14.2

A pendulum is released from an angle of 60° relative to the vertical and performs simple harmonic oscillations with period *T*. If the initial angle is doubled, to 12.0°, the pendulum will oscillate with period

a) $T/2$.

b) $T/\sqrt{2}$.

c) *T*.

d) $\sqrt{2}T$.

e) $2T$.

Thus, the solution of the equation of motion for the pendulum leads to harmonic motion, just as for the case of a mass on a spring. However, for the pendulum—*unlike* the spring—the frequency is independent of the mass of the oscillating object. This result means that two otherwise identical pendulums with different masses have

the same period. The only way to change the period of a pendulum—other than by taking it to another planet or the Moon, where the gravitational acceleration is different—is by varying its length. (Of course, the gravitational acceleration also has small variations on Earth, for example, depending on altitude; so a pendulum's period is not *exactly* the same everywhere on Earth.)

To shorten the period of a pendulum by a factor of 2 requires shortening the length of the string by a factor of 4. This effect is illustrated in Figure 14.12, which shows the motion of two pendulums, with one four times longer than the other. In this sequence, the shorter pendulum completes two oscillations in the same time in which the longer pendulum completes one.

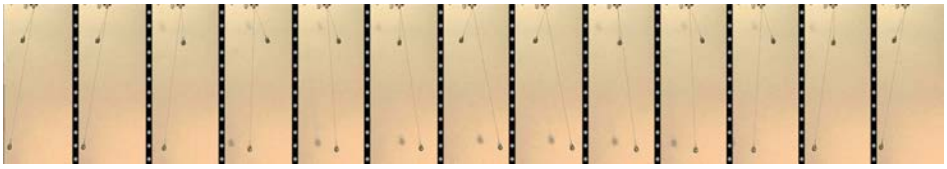

FIGURE 14.12 Video sequence of the oscillation of two pendulums whose lengths have the ratio 4:1.

W. Bauer and G. D. Westfall

Self-Test Opportunity 14.4

You have a pendulum that has the period T on Earth. You take this pendulum to the Moon. What is the period of this pendulum on the Moon in terms of its period on Earth?

EXAMPLE 14.3 Restricted Pendulum

PROBLEM

A pendulum of length 45.3 cm is hanging from the ceiling. Its motion is restricted by a peg that is sticking out of the wall 26.6 cm directly below the pivot point (Figure 14.13). What is the period of oscillation? (Note that specifying the mass is not necessary.)

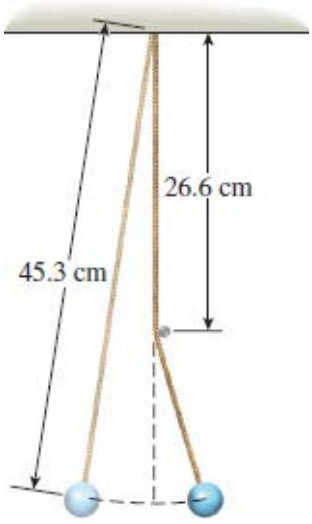

FIGURE 14.13 Restricted pendulum.

SOLUTION

We must solve this problem separately for motion on the left side and on the right side of the peg. On the left side, the pendulum oscillates with its full length, $\ell_1 = 45.3$ cm. On the right side, the pendulum oscillates with a reduced length, $\ell_2 = 45.3\ \text{cm} - 26.6\,\text{cm} = 18.7\,\text{cm}$. On each side, it performs exactly $\frac{1}{2}$ of a full oscillation. Thus, the overall period of the pendulum is $\frac{1}{2}$ of the sum of the two periods calculated with the different lengths:

$$T = \tfrac{1}{2}(T_1 + T_2) = \frac{2\pi}{2}\left(\sqrt{\frac{\ell_1}{g}} + \sqrt{\frac{\ell_2}{g}}\right) = \frac{\pi}{\sqrt{g}}\left(\sqrt{\ell_1} + \sqrt{\right.}$$

$$= \frac{\pi}{\sqrt{9.81\ \mathrm{m/s^2}}}\left(\sqrt{0.453\ \mathrm{m}} + \sqrt{0.187\ \mathrm{m}}\right)$$

$$= 1.11\ \mathrm{s}.$$

Concept Check 14.3

A grandfather clock keeps time using a pendulum consisting of a light rod connected to a small heavy mass. With a rod of length *L*, the period of oscillation is 2.00 s. What should the length of the rod be for the period of the oscillations to be 1.00 s?

a) *L*/4

b) *L*/2

c) *L*

d) 2*L*

e) 4*L*

SOLVED PROBLEM 14.2 Oscillation of a Thin Rod

PROBLEM

A long, thin rod swings about a frictionless pivot at one end. The rod has a mass of 2.50 kg and a length of 1.25 m. The bottom of the rod is pulled to the right until the rod makes an angle $\theta = 20.0^\circ$ with respect to the vertical. The rod is then released from rest and oscillates in simple harmonic motion. What is the period of this motion?

SOLUTION

THINK

We cannot apply the standard analysis to the motion of this pendulum because we must take into account the moment of inertia of the thin rod. This type of pendulum is called a *physical pendulum*. We can relate the torque due to the weight of the rod and acting at its center of gravity to the angular acceleration. From this relationship, we can get a differential equation that has a form similar to that of the equation we derived for a simple pendulum. By analogy to the simple pendulum, we can find the period of the oscillating thin rod.

SKETCH

Figure 14.14 shows the oscillating thin rod.

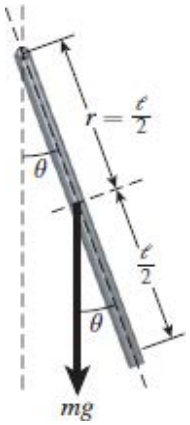

FIGURE 14.14 A physical pendulum consisting of a thin rod swinging from one end.

RESEARCH

Looking at Figure 14.14, we can see that the weight, mg, of the thin rod acts as a force producing a torque of magnitude τ, given by

$$\tau = I\alpha = -mgr\sin\theta, \qquad \textbf{(i)}$$

where I is the moment of inertia, α is the resulting angular acceleration, r is the moment arm, and θ is the angle between the force and the moment arm. The problem states that the initial angular displacement is 20°, so we can use the small-angle approximation, $\sin\theta \approx \theta$. We can then rewrite equation (i) as

$$I\alpha + mgr\theta = 0.$$

We now replace the angular acceleration with the second derivative of the angular displacement and divide through by the moment of inertia, which gives us

$$\frac{d^2\theta}{dt^2} + \frac{mgr}{I}\theta = 0.$$

This differential equation has the same form as equation 14.12; therefore, we can write its solution as

$$\theta(t) = B\sin(\omega_0 t) + C\cos(\omega_0 t), \text{ with } \omega_0 = \sqrt{\tfrac{mgr}{I}}.$$

SIMPLIFY

We can write the period of oscillation of the thin rod:

$$T = \frac{2\pi}{\omega_0} = 2\pi\sqrt{\frac{I}{mgr}}.$$

This result holds in general for the period of a physical pendulum that has moment of inertia I and center of gravity at a distance r from the pivot point. In this case, $r = \ell/2$ and $I = \frac{1}{3}m\ell^2$, so we have

$$T = 2\pi\sqrt{\frac{\frac{1}{3}m\ell^2}{mg(\ell/2)}} = 2\pi\sqrt{\frac{2\ell}{3g}}.$$

CALCULATE

Putting in the numerical values gives us

$$T = 2\pi\sqrt{\frac{2(1.25\text{ m})}{3(9.81\text{ m/s}^2)}} = 1.83128\text{ s}.$$

ROUND

We report our result to three significant figures:

$$T = 1.83\text{ s}.$$

DOUBLE-CHECK

If the mass m of the rod were concentrated at a point a distance ℓ from the pivot point, the rod would be a simple pendulum and

the period would be

$$T = 2\pi\sqrt{\frac{\ell}{g}} = 2.24\,\text{s}.$$

The period of the thin rod is less than this value, which is reasonable because the mass of the thin rod is spread out over its length rather than being concentrated at the end.

As a second check, we start with $T = 2\pi\sqrt{I/mgr}$ and substitute the expression for the moment of inertia of a point mass moving around a point at a distance r away: $I = mr^2$. Taking $r = \ell$, we get

$$T = 2\pi\sqrt{\frac{m\ell^2}{mg\ell}} = 2\pi\sqrt{\frac{\ell}{g}},$$

which is the result for the period of a simple pendulum.

14.3 Work and Energy in Harmonic Oscillations

The concepts of work and kinetic energy were introduced in Chapter 5. In Chapter 6, we found the potential energy due to the spring force. In this section, we analyze the energies associated with motion of a mass on a spring. Then we'll see that almost all those results are applicable to a pendulum as well, but that we need to correct for the small-angle approximation used in solving the differential equation for pendulum motion.

Mass on a Spring

In Chapter 6, we did not have the equation for the displacement as a function of time at our disposal. However, we derived the potential energy stored in a spring, U_{s}, as

$$U_{\text{s}} = \tfrac{1}{2}kx^2,$$

where k is the spring constant and x is the displacement from the equilibrium position. We also saw that the total mechanical energy of a mass on a spring undergoing oscillations of amplitude A is given by

$$E = \tfrac{1}{2}kA^2.$$

Conservation of total mechanical energy means that this expression gives the value of the energy for any point in the oscillation. Using the law of energy conservation, we can write

$$\tfrac{1}{2}kA^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2.$$

Then we can solve for the velocity as a function of the position:

$$v = \sqrt{(A^2 - x^2)\frac{k}{m}}. \qquad \textbf{(14.16)}$$

The functions $v(t)$ and $x(t)$ given in equations 14.6 describe the oscillation over time of a mass on a spring. We can use these functions to verify the relationship between position and velocity expressed in equation 14.16, which we obtained from energy conservation. In this way, we can directly test whether this new result is consistent with what we found previously. First, we evaluate $A^2 - x^2$:

$$\begin{aligned} A^2 - x^2 &= A^2 - A^2 \sin^2(\omega_0 t + \theta_0) \\ &= A^2 \left[1 - \sin^2(\omega_0 t + \theta_0)\right] \\ &= A^2 \cos^2(\omega_0 t + \theta_0). \end{aligned}$$

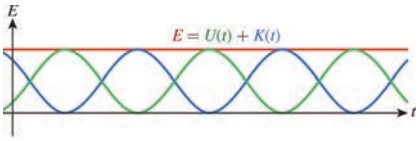
Multiplying both sides by $\omega_0^2 = k/m$, we obtain

$$\frac{k}{m}\left(A^2 - x^2\right) = \frac{k}{m} A^2 \cos^2(\omega_0 t + \theta_0) = v^2.$$

By taking the square root of both sides of this equation, we obtain the same equation for the velocity that we got by applying energy considerations, equation 14.16.

Figure 14.15 illustrates the oscillations of the kinetic and potential energies as a function of time for a mass oscillating on a spring. As you can see, even though the potential and kinetic energies oscillate in time, their sum—the total mechanical energy—is constant. The kinetic energy always reaches its maximum wherever the displacement passes through zero, and the potential energy reaches its maximum for maximum elongation of the spring from the equilibrium position.

(a)



(b)

FIGURE 14.15
Harmonic oscillation of a mass on a spring: (a) displacement as a function of time (same as Figure 14.2); (b) potential and kinetic energies as a function of time on the same time scale.

W. Bauer and G. D. Westfall

The position, velocity, and acceleration vectors at several positions for a block on a spring undergoing simple harmonic motion were shown in Figure 14.5. Figure 14.16 reproduces that figure but also shows the potential and kinetic energies (U and K) at each position. In Figure 14.16a, the block is released from rest at position $x = A$. At this point, all the energy in the system exists in the form of potential energy stored in the spring, and the block has no kinetic energy. The block then accelerates to the left. At $x = A/\sqrt{2}$, shown in Figure 14.16b, the potential energy stored in the spring and the kinetic energy of the block are equal. In Figure 14.16c, the block reaches the equilibrium position of the spring, $x = 0$, at which point the potential energy stored in the spring is zero and the block has its maximum kinetic energy. The block continues moving, through the equilibrium position, and in Figure 14.16d, it is located at $x = -A/\sqrt{2}$. Again the potential energy in the spring and the kinetic energy of the block are equal. In Figure 14.16e, the block is

located at $x = -A$, where the potential energy stored in the spring is at its maximum and the kinetic energy of the block is zero. The block has returned to $x = -A/\sqrt{2}$ in Figure 14.16f, and the potential energy in the spring is again equal to the kinetic energy of the block. In Figure 14.16g, the block is located at $x = 0$, where the potential energy in the spring is zero and the kinetic energy of the block is at its maximum. The block continues through that equilibrium position and reaches $x = A/\sqrt{2}$ in Figure 14.16h, and again the potential energy in the spring is equal to the kinetic energy of the block. The block returns to its original position in Figure 14.16a.

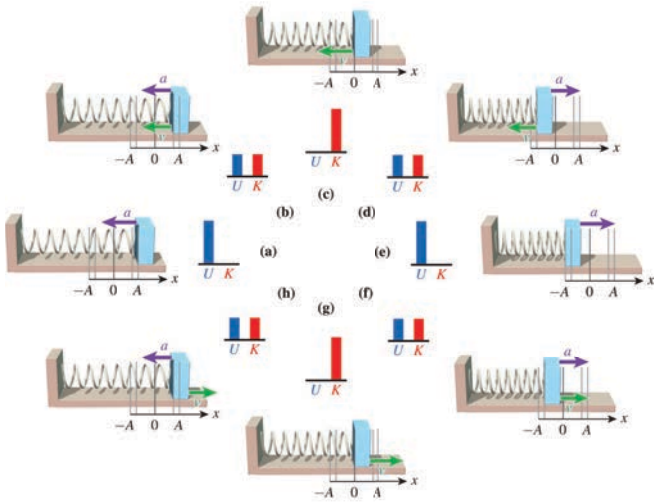


FIGURE 14.16 Position, velocity, and acceleration vectors for a mass on a spring (as in Figure 14.5), with the potential and kinetic energies at each position.

Energy of a Pendulum

In Section 14.2, we saw that the time dependence of the deflection angle of a pendulum is $\theta(t) = \theta_0 \cos\left(\sqrt{g/\ell t}\right)$, if the initial conditions of maximum deflection and zero speed at time zero, $\theta(t = 0) = \theta_0$, are known. We can then find the linear velocity at each point in time by taking the derivative, $d\theta/dt = \omega$, and multiplying this angular velocity by the radius of the circle, ℓ :

$$v = \ell \frac{d\theta(t)}{dt} = -\theta_0 \sqrt{g\ell} \sin\left(\sqrt{\frac{g}{\ell}} t\right).$$

Because $\sin\alpha = \sqrt{1 - \cos^2\alpha}$, we can insert the expression for the deflection angle as a function of time into this equation for the velocity and obtain the speed of the pendulum as a function of the angle:

$$\begin{aligned} |v| &= |\theta_0| \sqrt{g\ell} \left| \sin\left(\sqrt{\frac{g}{\ell}} t\right) \right| \\ &= |\theta_0| \sqrt{g\ell} \sqrt{1 - \cos^2\left(\sqrt{\frac{g}{\ell}} t\right)} \\ &= |\theta_0| \sqrt{g\ell} \sqrt{1 - \frac{\theta^2}{\theta_0^2}} \Rightarrow \\ |v| &= \sqrt{g\ell\left(\theta_0^2 - \theta^2\right)}. \end{aligned} \tag{14.17}$$

What is the energy of the pendulum? At time zero, the pendulum has only gravitational potential energy. We can assign the potential energy a value of zero at the lowest point of the arc. From Figure 14.17, the potential energy at maximum deflection, θ_0, is

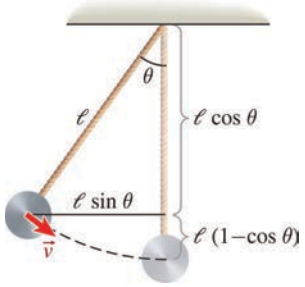

FIGURE 14.17
Geometry of a pendulum.

$$E = K + U = 0 + U = mg\ell(1 - \cos\theta_0).$$

This also gives the value of the total mechanical energy, because by definition the pendulum has zero kinetic energy at the point of maximum deflection, just as a spring does. For any other deflection, the energy is the sum of kinetic and potential energies:

$$E = mg\ell(1 - \cos\theta) + \tfrac{1}{2}mv^2.$$

Combining the preceding two equations for E (because the total energy is conserved) leads to

$$mg\ell(1 - \cos\theta_0) = mg\ell(1 - \cos\theta) + \tfrac{1}{2}mv^2 \Rightarrow$$
$$mg\ell(\cos\theta - \cos\theta_0) = \tfrac{1}{2}mv^2.$$

Solving this equation for the speed (absolute value of the velocity), we obtain

$$|v| = \sqrt{2g\ell(\cos\theta - \cos\theta_0)}. \qquad \textbf{(14.18)}$$

Equation 14.18 is the exact expression for the speed of the pendulum at any angle θ, which we obtained quite straightforwardly

and without the need to solve a differential equation. This equation, however, does not match equation 14.17, which we obtained from the solution of a differential equation. However, remember that we used the small-angle approximation earlier for solving a differential equation. For small angles, we can approximate $\cos\theta \approx 1 - \frac{1}{2}\theta^2 + \cdots$, and so equation 14.17 is a special case of equation 14.18. Our derivation of equation 14.18 using energy considerations did not make use of the small-angle approximation, and thus this equation is valid for all deflection angles. However, the differences between the values obtained with the two equations are quite small, as you can see from Figure 14.18.

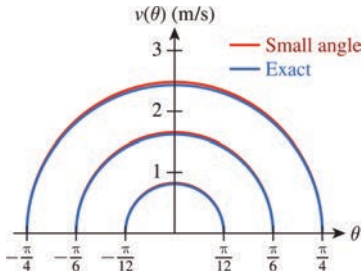

FIGURE 14.18
Comparison of the speeds of a pendulum (of length 1 m) as a function of the deflection angle, calculated with the small-angle approximation (red curves) and the exact formula based on conservation of energy (blue curves). The three sets of curves represent initial angles of $15^\circ, 30^\circ$, and 45° (from inside to outside).

EXAMPLE 14.4 Speed on a Trapeze

PROBLEM

A circus trapeze artist starts her motion on the trapeze from rest with the rope at an angle of 45° relative to the vertical. The rope has a length of 5.00 m. What is her speed at the lowest point in her trajectory?

SOLUTION

The initial condition is $\theta_0 = 45^\circ = \pi/4\,\text{rad}$. We are interested in finding $v(\theta = 0)$. Applying conservation of energy, we use equation 14.18:

$$v(\theta) = \sqrt{2g\ell(\cos\theta - \cos\theta_0)}.$$

Inserting the numbers, we obtain

$$v(\theta) = \sqrt{2\left(9.81\,\text{m/s}^2\right)(5.00\,\text{m})\left(1 - \sqrt{\frac{1}{2}}\right)} = 5.36\,\text{m/s}.$$

With the small-angle approximation, for comparison, we get $v(0) = \theta_0\sqrt{g\ell} = 5.50\,\text{m/s}$. This is close to the exact result but would not be precise enough for many applications.

14.4 Damped Harmonic Motion

Springs and pendulums do not go on oscillating forever; after some time interval, they come to rest. Thus, some force must be present that slows them down. This speed-diminishing effect is called **damping.** An example is shown in Figure 14.19, which shows a mass on a spring oscillating in water, which provides resistance to the motion of the mass and damps it. The center of the mass follows the red curve superimposed on the video frames in Figure 14.19b. The red curve is the product of a plot of simple harmonic motion (orange curve) and an exponentially falling function (yellow curve).

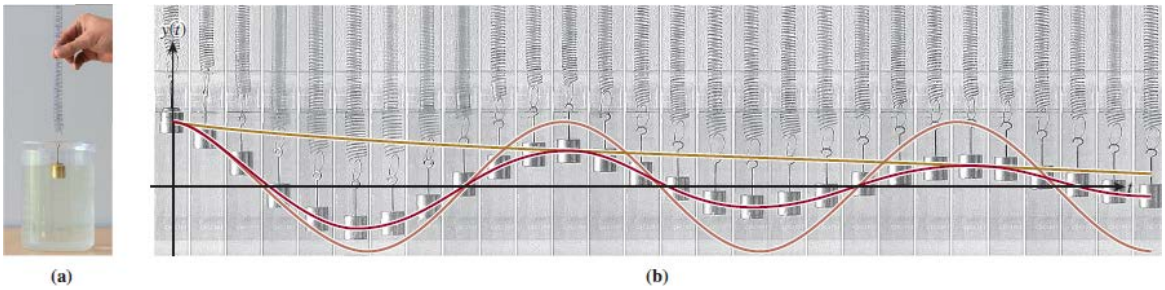

FIGURE 14.19 Example of damped harmonic motion: mass on a spring oscillating in water. (a) Initial conditions. (b) Video frames showing the motion of the mass after it is released.

W. Bauer and G. D. Westfall

In order to quantify the effects of damping, we need to consider the damping force. As we have just seen, a force like the spring force, F_S, which depends linearly on position, does not accomplish damping. However, a force that depends on velocity does. For speeds that are not too large, the damping is given by a drag force of the form $F_\gamma = -bv$, where b is a constant, known as the *damping constant*, and $v = dx/dt$ is the velocity. With this damping force, F_γ, we can write the differential equation describing damped harmonic motion:

$$
\begin{aligned}
ma &= F_\gamma + F_\mathrm{s} \\
m\frac{d^2x}{dt^2} &= -b\frac{dx}{dt} - kx \Rightarrow \\
\frac{d^2x}{dt^2} &+ \frac{b}{m}\frac{dx}{dt} + \frac{k}{m}x = 0.
\end{aligned}
\tag{14.19}
$$

The solution of this equation depends on how large the damping force is relative to the linear restoring force responsible for the harmonic motion. This ratio establishes three general cases: small damping, large damping, and the intermediate case.

Small Damping

For small values of the damping constant b (“small” will be specified below), the solution of equation 14.19 is

$$x(t) = Be^{-\omega_\gamma t}\sin\left(\omega' t\right) + Ce^{-\omega_\gamma t}\cos\left(\omega' t\right). \qquad \textbf{(14.20)}$$

The coefficients B and C are determined by the initial conditions, that is, the position, x_0, and velocity, v_0, at time $t = 0$:

$$B = \frac{v_0 + x_0\omega_\gamma}{\omega'} \text{ and } C = x_0.$$

The angular speeds in this solution are given by

$$\omega_\gamma = \frac{b}{2m}$$

$$\omega' = \sqrt{\omega_0^2 - \omega_\gamma^2} = \sqrt{\frac{k}{m} - \left(\frac{b}{2m}\right)^2}.$$

This solution is valid for all values of the damping constant, b, for which the argument of the square root that determines ω' remains positive:

$$b < 2\sqrt{mk}. \qquad \textbf{(14.21)}$$

This is the condition for small damping, also known as *underdamping*.

DERIVATION 14.2 Small Damping

We can show that equation 14.20 satisfies the differential equation for damped harmonic motion (equation 14.19) in the limit of small damping. We'll start with an assumed solution, which mathematicians call an *Ansatz* (the German word for "attempt"). In order to derive the result from the *Ansatz,* no further knowledge of differential equations is needed; all that is required is taking derivatives.

Ansatz:

$$x(t) = Ce^{-\omega_\gamma t}\cos(\omega' t)$$
$$\Rightarrow \frac{dx}{dt} = -\omega_\gamma Ce^{-\omega_\gamma t}\cos(\omega' t) - \omega'\, Ce^{-\omega_\gamma t}\sin(\omega' t)$$
$$\Rightarrow \frac{d^2x}{dt^2} = \left[\omega_\gamma^2 - (\omega')^2\right]Ce^{-\omega_\gamma t}\cos(\omega' t) + 2\omega_\gamma\omega' Ce^{-\omega_\gamma t}\sin($$

We insert these expressions into equation 14.19:

$$\left[\omega_\gamma^2 - (\omega')^2\right]Ce^{-\omega_\gamma t}\cos(\omega' t) + 2\omega_\gamma\omega' Ce^{-\omega_\gamma t}\sin(\omega' t)$$
$$+\frac{b}{m}\left[-\omega_\gamma Ce^{-\omega_\gamma t}\cos(\omega' t) - \omega' Ce^{-\omega_\gamma t}\sin(\omega' t)\right]$$
$$+\frac{k}{m}\left[Ce^{-\omega_\gamma t}\cos(\omega' t)\right] = 0.$$

Now we rearrange terms:

$$\left[\omega_\gamma^2 - (\omega')^2 - \frac{b}{m}\omega_\gamma + \frac{k}{m}\right]Ce^{-\omega_\gamma t}\cos(\omega' t) + \left(2\omega_\gamma\omega' - \frac{}{}\right.$$

This equation can hold for all times t only if the coefficients in front of the sine and the cosine functions are zero. We thus have two conditions:

$$2\omega_\gamma\omega' - \frac{b}{m}\omega' = 0 \Rightarrow \omega_\gamma = \frac{b}{2m}$$

and

$$\omega_\gamma^2 - \left(\omega'\right)^2 - \frac{b}{m}\omega_\gamma + \frac{k}{m} = 0.$$

To simplify the second condition, we use the first condition, $\omega_\gamma = b/(2m)$, and the expression we obtained earlier for the angular speed for simple harmonic motion, $\omega_0 = \sqrt{k/m}$. We then obtain for the second condition:

$$\left[-\left(\omega'\right)^2 - \omega_\gamma^2 + \omega_0^2\right] = 0 \Rightarrow \omega' = \sqrt{\omega_0^2 - \omega_\gamma^2}.$$

We could go through the same steps to show that $Be^{-\omega_\gamma t}\sin(\omega' t)$ is also a valid solution and could further show that these two solutions are the only possible solutions (but we will skip these demonstrations).

In the derivations in this chapter that involve differential equations we have proceeded in the same manner. This method is a general approach to the solution of problems involving differential equations: Choose a trial solution, and then adjust parameters and make other changes based on the results obtained when the trial solution is substituted into the differential equation.

Just as for the case of undamped motion, we can also write the solution in terms of one amplitude, A, and a phase shift determined by θ_0 instead of using the coefficients B and C for the sine and cosine functions as in equation 14.20:

$$x(t) = Ae^{-\omega_\gamma t}\sin\left(\omega' t + \theta_0\right). \qquad \textbf{(14.22)}$$

Now let's look at a plot of equation 14.20, which describes weakly damped harmonic motion (Figure 14.20). The sine and cosine functions describe the oscillating behavior. Their combination results in another sine function, with a phase shift. The exponential functions that multiply them can be thought of as reducing the amplitude over time. Thus, the oscillations show exponentially decaying amplitude. The angular speed, ω', of oscillation is reduced relative to the angular speed of oscillation without damping, ω_0. The graph in Figure 14.20 was generated with $k = 11.00\,\mathrm{N/m}$, $m = 1.800\,\mathrm{kg}$, and $b = 0.500\,\mathrm{kg/s}$. These parameters result in an angular speed $\omega' = 2.468\,\mathrm{s}^{-1}$, compared to an angular speed $\omega_0 = 2.472\,\mathrm{s}^{-1}$ for the case without damping. The amplitude is $A = 5\,\mathrm{cm}$, and $\theta_0 = 1.6$. The dark blue curve is the plot of the function, and the two light blue curves show the exponential envelope, within which the amplitude is reduced as a function of time.

Position versus time for a weakly damped harmonic oscillator.

EXAMPLE 14.5 Bungee Jumping

A bridge over a deep valley is ideal for bungee jumping. The first part of a bungee jump consists of a free fall of the same length as the unstretched rope. Suppose the height of the bridge is 50.0 m. A 30.0-m-long bungee rope is used and is stretched 5.00 m by the weight of a 70.0-kg person. Thus, the equilibrium length of the bungee rope is 35.0 m. This bungee rope has been found to have a damping angular speed of $\omega_\gamma = 0.300\,\mathrm{s}^{-1}$.

PROBLEM

Describe the vertical motion of the bungee jumper as a function of time.

Page 450

SOLUTION

From the top of the bridge, the jumper experiences free fall for the first 30.0 m of her descent, shown by the red part of the trajectory in Figure 14.21. Once she falls the length of the rope, 30.0 m, she reaches a velocity of $v_0 = -\sqrt{2g\ell} = -24.26\,\mathrm{m/s}$. This part of the trajectory takes time $t = \sqrt{2\ell/g} = 2.47\,\mathrm{s}$.

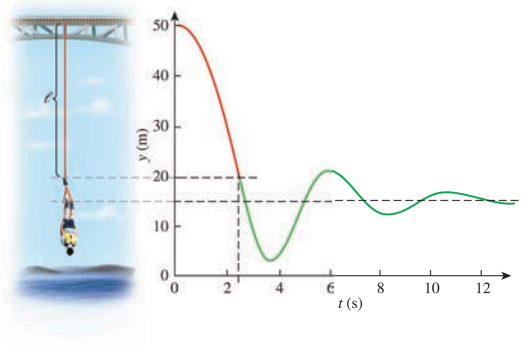

FIGURE 14.21 Idealized vertical motion as a function of time for a bungee jump.

She then enters a damped oscillation $y(t)$ about the equilibrium position, $y_e = 50.0\,\text{m} - 35.0\,\text{m} = 15.0\,\text{m}$, with the initial displacement $y_0 = 50.0\,\text{m}$. We can calculate the angular speed of her vertical motion from knowing that the rope is stretched by 5.00 m due to the 70.0-kg mass and using $mg = k(5.00\,\text{m})$:

$$\omega_0 = \sqrt{\frac{k}{m}} = \sqrt{\frac{g}{\ell_0 - \ell}} = \sqrt{\frac{9.81\ \text{m/s}^2}{5.00\,\text{m}}} = 1.40\,\text{s}^{-1}.$$

Because $\omega_\gamma = 0.300\,\text{s}^{-1}$ was specified, we have $\omega' = \sqrt{\omega_0^2 - \omega_\gamma^2} = 1.37\,\text{s}^{-1}$. The bungee jumper oscillates according to equation 14.20, with coefficients $B = y_0 = 5.00\,\text{m}$ and $C = (v_0 + y_0\omega_\gamma)/\omega' = -16.6\,\text{m/s}$. This motion is represented by the green part of the curve in Figure 14.21.

DISCUSSION

The approximation of damped harmonic motion for the final part of this bungee jump is not quite accurate. If you examine Figure 14.21 carefully, you see that the jumper rises above 20 m for approximately 1 s, starting at approximately 5.5 s. During this interval, the bungee cord is not stretched and so this part of the motion is not sinusoidal. Instead, the bungee jumper is again in free-fall motion. However, for the present qualitative discussion, the approximation of damped harmonic motion is acceptable. If you plan to bungee jump (strongly discouraged in light of past fatalities!), you should always test the setup first with an object of weight equal to or greater than yours.

Large Damping

What happens when the condition for small damping, $b < 2\sqrt{mk}$, is no longer fulfilled? The argument of the square root that determines ω' will be smaller than zero, and so the *Ansatz* we used for small damping does not work anymore. The solution of the differential equation for damped harmonic oscillations (equation 14.19) for the case where $b > 2\sqrt{mk}$, a situation called **overdamping,** is

$$x(t) = Be^{-\left(\omega_\gamma + \sqrt{\omega_\gamma^2 - \omega_0^2}\right)t} + Ce^{-\left(\omega_\gamma - \sqrt{\omega_\gamma^2 - \omega_0^2}\right)t}, \text{ for } b > 2\sqrt{mk}$$

with the amplitudes given by

$$B = \tfrac{1}{2}x_0 - \frac{x_0\omega_\gamma + v_0}{2\sqrt{\omega_\gamma^2 - \omega_0^2}},\ C = \tfrac{1}{2}x_0 + \frac{x_0\omega_\gamma + v_0}{2\sqrt{\omega_\gamma^2 - \omega_0^2}}.$$

Again, we have for the angular speeds

$$\omega_\gamma = \frac{b}{2m},\ \omega_0 = \sqrt{\frac{k}{m}}.$$

The coefficients B and C are determined by the initial conditions.

The solution given by equation 14.23 has no oscillations but instead consists of two exponential terms. The term with the argument $-\omega_\gamma t + \sqrt{\omega_\gamma^2 - \omega_0^2}t$ governs the long-time behavior of the system because it decays more slowly than the other term.

An example of the motion of an overdamped oscillator is graphed in Figure 14.22. The graph was generated for $k = 1.0\,\mathrm{N/m}$, $m = 1.0\,\mathrm{kg}$, and $b = 3.0\,\mathrm{kg/s}$, such that $b(= 3.0\,\mathrm{kg/s}) > 2\sqrt{mk}(= 2\,\mathrm{kg/s})$. These parameters result in an angular speed of $\omega_\gamma = 1.5\,\mathrm{s}^{-1}$, compared to an angular speed of $\omega_0 = 1.0\,\mathrm{s}^{-1}$ for the case without damping. The initial displacement was $x_0 = 5.0\,\mathrm{cm}$, and the system was assumed to be released from rest. The displacement goes to zero without any oscillations.

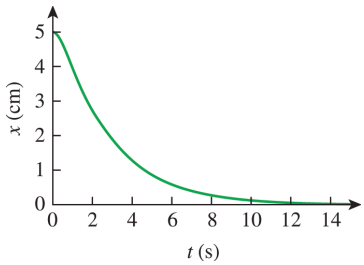

FIGURE 14.22
Position versus time for an overdamped oscillator.

The coefficients B and C can have opposite signs, so the value of x determined from equation 14.23 can change sign one time at most. Physically, this sign change corresponds to the situation in which the oscillator receives a large initial velocity toward the equilibrium position. In that case, the oscillator can overshoot the equilibrium position and approach it from the other side.

Critical Damping

Because we have already covered the solutions of equation 14.19 for $b < 2\sqrt{mk}$ and $b > 2\sqrt{mk}$, you might be tempted to think that we can obtain the solution for $b = 2\sqrt{mk}$ via some limit process or some interpolation between the two solutions. This case, however, is not quite so straightforward, and we have to employ a slightly different *Ansatz*. The solution for the case where $b = 2\sqrt{mk}$, the solution known as **critical damping,** is given by

$$x(t) = Be^{-\omega_\gamma t} + tCe^{-\omega_\gamma t}, \text{ for } b = 2\sqrt{mk}, \qquad \textbf{(14.24)}$$

where the amplitude coefficients have the values

$$B = x_0,\ C = v_0 + x_0\omega_\gamma.$$

The angular speed in this solution is still $\omega_\gamma = b/(2m)$.

Let's look at an example in which the coefficients B and C are determined from the initial conditions for the damped harmonic motion.

EXAMPLE 14.6 Damped Harmonic Motion

PROBLEM

A spring with the spring constant $k = 1.00\ \text{N/m}$ has an object of mass $m = 1.00\ \text{kg}$ attached to it, which moves in a medium with damping constant $b = 2.00\ \text{kg/s}$. The object is released from rest at $x = +5.00\ \text{cm}$ from the equilibrium position. Where will it be after 1.75 s?

SOLUTION

First, we have to decide which of the three types of damping applies in this situation. To find out, we calculate $2\sqrt{mk} = 2\sqrt{(1.00\ \text{kg})(1.00\ \text{N/m})} = 2.00\ \text{kg/s}$, which happens to be exactly equal to the value that was given for the damping constant, b. Therefore, this motion is critically damped. We can also calculate the damping angular speed: $\omega_\gamma = b/(2m) = 1.00\ \text{s}^{-1}$.

The problem statement gives the initial conditions: $x_0 = +5.00\ \text{cm}$ and $v_0 = 0$. We determine the constants B and C from these initial conditions (expressions for these constants). We use equation 14.24 for critical damping:

$$x(t) = Be^{-\omega_\gamma t} + tCe^{-\omega_\gamma t}$$
$$\Rightarrow x(0) = Be^{-\omega_\gamma 0} + 0 \cdot Ce^{-\omega_\gamma 0} = B.$$

Next, we take the time derivative:

$$v = \frac{dx}{dt} = -\omega_\gamma Be^{-\omega_\gamma t} + C(1 - \omega_\gamma t)e^{-\omega_\gamma t}$$
